19.4.5.17 RTCSS_COMP_LSB_REG Register (Offset = 4Ch) [reset = 0h]

RTCSS_COMP_LSB_REG is shown in Figure 19-85 and described in Table 19-90.

The COMP_LSB_REG is used to program the LSB value of the 32 kHz periods to be added to the 32 kHz counter every hour. This is used to compensate the oscillator drift. The COMP_LSB_REG works together with the compensation (MSB) register (COMP_MSB_REG). The AUTOCOMP bit in the control register (CTRL_REG) must be enabled for compensation to take place. This register must be written in two's complement. That means that to add one 32-kHz oscillator period every hour, the ARM must write FFFFh into RTC_COMP_MSB_REG and RTC_COMP_LSB_REG. To remove one 32-kHz oscillator period every hour, the ARM must write 0001h into RTC_COMP_MSB_REG and RTC_COMP_LSB_REG. The 7FFFh value is forbidden.

19.4.5.18 RTCSS_COMP_MSB_REG Register (Offset = 50h) [reset = 0h]

RTCSS_COMP_MSB_REG is shown in Figure 19-86 and described in Table 19-91.

The COMP_MSB_REG is used to program the MSB value of the 32 kHz periods to be added to the 32 kHz counter every hour. This is used to compensate the oscillator drift. The COMP_MSB_REG works together with the compensation (LSB) register (COMP_LSB_REG) to set the hourly oscillator compensation value. The AUTOCOMP bit in the control register (CTRL_REG) must be enabled for compensation to take place. This register must be written in two's complement. That means that to add one 32-kHz oscillator period every hour, the ARM must write FFFFh into RTC_COMP_MSB_REG and RTC_COMP_LSB_REG. To remove one 32-kHz oscillator period every hour, the ARM must write 0001h into RTC_COMP_MSB_REG and RTC_COMP_LSB_REG. The 7FFFh value is forbidden.

19.4.5.23 RTCSS_KICK0R Register (Offset = 6Ch) [reset = 0h]

RTCSS_KICK0R is shown in Figure 19-91 and described in Table 19-96.

The kick registers (KICKnR) are used to enable and disable write protection on the RTC registers. Out of reset, the RTC registers are write-protected. To disable write protection, correct keys must be written to the KICKnR registers. The Kick0 register allows writing to unlock the kick0 data. To disable RTC register write protection, the value of 83E7 0B13h must be written to KICK0R, followed by the value of 95A4 F1E0h written to KICK1R. RTC register write protection is enabled when any value is written to KICK0R.

Table 19-107. RTCSS_PMIC Register Field Descriptions

Bit	Field	Type	Reset	Description
31-19	RESERVED	R	0h	
18-17	PWR_EN_SM	R	0h	Power state machine state. 0h (R/W) = Idle/Default 1h (R/W) = Shutdown (ALARM2 and PWR_ENABLE_EN is set to 1). Note: 31 us latency from ALARM2 event). 10h (R/W) = Time-based wakeup (ALARM status is set). 11h (R/W) = External-event-based wakeup (one or more bit set in EXT_WAKEUP_STATUS)
16	PWR_EN	R/W	0h	Enable for PMIC_POWER_EN signal 0h (R/W) = Disable. When Disabled, pmic_power_en signal will always be driven as 1, ON state. 1h (R/W) = Enable. When Enabled: pmic_power_en signal will be controlled by ext_wakeup, alarm, and alarm2; ON -> OFF (Turn OFF) only by ALARM2 event; OFF -> ON (TURN ON) only by ALARM event OR ext_wakeup event.
15-12	EXT_WAKEUP_STS	R/W	0h	External wakeup status. Write 1 to clear EXT_WAKEUP_STATUS[n] status of ext_wakeup[n]. 0h (R/W) = External wakeup event has not occurred 1h (R/W) = External wakeup event has occurred
11-8	EXT_WAKEUP_DB_EN	R/W	0h	External wakeup debounce enabled. EXT_WAKEUP_DB_EN[n] controls ext_wakeup[n] 0h (R/W) = Disable 1h (R/W) = Enable. When enabled, RTC_DEBOUNCE_REG defines the debounce time.
7-4	EXT_WAKEUP_POL	R/W	0h	External wakeup inputs polarity. EXT_WAKEUP_POL[n] controls ext_wakeup[n]. 0h (R/W) = Active high 1h (R/W) = Active low
3-0	EXT_WAKEUP_EN	R/W	0h	Enable external wakeup inputs. EXT_WAKEUP_EN[n] controls ext_wakeup[n]. 0h (R/W) = Ext. wakeup disabled 1h (R/W) = Ext. wakeup enabled

19.4.5.35 RTCSS_DEBOUNCE Register (Offset = 9Ch) [reset = 0h]

RTCSS_DEBOUNCE is shown in Figure 19-103 and described in Table 19-108.

The debounce timer uses the 32768-Hz clock. It allows choosing the timing or the accuracy of debouncing . A register receives a bit from the reference pin. You will choose the timing if you use the debouncing like a timer, or you will choose the accuracy if you use the debouncing like a real debouncing. The debouncing will be finished when the reference pin will stay the same value (defined in DEBOUNCE_REG) for a defined time.

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	DEBOUNCE_REG	R/W	0h	Debounce time. A value, n, other than 0 results in a debounce time of 30.52 s*(n+1). 0h (R/W) = Debounce time is 30.52 s.

19.5 WATCHDOG

19.5.1 Introduction

The watchdog timer is an upward counter capable of generating a pulse on the reset pin and an interrupt to the device system modules following an overflow condition. The watchdog timer serves resets to the PRCM module and serves watchdog interrupts to the host ARM. The reset of the PRCM module causes a warm reset of the device.

The watchdog timer can be accessed, loaded, and cleared by registers through the L4 interface. The timer clock input is a 32-kHz clock.

The watchdog timer connects to a single target agent port on the L4 interconnect. The default state of the watchdog timer is enabled and not running.

19.5.1.1 Features

The main features of the watchdog timer controllers are:

- L4 slave interface support:
  - 32-bit data bus width
  - 32-/16-bit access supported
  - 8-bit access not supported
  - 11-bit address bus width
  - Burst mode not supported
  - Write nonposted transaction mode only
- Free-running 32-bit upward counter
- Programmable divider clock source (2n where n = 0-7)
- On-the-fly read/write register (while counting)
- Subset programming model of the GP timer
- The watchdog timers are reset either on power-on or after a warm reset before they start counting.
- Reset or interrupt actions when a timer overflow condition occurs
- The watchdog timer generates a reset or an interrupt in its hardware integration.

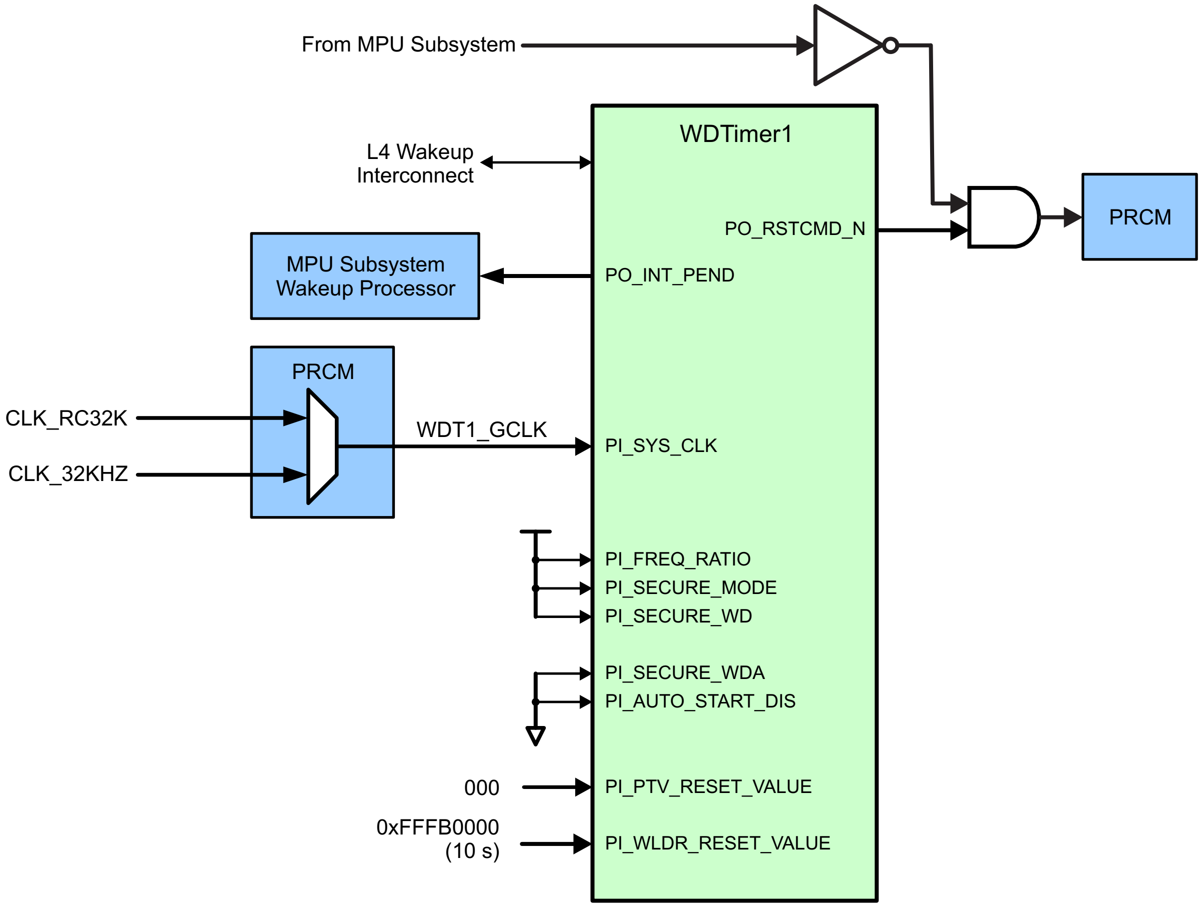
19.5.1.2 Unsupported Featres

There are no unsupported WD Timer features in this device.

19.5.2 Integration

The integration of the public WD Timer is shown in Figure 19-104.

Figure 19-104. Public WDTimer Integration



19.5.2.1 WD Timer Connectivity Attributes

The general connectivity for the public WD Timer module in this device is shown in Table 19-109.

Table 19-109. Public WD Timer Module Connectivity Attributes

Attributes	Type
Power Domain	Wakeup Domain
Clock Domain	PD_WKUP_L4_WKUP_GCLK (OCP) PD_WKUP_WDT1_GCLK (Func)
Reset Signals	WKUP_DOM_RST_N
Idle/Wakeup Signals	Smart Idle / Slave Wakeup
Interrupt Requests	1 Interrupt to MPU Subsystem (WDT1INT) and Wakeup Processor SWakeup Interrupt to Wakeup Processor
DMA Requests	None
Physical Address	L4 Wakeup slave port

19.5.2.2 WD Timer Clock and Reset Management

The Public Watchdog Timer functional clock (pi_sys_clk input) is sourced from either the on-chip ~32768 Hz oscillator (CLK_RC32K) or the PER PLL generated 32.768 KHz clock (CLK_32KHZ) as selected using CLKSEL_WDT1_CLK[CLKSEL] in the PRCM.

Table 19-110. Public WD Timer Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
PI_OCP_CLK Interface clock	26 MHz	CLK_M_OSC	pd_wkup_l4_wkup_gclk from PRCM
PI_SYS_CLK Functional clock	32768 Hz	CLK_RC32K or CLK_32KHZ (PER_CLKOUTM2 / 5859.375)	pd_wkup_wdt1_gclk from PRCM

19.5.3 Functional Description

19.5.3.1 Power Management

There are two clock domains in the watchdog timers:

- Functional clock domain: WDTi_FCLK is a 32 kHz watchdog timer functional clock. It is used to clock the watchdog timer internal logic.
- Interface clock domain: WDTi_ICLK is a 125 MHz watchdog timer interface clock. It is used to synchronize the watchdog timer L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to WDTi_ICLK.

In this device, the clocks to the watchdog timers are always On. The clocks cannot be turned off if the watchdog timers are not being used.

19.5.3.2 Interrupts

Table 19-111 list the event flags, and their masks, that cause module interrupts.

Table 19-111. Watchdog Timer Events

Event Flag	Event Mask	Mapping	Comments
WDT_WIRQSTAT[0] EVENT_OVF	WDT_WIRQENSET/WDT_WIRQENCLR[0] OVF_IT_ENA	WDTINT	Watchdog timer overflow
WDT_WIRQSTAT[1] EVENT_DLY	WDT_WIRQENSET/WDT_WIRQENCLR[1] DLY_IT_ENA	WDTINT	Watchdog delay value reached

19.5.3.3 General Watchdog Timer Operation

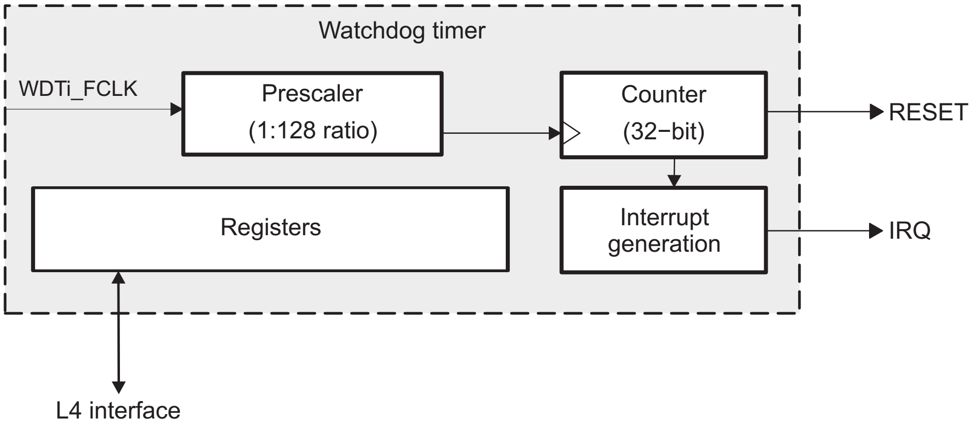
The watchdog timers are based on an upward 32-bit counter coupled with a prescaler. The counter overflow is signaled through two independent signals: a simple reset signal and an interrupt signal, both active low. Figure 19-105 is a functional block diagram of the watchdog timer.

The interrupt generation mechanism is controlled through the WDT_WIRQENSET/WDT_WIRQENCLR and WDT_WIRQSTAT registers.

The prescaler ratio can be set from 1 to 128 by accessing the WDT_WCLR[4:2] PTV bit field and the WDT_WCLR[5] PRE bit of the watchdog control register (WDT_WCLR).

The current timer value can be accessed on-the-fly by reading the watchdog timer counter register (WDT_WCRR), modified by accessing the watchdog timer load register (WDT_WLDR) (no on-the-fly update), or reloaded by following a specific reload sequence on the watchdog timer trigger register (WDT_WTGR). A start/stop sequence applied to the watchdog timer start/stop register (WDT_WSPR) can start and stop the watchdog timers.

Figure 19-105. 32-Bit Watchdog Timer Functional Block Diagram



19.5.3.4 Reset Context

The watchdog timers are enabled after reset. Table 19-112 lists the default reset values of the two watchdog timer load registers (the WDT_WLDR) and prescaler ratios (the WDT_WCLR[4:2] PTV bit field). To get these values, software must read the corresponding WDT_WCLR[4:2] PTV bit field and the 32-bit register to retrieve the static configuration of the module.

Table 19-112. Count and Prescaler Default Reset Values

Timer	WDT_WLDR Reset Value	PTV Reset Value
WDT	FFFF FFBEh	0

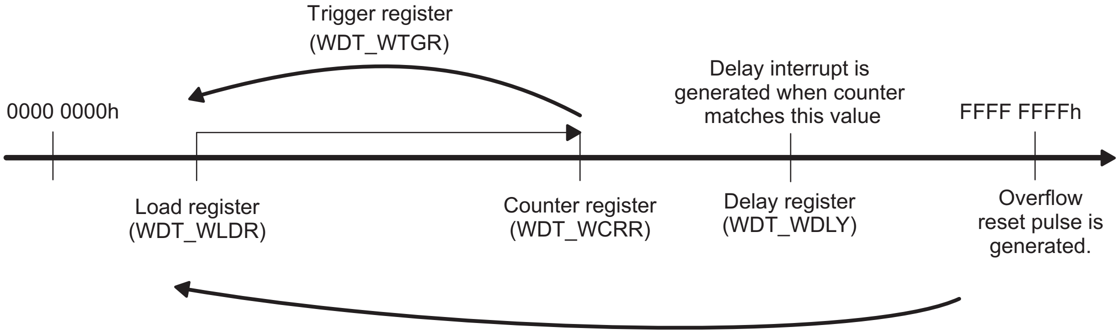
19.5.3.5 Overflow/Reset Generation

When the watchdog timer counter register (WDT_WCRR) overflows, an active-low reset pulse is generated to the PRCM module. This RESET pulse causes the PRCM module to generate global WARM reset of the device, which causes the nRESETIN_OUT pin to be driven out of the device. This pulse is one prescaled timer clock cycle wide and occurs at the same time as the timer counter overflow.

After reset generation, the counter is automatically reloaded with the value stored in the watchdog load register (WDT_WLDR) and the prescaler is reset (the prescaler ratio remains unchanged). When the reset pulse output is generated, the timer counter begins incrementing again.

Figure 19-106 shows a general functional view of the watchdog timers.

Figure 19-106. Watchdog Timers General Functional View



19.5.3.6 Prescaler Value/Timer Reset Frequency

Each watchdog timer is composed of a prescaler stage and a timer counter.

The timer rate is defined by the following values:

- Value of the prescaler fields (the WDT_WCLR[5] PRE bit and the WDT_WCLR[4:2] PTV bit field)
- Value loaded into the timer load register (WDT_WLDR)

The prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio is managed by accessing the ratio definition field (the WDT_WCLR[4:2] PTV bit field) and is enabled with the WDT_WCLR[5] PRE bit.

Table 19-113 lists the prescaler clock ratio values.

Table 19-113. Prescaler Clock Ratio Values

WDT_WCLR[5] PRE	WDT_WCLR[4:2] PTV	Clock Divider (PS)
0	X	1
1	0	1
1	1	2
1	2	4
1	3	8
1	4	16
1	5	32
1	6	64
1	7	128

Thus the watchdog timer overflow rate is expressed as:

OVF_Rate = (FFFF FFFFh – WDT_WLDR + 1) × (wd-functional clock period) × PS

where wd-functional clock period = 1/(wd-functional clock frequency) and PS = $2^{(PTV)}$

CAUTION

Internal resynchronization causes some latency in any software write to WDT_WSPR before WDT_WSPR is updated with the programmed value:

1.5 × functional clock cycles ≤ write_WDT_WSPR_latency ≤ 2.5 × functional clock cycles

Remember to consider this latency whenever the watchdog timer must be started or stopped.

For example, for a timer clock input of 32 kHz with a prescaler ratio value of 1 (clock divided by 2) and WDT_WCLR[5] PRE = 1 (clock divider enabled), the reset period is as listed in Table 19-114.

Table 19-114. Reset Period Examples

WDT_WLDR Value	Reset Period
0000 0000h	74 h 34 min
FFFF 0000h	4 s
FFFF FFF0h	1 ms
FFFF FFFFh	62.5 µs

CAUTION

- Ensure that the reloaded value allows the correct operation of the application. When a watchdog timer is enabled, software must periodically trigger a reload before the counter overflows. Hence, the value of the WDT_WLDR[31:0] bit field must be chosen according to the ongoing activity preceding the watchdog reload.
- Due to design reasons, WDT_WLDR[31:0] = FFFF FFFFh is a special case, although such a value of WDT_WLDR is meaningless. When WDT_WLDR is programmed with the overflow value, a triggering event generates a reset/interrupt one functional clock cycle later, even if the watchdog timer is stopped.

Table 19-115 lists the default reset periods for the watchdog timers.

Table 19-115. Default Watchdog Timer Reset Periods

Watchdog Timers	Clock Source	Default Reset Period
WDT	32 kHz	2 s

19.5.3.7 Triggering a Timer Reload

To reload the timer counter and reset the prescaler before reaching overflow, a reload command is executed by accessing the watchdog timer trigger register (WDT_WTGR) using a specific reload sequence.

The specific reload sequence is performed whenever the written value on the WDT_WTGR register differs from its previous value. In this case, reload is executed in the same way as an overflow autoreload, but without the generation of a reset pulse.

The timer counter is loaded with the value of the watchdog timer load register (the WDT_WLDR[31:0] TIMER_LOAD bit field), and the prescaler is reset.

19.5.3.8 Start/Stop Sequence for Watchdog Timers (Using the WDT_WSPR Register)

To start and stop a watchdog timer, access must be made through the start/stop register (WDT_WSPR) using a specific sequence.

To disable the timer, follow this sequence:

1. Write XXXX AAAAh in WDT_WSPR.
2. Poll for posted write to complete using WDT_WWPS.W_PEND_WSPR.
3. Write XXXX 5555h in WDT_WSPR.
4. Poll for posted write to complete using WDT_WWPS.W_PEND_WSPR.

To enable the timer, follow this sequence:

1. Write XXXX BBBBh in WDT_WSPR.
2. Poll for posted write to complete using WDT_WWPS.W_PEND_WSPR.
3. Write XXXX 4444h in WDT_WSPR.
4. Poll for posted write to complete using WDT_WWPS.W_PEND_WSPR.

All other write sequences on the WDT_WSPR register have no effect on the start/stop feature of the module.

19.5.3.9 Modifying Timer Count/Load Values and Prescaler Setting

To modify the timer counter value (the WDT_WCRR register), prescaler ratio (the WDT_WCLR[4:2] PTV bit field), delay configuration value (the WDT_WDLY[31:0] DLY_VALUE bit field), or the load value (the WDT_WLDR[31:0] TIMER_LOAD bit field), the watchdog timer must be disabled by using the start/stop sequence (the WDT_WSPR register).

After a write access, the load register value and prescaler ratio registers are updated immediately, but new values are considered only after the next consecutive counter overflow or after a new trigger command (the WDT_WTGR register).

19.5.3.10 Watchdog Counter Register Access Restriction (WDT_WCRR Register)

A 32-bit shadow register is implemented to read a coherent value of the WDT_WCRR register because the WDT_WCRR register is directly related to the timer counter value and is updated on the timer clock (WDT_FCLK). The shadow register is updated by a 16-bit LSB read command.

NOTE: Although the L4 clock (WDT_ICLK) is completely asynchronous with the timer clock (WDT_FCLK), some synchronization is performed to ensure that the value of the WDT_WCRR register is not read while it is being incremented.

When 32-bit read access is performed, the shadow register is not updated. Read access is performed directly from the accessed register.

To ensure that a coherent value is read inside WDT_WCRR, the first read access is to the lower 16 bits (offset = 8h), followed by read access to the upper 16 bits (offset = Ah).

19.5.3.11 Watchdog Timer Interrupt Generation

When an interrupt source occurs, the interrupt status bit (the WDT_WIRQSTAT[0] EVENT_OVF or WDT_WIRQSTAT[1] EVENT_DLY bit) is set to 1. The output interrupt line (WDTi_IRQ) is asserted (active low) when status (the EVENT_xxx bit) and enable (the xxx_IT_ENA bit) flags are set to 1; the order is not relevant. Writing 1 to the enable bit (the status is already set at 1) also triggers the interrupt in the normal order (enable first, status next). The pending interrupt event is cleared when the set status bit is overwritten by a value of 1 by a write command in the WDT_WIRQSTAT register. Reading the WDT_WIRQSTAT register and writing the value back allows a fast interrupt acknowledge process.

The watchdog timer issues an overflow interrupt if this interrupt is enabled in the watchdog interrupt enable register (WDT_WIRQENSET[0] OVF_IT_ENA = 1). When the overflow occurs, the interrupt status bit (the WDT_WIRQSTAT[0] EVENT_OVF bit) is set to 1. The output interrupt line (WDT_IRQ) is asserted (active low) when status (EVENT_OVF) and enable (OVF_IT_ENA) flags are set to 1; the order is not relevant. This interrupt can be disabled by setting the WDT_WIRQENCLR[0] OVF_IT_ENA bit to 1.

The watchdog can issue the delay interrupt if this interrupt is enabled in the interrupt enable register (WDT_WIRQENSET[1] DLY_IT_ENA = 1). When the counter is running and the counter value matches the value stored in the delay configuration register (WDT_WDLY), the corresponding interrupt status bit is set in the watchdog status register (WDT_WIRQSTAT) and the output interrupt line is asserted (active low) when the flag (EVENT_DLY) and enable (DLY_IT_ENA) bits are 1 in the WDT_WIRQSTAT and WDT_WIRQENSET registers, respectively; the order (normally enable, then flag), is not relevant. This interrupt can be disabled by setting the WDT_WIRQENCLR[1] DLY_IT_ENA bit to 1.

NOTE: Writing 0 to the WDT_WIRQSTAT[0] EVENT_OVF bit or the WDT_WIRQSTAT[1] EVENT_DLY bit has no effect.

The two clock domains are resynchronized because the interrupt event is generated on the functional clock domain (WDTi_FCLK) during the updating of the interrupt status register (WDT_WIRQSTAT).

The WDT_WDLY register is used to specify the value of the delay configuration register. The delay time to interrupt is the difference between the reload value stored in the counter load register (WDT_WLDR) and the programmed value in this register (WDT_WDLY).

Use the following formula to estimate the delay time:

Delay time period = (WDT_WDLY – WDT_WLDR + 1) × Timer clock period × Clock divider

Where:

- Timer clock period = 1/(Timer clock frequency)
- Clock divider = 2**PTV

If the counter value (WDT_WCRR) reaches the programmed value (WDT_WDLY), the status bit (EVENT_DLY) gets set in the interrupt status register (WDT_WIRQSTAT), and an interrupt occurs if the corresponding enable bit is set in the interrupt enable register (WDT_WIRQENSET).

CAUTION

If the reload event occurs (after a triggering sequence or after a reset sequence) before reaching the programmed value (WDT_WDLY[31:0] WDLY_VALUE), no interrupt is generated.

Also, no interrupt is generated if the value programmed in the delay configuration register (WDT_WDLY) is less than the value stored in the counter load register (WDT_WLDR).

19.5.3.12 Watchdog Timers Under Emulation

To configure the WDT to stop during emulation suspend events (for example, debugger breakpoints), set up the WDT and the Debug Subsystem:

1. Set WDT_WDSC.EMUFREE=0. This will allow the Suspend_Control signal from the Debug Subsystem (Chapter 31) to stop and start the WDT. Note that if EMUFREE=1, the Suspend_Control signal is ignored and the WDT is free running regardless of any debug suspend event. This EMUFREE bit gives local control from a module perspective to gate the suspend signal coming from the Debug Subsystem.
2. Set the appropriate xxx_Suspend_Control register = 0x9, as described in Section 31.1.1.1, *Debug Suspend Support for Peripherals*. Choose the register appropriate to the peripheral you want to suspend during a suspend event.

19.5.3.13 Accessing Watchdog Timer Registers

Posted/nonposted selection applies only to functional registers that require synchronization on/from the timer functional clock domain (WDTi_FCLK). For write/read operation, the following registers are affected:

- WDT_WCLR
- WDT_WCRR
- WDT_WLDR
- WDT_WTGR
- WDT_WDLY
- WDT_WSPR

The timer interface clock domain synchronous registers are not affected by the posted/nonposted selection; the write/read operation is effective and acknowledged (command accepted) after one WDT_ICLK cycle from the command assertion. The timer interface clock domain synchronous registers are:

- WDT_WIDR
- WDT_WDSC
- WDT_WDST
- WDT_WIRQSTATRAW
- WDT_WIRQSTAT
- WDT_WIRQENSET
- WDT_WIRQENCLR
- WDT_WWPS

19.5.3.14 Low-Level Programming Model

This section covers the low-level hardware programming sequences for configuration and use of the module.

19.5.3.14.1 Global Initialization

19.5.3.14.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the watchdog timer is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the watchdog timer (see Table 19-116).

Table 19-116. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	The module interface and functional clocks must be enabled.
Control module	Module-specific pad multiplexing must be set in the control module.
MPU INTC	The MPU INTC configuration must be performed to enable the interrupts from the watchdog timer.

19.5.3.14.1.2 Main Sequence – Watchdog Timer Module Global Initialization

Table 19-117 lists the steps for initializing the watchdog timer module when the module is to be used for the first time.

Table 19-117. Watchdog Timer Module Global Initialization

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	WDT_WDSC[1] SOFTRESET	1
Wait until reset release?	WDT_WDSC[1] SOFTRESET	0
Enable delay interrupt.	WDT_WIRQENSET[1] ENABLE_DLY	1
Enable overflow interrupt.	WDT_WIRQENSET[0] ENABLE_OVF	1

19.5.3.14.2 Operational Mode Configuration

19.5.3.14.2.1 Main Sequence – Watchdog Timer Basic Configuration

Table 19-118 lists the steps for the basic configuration of the watchdog timer.

Table 19-118. Watchdog Timer Basic Configuration

Step	Register/Bit Field/Programming Model	Value
Disable the watchdog timer.	See Section 19.5.3.14.2.2.	
Set prescaler value.	WDT_WCLR[4:2] PTV	xxx
Enable prescaler.	WDT_WCLR[5] PRE	1
Load delay configuration value.	WDT_WDLY	xxx
Load timer counter value.	WDT_WCRR	xxx
Enable the watchdog timer.	See Section 19.5.3.14.2.3.	

19.5.3.14.2.2 Subsequence – Disable the Watchdog Timer

Table 19-119 lists the steps to disable the watchdog timer.

Table 19-119. Disable the Watchdog Timer

Step	Register/Bit Field/Programming Model	Value
Write disable sequence Data1.	WDT_WSPR	XXXX AAAAh
Write disable sequence Data2.	WDT_WSPR	XXXX 5555h

19.5.3.14.2.3 Subsequence – Enable the Watchdog Timer

Table 19-120 lists the steps to enable the watchdog timer.

Table 19-120. Enable the Watchdog Timer

Step	Register/Bit Field/Programming Model	Value
Write enable sequence Data1.	WDT_WSPR	XXXX BBBBh
Write enable sequence Data2.	WDT_WSPR	XXXX 4444h

19.5.4 WDT Registers

Table 19-121 lists the memory-mapped registers for the WDT. All register offset addresses not listed in Table 19-121 should be considered as reserved locations and the register contents should not be modified.

Table 19-121. WDT Registers

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	
5	EMUFREE	R/W	0h	Sensitivity to emulation (debug) suspend event from Debug Subsystem. 0h (R/W) = Timer counter frozen during debug suspend event. 1h (R/W) = Timer counter free-running. Debug suspend event is ignored.
4-3	IDLEMODE	R/W	2h	Configuration of the local target state management mode.By definition, target can handle read/write transaction as long as it is out of IDLE state. 0h (R/W) = Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, i.e. regardless of the IP module's internal requirements. Backup mode, for debug only. 1h (R/W) = No-idle mode: local target never enters idle state.Backup mode, for debug only. 2h (R/W) = Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wakeup events. 3h (R/W) = Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state.
2	RESERVED	R	0h	
1	SOFTRESET	R/W	0h	Software reset. (Optional) 0h (W) = No action 0h (R) = Reset done, no pending action 1h (R) = Reset (software or other) ongoing 1h (W) = Initiate software reset
0	RESERVED	R	0h	

19.5.4.3 WDT_WDST Register (offset = 14h) [reset = 1h]

WDT_WDST is shown in Figure 19-109 and described in Table 19-124.

The Watchdog Status Register provides status information about the module.

Pulse-Width Modulation Subsystem (PWMSS)

This chapter describes the PWMSS of the device.

Topic **Page**

20.1 Pulse-Width Modulation Subsystem (PWMSS)

20.1.1 Introduction

20.1.1.1 Features

The general features of the PWMSS are:

eHRPWM

- Dedicated 16 bit time-base with Period / Frequency control
- Can support 2 independent PWM outputs with Single edge operation
- Can support 2 independent PWM outputs with Dual edge symmetric operation
- Can support 1 independent PWM output with Dual edge asymmetric operation
- Supports Dead-band generation with independent Rising and Falling edge delay control
- Provides asynchronous over-ride control of PWM signals during fault conditions
- Supports “trip zone” allocation of both latched and un-latched fault conditions
- Allows events to trigger both CPU interrupts and start of ADC conversions
- Support PWM chopping by high frequency carrier signal, used for pulse transformer gate drives.
- High-resolution module with programmable delay line.
  - Programmable on a per PWM period basis.
  - Can be inserted either on the rising edge or falling edge of the PWM pulse or both or not at all.

eCAP

- Dedicated input Capture pin
- 32 bit Time Base (counter)
- 4 x 32 bit Time-stamp Capture registers (CAP1-CAP4)
- 4 stage sequencer (Mod4 counter) which is synchronized to external events (ECAPx pin edges)
- Independent Edge polarity (Rising / Falling edge) selection for all 4 events
- Input Capture signal pre-scaling (from 1 to 16)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 Time-stamp events
- Control for continuous Time-stamp captures using a 4 deep circular buffer (CAP1-CAP4) scheme
- Interrupt capabilities on any of the 4 capture events

eQEP

- Input Synchronization
- Quadrature Decoder Unit
- Position Counter and Control unit for position measurement
- Quadrature Edge Capture unit for low speed measurement
- Unit Time base for speed/frequency measurement
- Watchdog Timer for detecting stalls

20.1.1.2 Unsupported Features

The PWMSS module features not supported are shown in Table 20-1.

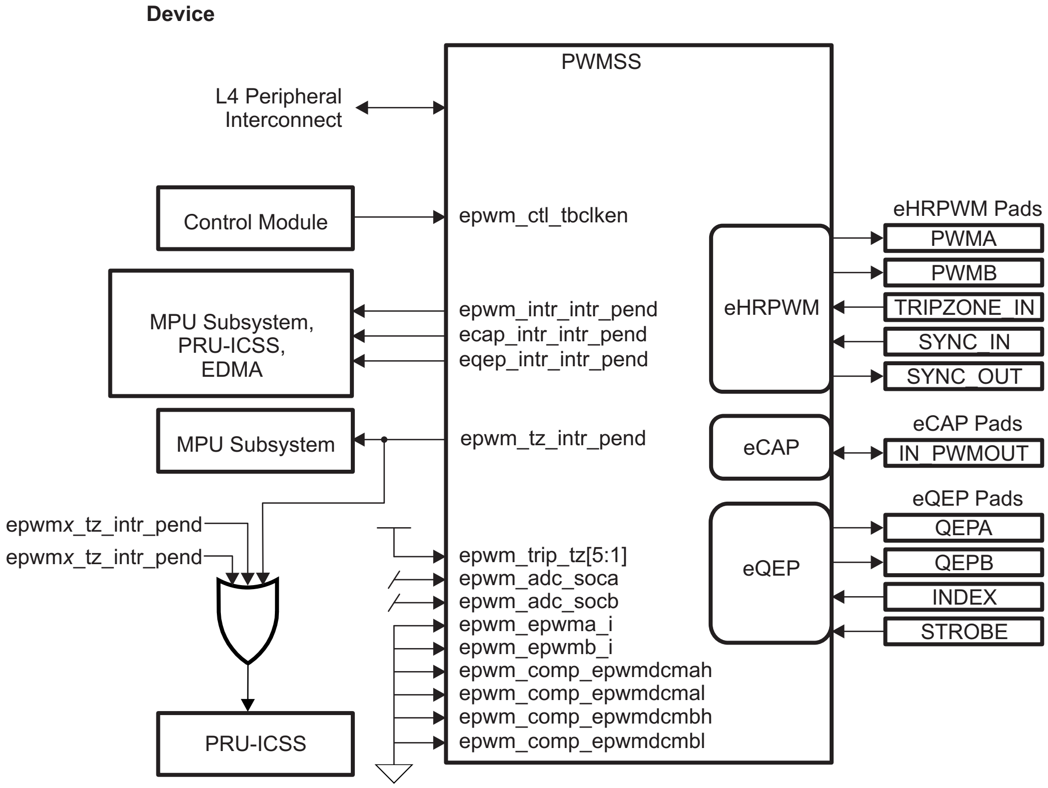
Table 20-1. Unsupported Features

Feature	Reason
ePWM inputs	Not pinned out
ePWM tripzone 1-5 inputs	Only Tripzone0 is pinned out
ePWM digital comparators	Inputs not connected
eQEP quadrature outputs	Only input signals are connected
eCAP3–5	Module not used
eQEP3–5	Module not used

20.1.2 Integration

The Pulse Width Modulation Subsystem (PWMSS) includes a single instance of the Enhanced High Resolution Pulse Width Modulator (eHRPWM), Enhanced Capture (eCAP), and Enhanced Quadrature Encoded Pulse (eQEP) modules. This device includes six instantiations of the PWMSS.

Figure 20-1. PWMSS Integration



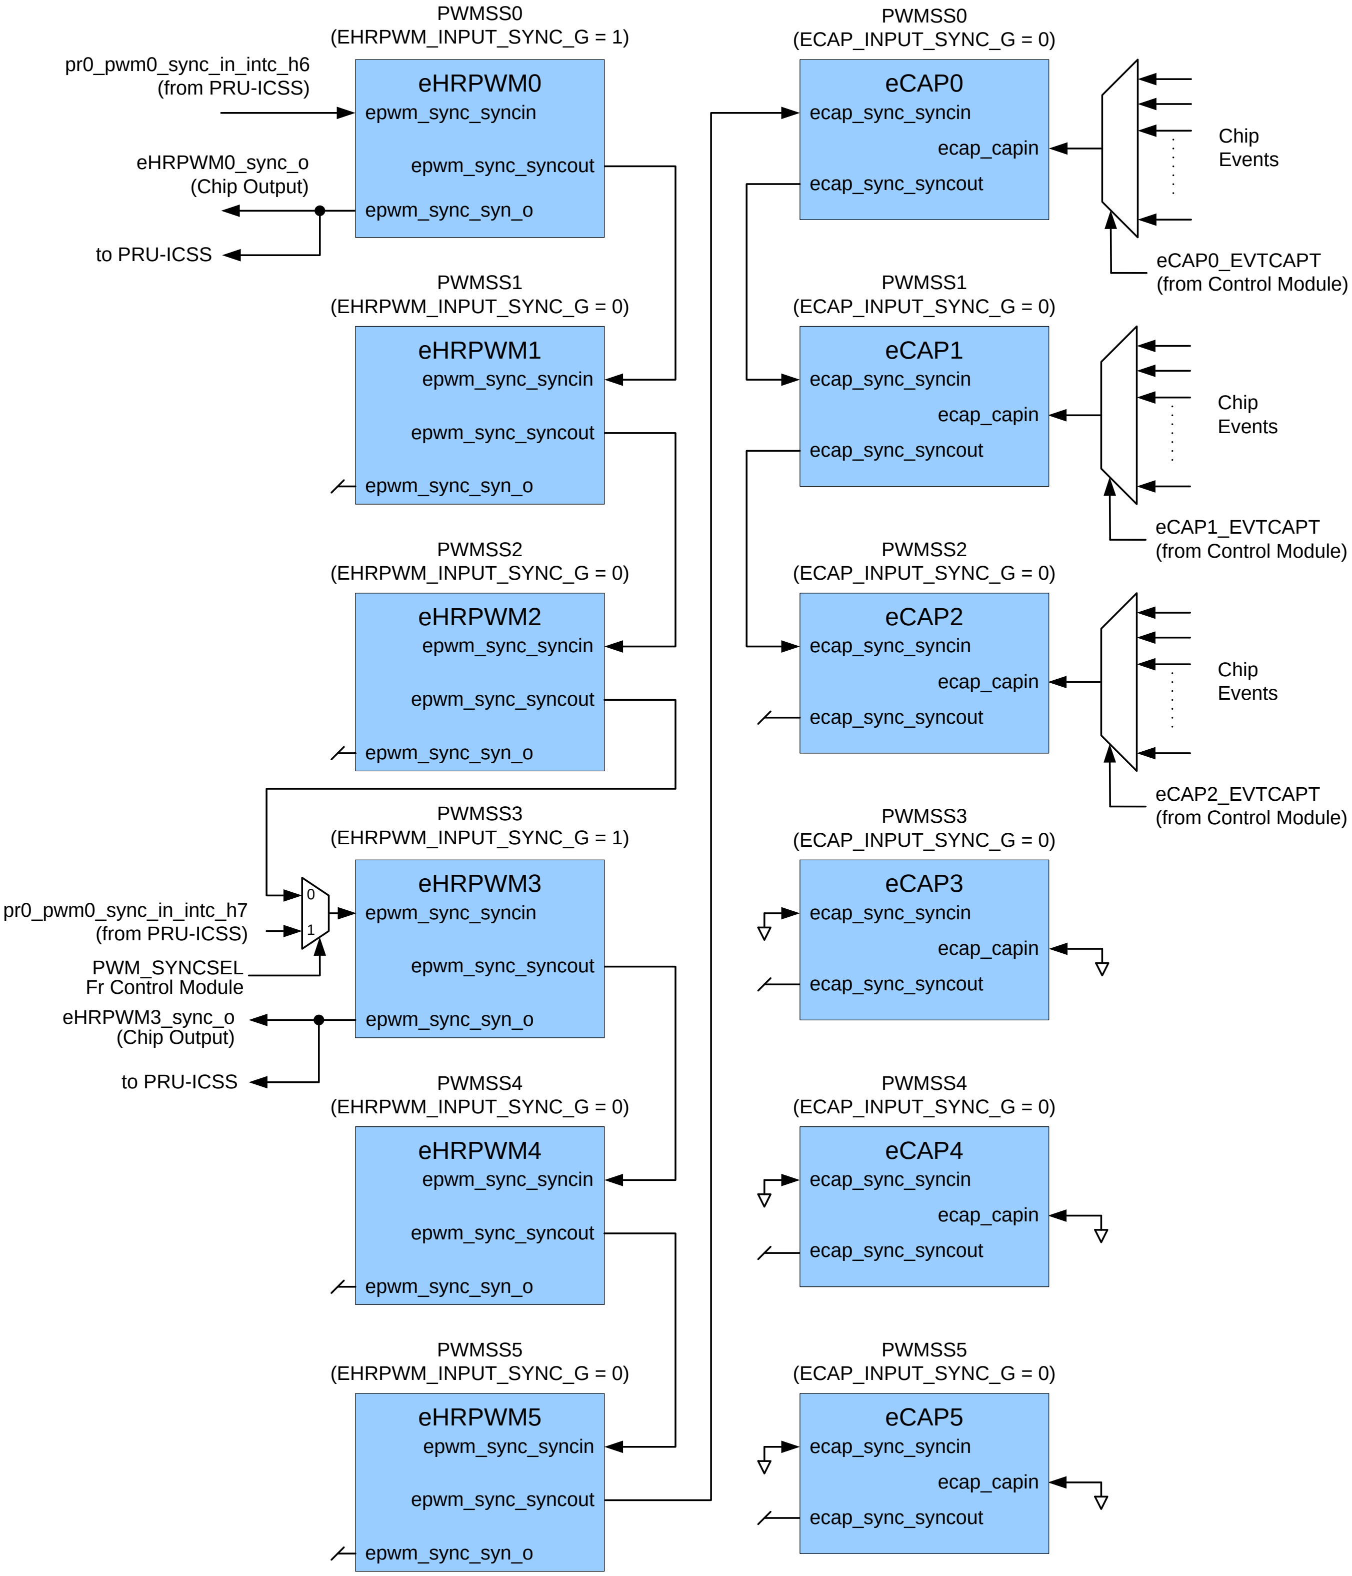
20.1.2.1 PWMSS Synchronization Detail

The PWM (eHRPWM) and capture (eCAP) components of the PWMSS provide synchronization signals to allow them to be synchronized to other modules or events. On this device, these signals are connected in a daisy-chain scheme for PWMSS0–5, as shown in Figure 20-2.

The eCAP capture events may be selected from among 31 different pins or internal interrupt signals, as detailed in Section 8.2. The event is selected using the corresponding ECAPx_EVTCAPT field of the ECAP_EVT_CAP register in the Control Module.

For PWMSS3–5, the eHRPWM modules can be synchronized to a separate external event routed through the PRU-ICSS.

Figure 20-2. PWMSS Synchronization



20.1.2.2 PWMSS Connectivity Attributes

The general connectivity attributes for the PWMSS module are shown in Table 20-2.

The tripzone interrupts from the three PWMSS instantiations (0-2, 3-5) are ORed together to form a single interrupt to the PRU-ICSS but are routed individually to MPU Subsystem, as shown in Figure 20-1.

Table 20-2. PWMSS Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	2 ePWM interrupts per instance epwm_intr_intr - Event interrupt, ePWMxINT for ARM subsystem, epwm_intr_intr_pend for PRU-ICSS epwm_tz_intr - Tripzone interrupt, ePWMx_TZINT for ARM subsystem, pwm_trip_zone for PRU-ICSS (OR'd together as two interrupts, ePWM(0-2) and ePWM(3-5)) 1 eCAP interrupt per instance ecap_intr - Capture/PWM event interrupt, eCAPxINT for ARM subsystem, ecap_intr_intr_pend for PRU-ICSS 1 eQEP Interrupt per instance eqep_intr_intr - Event interrupt, eQEPxINT for ARM subsystem, eqep_intr_intr_pend for PRU-ICSS (only for eQEP0)
DMA Requests	Interrupt requests are redirected as DMA requests: • 1 DMA request from ePWM per instance (ePWMEVTx) • 1 DMA request from eCAP per instance (eCAPEVTx) • 1 DMA request from eQEP per instance (eQEPEVTx)
Physical Address	L4 Peripheral slave port

20.1.2.3 PWMSS Clock and Reset Management

The PWMSS controllers have separate bus interface and functional clocks.

Table 20-3. PWMSS Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
PWMSS_ocp_clk Interface / Functional clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk from PRCM

20.1.2.4 PWMSS Pin list

The external signals for the PWMSS module are shown in the following table.

Table 20-4. PWMSS Pin List

Pin	Type*	Description
EPWMxA	O	PWM output A
EPWMxB	O	PWM output B
EPWM_SYNCIN	I	PWM Sync input
EPWM_SYNCOUT	O	PWM Sync output
EPWM_TRIPZONE[5:0]	I	PWM Tripzone inputs
ECAP_CAPIN_APWMOUT	I/O	eCAP Capture input / PWM output
EQEP_A	I/O	eQEP Quadrature input/output

20.1.3 PWMSS Registers

Table 20-5 lists the memory-mapped registers for the PWMSS. All register offset addresses not listed in Table 20-5 should be considered as reserved locations and the register contents should not be modified.

Table 20-5. PWMSS Registers

Offset	Acronym	Register Name	Section
0h	IDVER	IP Revision Register	Section 20.1.3.1
4h	SYSCONFIG	System Configuration Register	Section 20.1.3.2
8h	CLKCONFIG	Clock Configuration Register	Section 20.1.3.3
Ch	CLKSTATUS	Clock Status Register	Section 20.1.3.4

20.1.3.1 IDVER Register (Offset = 0h) [reset = 40000000h]

IDVER is shown in Figure 20-3 and described in Table 20-6.

Return to Summary Table.

The IP revision register is used by software to track features, bugs, and compatibility.

</table>

Table 20-7. SYSCONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	
5-4	STANDBYMODE	R/W	2h	Configuration of the local initiator state management mode. By definition, initiator may generate read/write transaction as long as it is out of STANDBY state. 0h (R/W) = Force-standby mode: local initiator is unconditionally placed in standby state. Backup mode, for debug only. 1h (R/W) = No-standby mode: local initiator is unconditionally placed out of standby state. Backup mode, for debug only. 2h (R/W) = Smart-standby mode: local initiator standby status depends on local conditions, i.e., the module's functional requirement from the initiator. IP module should not generate (initiator-related) wakeup events.
3-2	IDLEMODE	R/W	2h	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0h (R/W) = Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, i.e. regardless of the IP module's internal requirements. Backup mode, for debug only. 1h (R/W) = No-idle mode: local target never enters idle state. Backup mode, for debug only. 2h (R/W) = Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wakeup events.
1	FREEEMU	R/W	0h	Sensitivity to emulation (debug) suspend event from Debug Subsystem. 0h (R/W) = IP module is sensitive to emulation suspend. 1h (R/W) = IP module is not sensitive to emulation suspend event. Debug suspend event is ignored.
0	SOFTRESET	R/W	0h	Software reset (optional)

20.1.3.3 CLKCONFIG Register (Offset = 8h) [reset = 111h]

CLKCONFIG is shown in Figure 20-5 and described in Table 20-8.

Return to Summary Table.

The clock configuration register is used in the PWMSS submodule for clkstop req and clk_en control. Note: PWMSS Modules Local Clock Gating feature is not supported. This register should not be modified. Clock gating functionality is controlled by PRCM.

0	eCAP_CLK_EN_ACK	R	0h	This bit is the clk_en status output of the eCAP module.

20.2 Enhanced PWM (ePWM) Module

20.2.1 Introduction

An effective PWM peripheral must be able to generate complex pulse width waveforms with minimal CPU overhead or intervention. It needs to be highly programmable and very flexible while being easy to understand and use. The ePWM unit described here addresses these requirements by allocating all needed timing and control resources on a per PWM channel basis. Cross coupling or sharing of resources has been avoided; instead, the ePWM is built up from smaller single channel modules with separate resources and that can operate together as required to form a system. This modular approach results in an orthogonal architecture and provides a more transparent view of the peripheral structure, helping users to understand its operation quickly.

In this chapter, the letter x within a signal or module name is used to indicate a generic ePWM instance on a device. For example, output signals EPWMxA and EPWMxB refer to the output signals from the ePWMx instance. Thus, EPWM1A and EPWM1B belong to ePWM1 and, likewise, EPWM4A and EPWM4B belong to ePWM4.

20.2.1.1 Submodule Overview

The ePWM module represents one complete PWM channel composed of two PWM outputs: EPWMxA and EPWMxB. Multiple ePWM modules are instanced within a device as shown in Figure 20-7. Each ePWM instance is identical with one exception. Some instances include a hardware extension that allows more precise control of the PWM outputs. This extension is the high-resolution pulse width modulator (HRPWM) and is described in Section 20.2.2.10. See Section 20.1.2 to determine which ePWM instances include this feature. Each ePWM module is indicated by a numerical value starting with 1. For example ePWM0 is the first instance and ePWM2 is the third instance in the system and ePWMx indicates any instance.

The ePWM modules are chained together via a clock synchronization scheme that allows them to operate as a single system when required. Additionally, this synchronization scheme can be extended to the capture peripheral modules (eCAP). The number of modules is device-dependent and based on target application needs. Modules can also operate stand-alone.

Each ePWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control
- Two PWM outputs (EPWMxA and EPWMxB) that can be used in the following configurations::
  - Two independent PWM outputs with single-edge operation
  - Two independent PWM outputs with dual-edge symmetric operation
  - One independent PWM output with dual-edge asymmetric operation
- Asynchronous override control of PWM signals through software.
- Programmable phase-control support for lag or lead operation relative to other ePWM modules.
- Hardware-locked (synchronized) phase relationship on a cycle-by-cycle basis.
- Dead-band generation with independent rising and falling edge delay control.
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions.
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs.
- Programmable event prescaling minimizes CPU overhead on interrupts.
- PWM chopping by high-frequency carrier signal, useful for pulse transformer gate drives.

Each ePWM module is connected to the input/output signals shown in Figure 20-7. The signals are described in detail in subsequent sections.

The order in which the ePWM modules are connected may differ from what is shown in Figure 20-7. See Section 20.2.2.3.3.2 for the synchronization scheme for a particular device. Each ePWM module consists of seven submodules and is connected within a system via the signals shown in Figure 20-8.

Figure 20-7. Multiple ePWM Modules

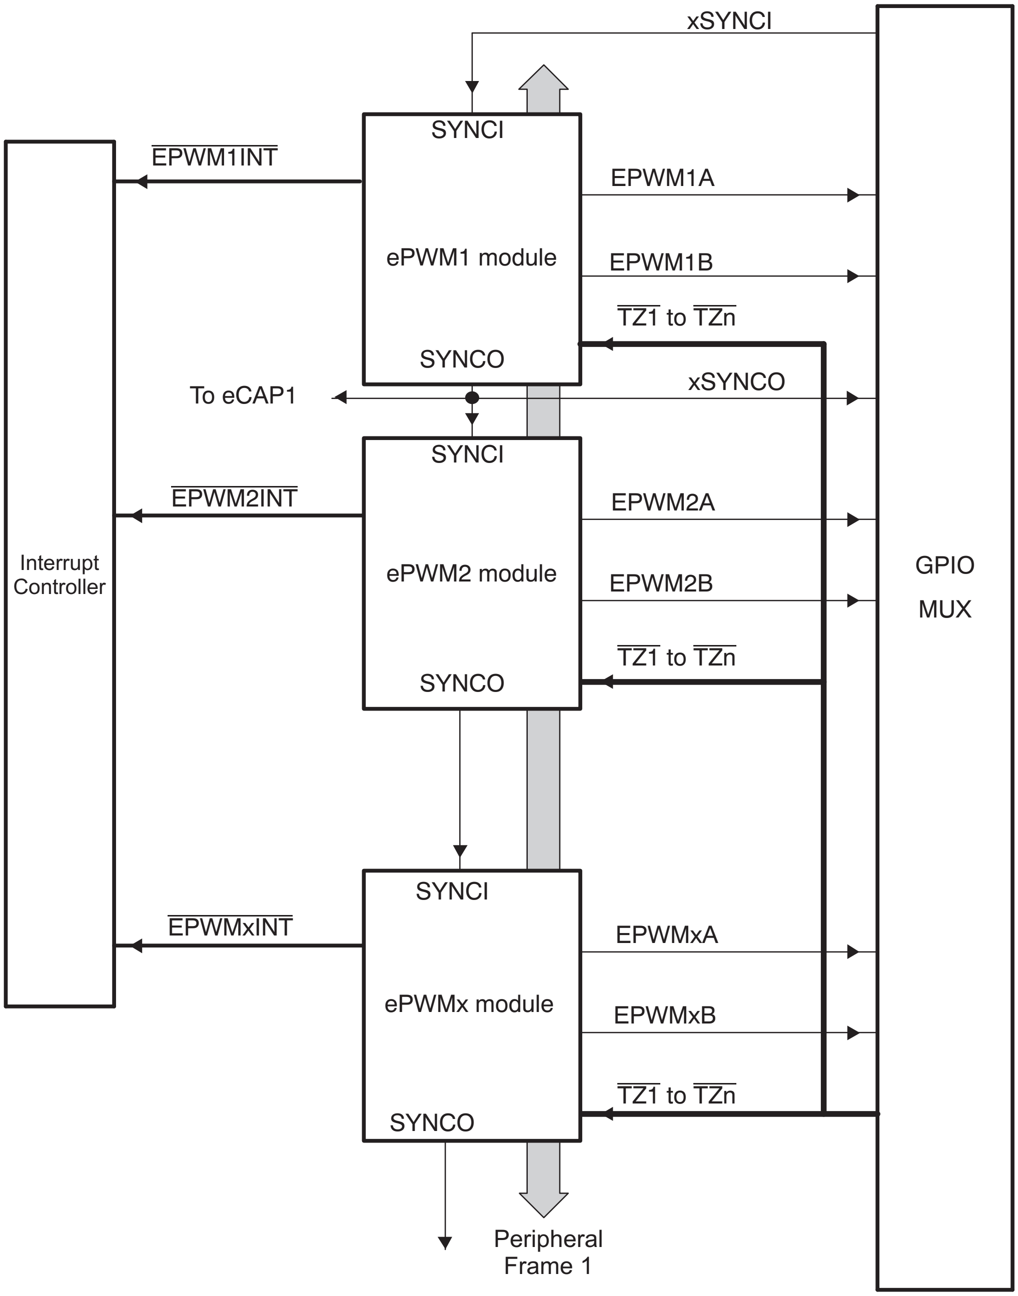

Figure 20-8. Submodules and Signal Connections for an ePWM Module

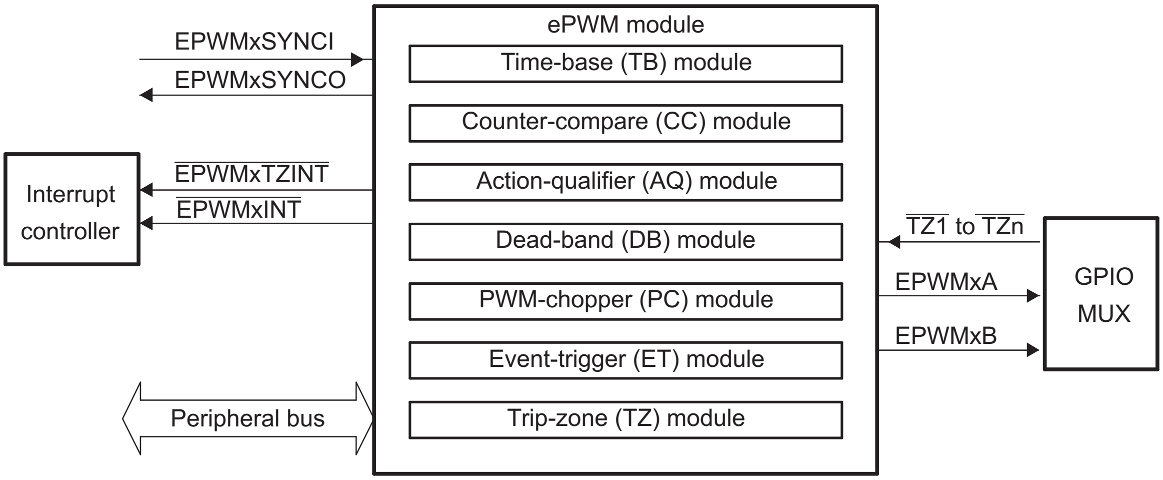

Figure 20-9 shows more internal details of a single ePWM module. The main signals used by the ePWM module are:

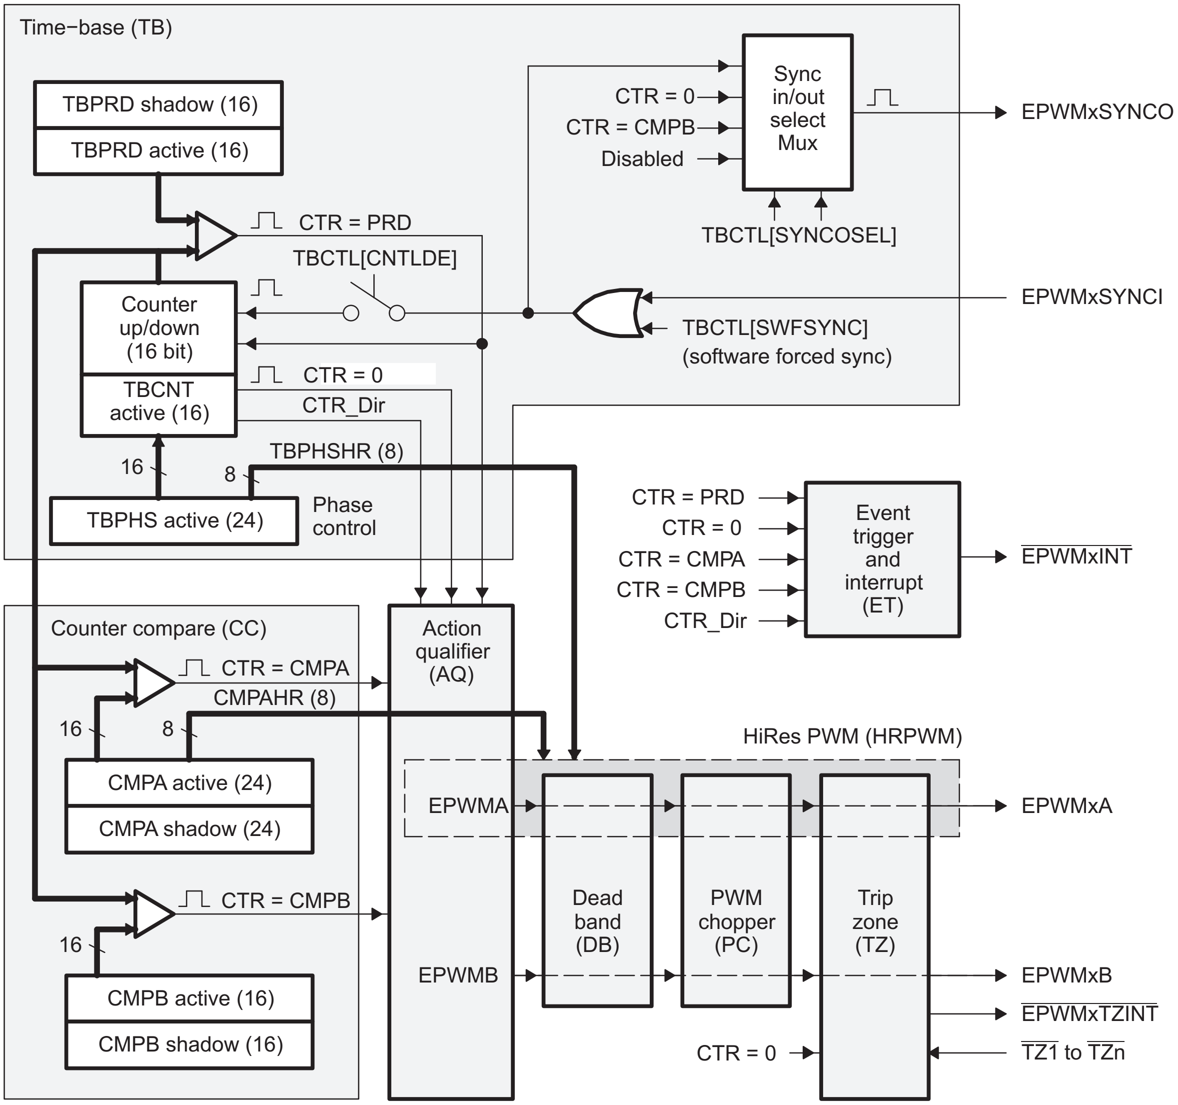
- **PWM output signals (EPWMxA and EPWMxB).** The PWM output signals are made available external to the device through the GPIO peripheral described in the system control and interrupts guide for your device.
- **Trip-zone signals ($\overline{\text{TZ1}}$ to $\overline{\text{TZn}}$).** These input signals alert the ePWM module of an external fault condition. Each module on a device can be configured to either use or ignore any of the trip-zone signals. The trip-zone signal can be configured as an asynchronous input through the GPIO peripheral. See Section 20.1.2 to determine how many trip-zone pins are available in the device.
- **Time-base synchronization input (EPWMxSYNCI) and output (EPWMxSYNCO) signals.** The synchronization signals daisy chain the ePWM modules together. Each module can be configured to either use or ignore its synchronization input. The clock synchronization input and output signal are brought out to pins only for ePWM1 (ePWM module #1). The synchronization output for ePWM1 (EPWM1SYNCO) is also connected to the SYNCI of the first enhanced capture module (eCAP1).
- **Peripheral Bus.** The peripheral bus is 32-bits wide and allows both 16-bit and 32-bit writes to the ePWM register file.

Figure 20-9 also shows the key internal submodule interconnect signals. Each submodule is described in Section 20.2.2.

Figure 20-9. ePWM Submodules and Critical Internal Signal Interconnects



20.2.2 Functional Description

Seven submodules are included in every ePWM peripheral. There are some instances that include a high-resolution submodule that allows more precise control of the PWM outputs. Each of these submodules performs specific tasks that can be configured by software.

20.2.2.1 Overview

Table 20-10 lists the eight key submodules together with a list of their main configuration parameters. For example, if you need to adjust or control the duty cycle of a PWM waveform, then you should see the counter-compare submodule in Section 20.2.2.4 for relevant details.

Table 20-10. Submodule Configuration Parameters

Submodule	Configuration Parameter or Option
Time-base (TB)	• Scale the time-base clock (TBCLK) relative to the system clock (SYSCLKOUT). • Configure the PWM time-base counter (TBCNT) frequency or period. • Set the mode for the time-base counter: – count-up mode: used for asymmetric PWM – count-down mode: used for asymmetric PWM – count-up-and-down mode: used for symmetric PWM • Configure the time-base phase relative to another ePWM module. • Synchronize the time-base counter between modules through hardware or software. • Configure the direction (up or down) of the time-base counter after a synchronization event. • Configure how the time-base counter will behave when the device is halted by an emulator. • Specify the source for the synchronization output of the ePWM module: – Synchronization input signal – Time-base counter equal to zero – Time-base counter equal to counter-compare B (CMPB) – No output synchronization signal generated.
Counter-compare (CC)	• Specify the PWM duty cycle for output EPWMxA and/or output EPWMxB • Specify the time at which switching events occur on the EPWMxA or EPWMxB output
Action-qualifier (AQ)	• Specify the type of action taken when a time-base or counter-compare submodule event occurs: – No action taken – Output EPWMxA and/or EPWMxB switched high – Output EPWMxA and/or EPWMxB switched low – Output EPWMxA and/or EPWMxB toggled • Force the PWM output state through software control • Configure and control the PWM dead-band through software
Dead-band (DB)	• Control of traditional complementary dead-band relationship between upper and lower switches • Specify the output rising-edge-delay value • Specify the output falling-edge delay value • Bypass the dead-band module entirely. In this case the PWM waveform is passed through without modification.
PWM-chopper (PC)	• Create a chopping (carrier) frequency. • Pulse width of the first pulse in the chopped pulse train. • Duty cycle of the second and subsequent pulses. • Bypass the PWM-chopper module entirely. In this case the PWM waveform is passed through without modification.

Table 20-10. Submodule Configuration Parameters (continued)

Submodule	Configuration Parameter or Option
Trip-zone (TZ)	• Configure the ePWM module to react to one, all, or none of the trip-zone pins. • Specify the tripping action taken when a fault occurs: – Force EPWMxA and/or EPWMxB high – Force EPWMxA and/or EPWMxB low – Force EPWMxA and/or EPWMxB to a high-impedance state – Configure EPWMxA and/or EPWMxB to ignore any trip condition. • Configure how often the ePWM will react to each trip-zone pin: – One-shot – Cycle-by-cycle • Enable the trip-zone to initiate an interrupt. • Bypass the trip-zone module entirely.
Event-trigger (ET)	• Enable the ePWM events that will trigger an interrupt. • Specify the rate at which events cause triggers (every occurrence or every second or third occurrence) • Poll, set, or clear event flags
High-Resolution PWM (HRPWM)	• Enable extended time resolution capabilities • Configure finer time granularity control or edge positioning

Code examples are provided in the remainder of this chapter that show how to implement various ePWM module configurations. These examples use the constant definitions shown in Example 20-1.

20.2.2.2 Proper Interrupt Initialization Procedure

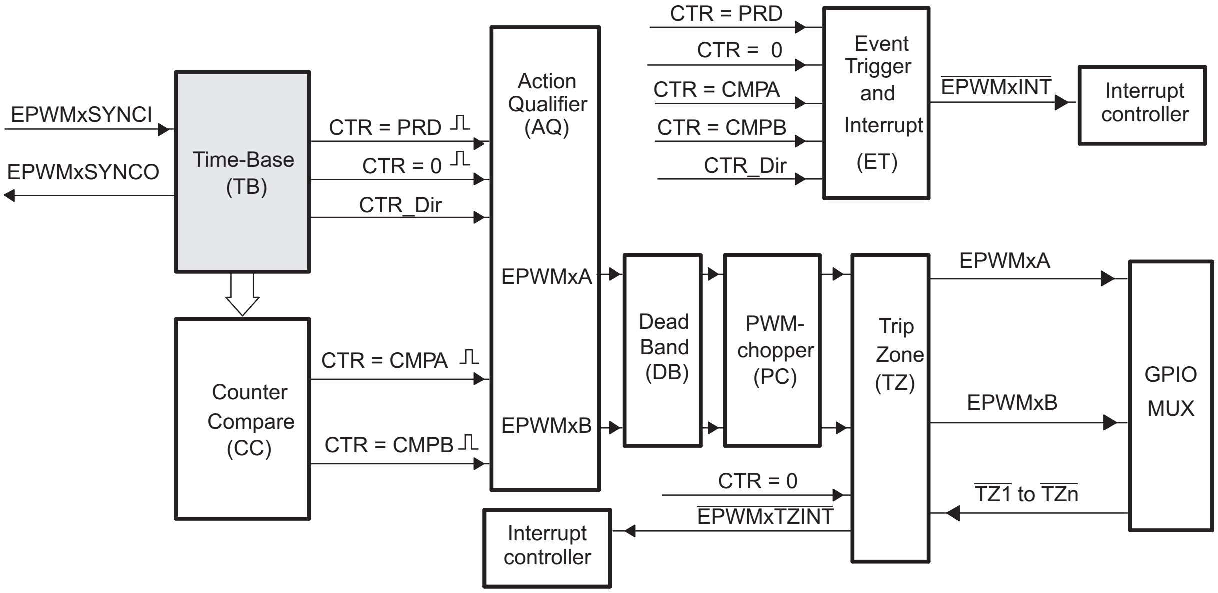
When the ePWM peripheral clock is enabled it may be possible that interrupt flags may be set due to spurious events due to the ePWM registers not being properly initialized. The proper procedure for initializing the ePWM peripheral is:

1. Disable global interrupts (CPU INTM flag)
2. Disable ePWM interrupts
3. Initialize peripheral registers
4. Clear any spurious ePWM flags
5. Enable ePWM interrupts
6. Enable global interrupts

20.2.2.3 Time-Base (TB) Submodule

Each ePWM module has its own time-base submodule that determines all of the event timing for the ePWM module. Built-in synchronization logic allows the time-base of multiple ePWM modules to work together as a single system. Figure 20-10 illustrates the time-base module's place within the ePWM.

Figure 20-10. Time-Base Submodule Block Diagram



20.2.2.3.1 Purpose of the Time-Base Submodule

You can configure the time-base submodule for the following:

- Specify the ePWM time-base counter (TBCNT) frequency or period to control how often events occur.
- Manage time-base synchronization with other ePWM modules.
- Maintain a phase relationship with other ePWM modules.
- Set the time-base counter to count-up, count-down, or count-up-and-down mode.
- Generate the following events:
  - CTR = PRD: Time-base counter equal to the specified period (TBCNT = TBPRD) .
  - CTR = 0: Time-base counter equal to zero (TBCNT = 0000h).
- Configure the rate of the time-base clock; a prescaled version of the CPU system clock (SYSCLKOUT). This allows the time-base counter to increment/decrement at a slower rate.

20.2.2.3.2 Controlling and Monitoring the Time-Base Submodule

Table 20-11 lists the registers used to control and monitor the time-base submodule.

Table 20-11. Time-Base Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
TBCTL	Time-Base Control Register	0h	No
TBSTS	Time-Base Status Register	2h	No
TBPHSHR	HRPWM extension Phase Register (1)	4h	No
TBPHS	Time-Base Phase Register	6h	No
TBCNT	Time-Base Counter Register	8h	No
TBPRD	Time-Base Period Register	Ah	Yes

(1) This register is available only on ePWM instances that include the high-resolution extension (HRPWM). On ePWM modules that do not include the HRPWM, this location is reserved. See Section 20.1.2 to determine which ePWM instances include this feature.

Figure 20-11 shows the critical signals and registers of the time-base submodule. Table 20-12 provides descriptions of the key signals associated with the time-base submodule.

Figure 20-11. Time-Base Submodule Signals and Registers

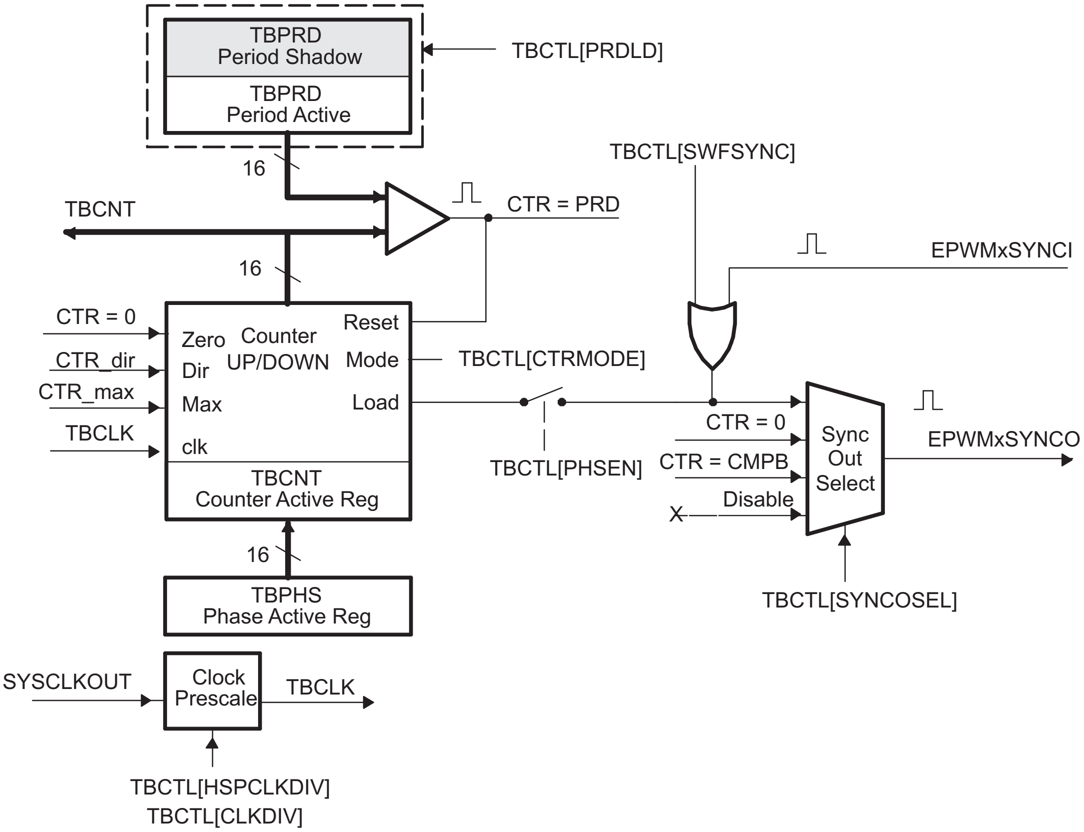


Table 20-12. Key Time-Base Signals

Signal	Description
EPWMxSYNCI	Time-base synchronization input. Input pulse used to synchronize the time-base counter with the counter of ePWM module earlier in the synchronization chain. An ePWM peripheral can be configured to use or ignore this signal. For example, this signal could come from a device pin for the first ePWM module (ePWM0). For subsequent ePWM modules this signal could be passed from another ePWM peripheral, such that EPWM1SYNCI is generated by the ePWM0 peripheral, EPWM2SYNCI is generated by ePWM1, and so forth. See Section 20.1.2 for information on the synchronization order of a particular device.
EPWMxSYNCO	Time-base synchronization output. This output pulse is used to synchronize the counter of an ePWM module later in the synchronization chain. The ePWM module generates this signal from one of three event sources: 1. EPWMxSYNCI (Synchronization input pulse) 2. CTR = 0: The time-base counter equal to zero (TBCNT = 0000h). 3. CTR = CMPB: The time-base counter equal to the counter-compare B (TBCNT = CMPB) register.
CTR = PRD	Time-base counter equal to the specified period. This signal is generated whenever the counter value is equal to the active period register value. That is when TBCNT = TBPRD.
CTR = 0	Time-base counter equal to zero. This signal is generated whenever the counter value is zero. That is when TBCNT equals 0000h.
CTR = CMPB	Time-base counter equal to active counter-compare B register (TBCNT = CMPB). This event is generated by the counter-compare submodule and used by the synchronization out logic.
CTR_dir	Time-base counter direction. Indicates the current direction of the ePWM's time-base counter. This signal is high when the counter is increasing and low when it is decreasing.
CTR_max	Time-base counter equal max value. (TBCNT = FFFFh) Generated event when the TBCNT value reaches its maximum value. This signal is only used only as a status bit.
TBCLK	Time-base clock. This is a prescaled version of the system clock (SYSCLKOUT) and is used by all submodules within the ePWM. This clock determines the rate at which time-base counter increments or decrements.

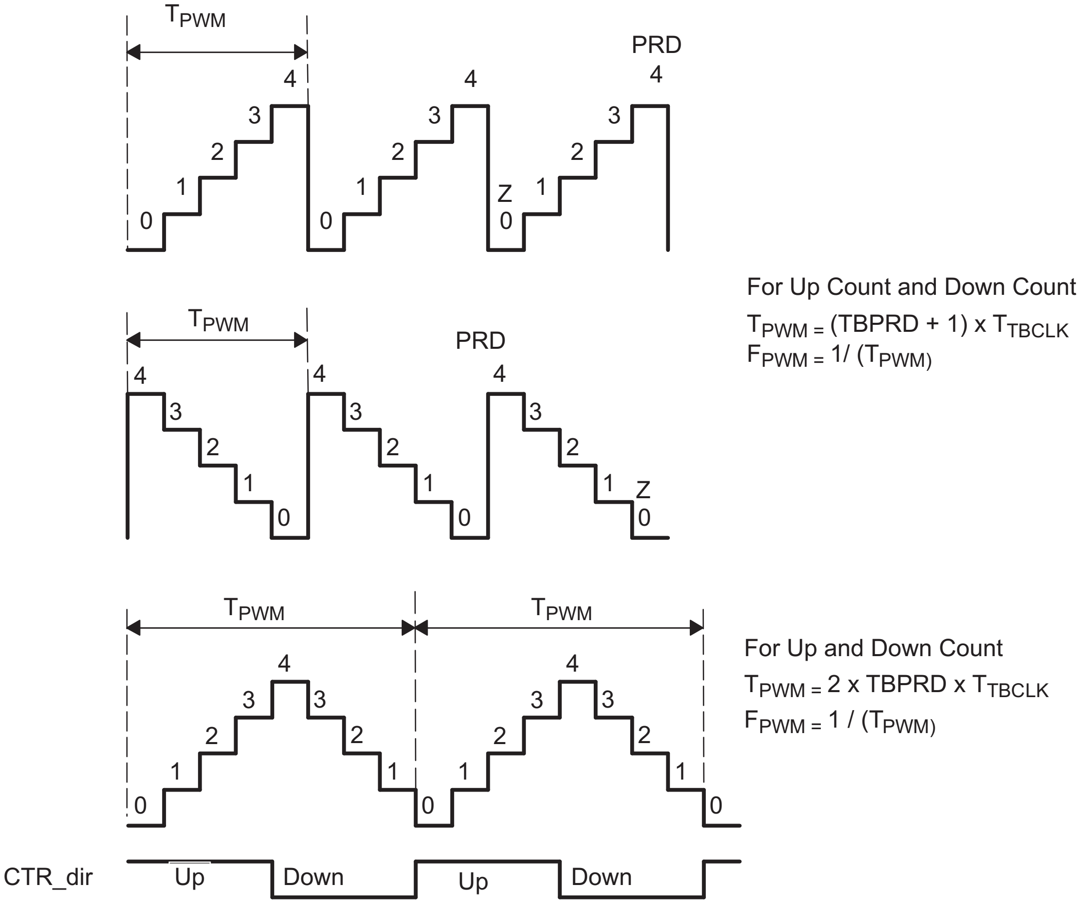
20.2.2.3.3 Calculating PWM Period and Frequency

The frequency of PWM events is controlled by the time-base period (TBPRD) register and the mode of the time-base counter. Figure 20-12 shows the period (T_{pwm}) and frequency (F_{pwm}) relationships for the up-count, down-count, and up-down-count time-base counter modes when when the period is set to 4 (TBPRD = 4). The time increment for each step is defined by the time-base clock (TBCLK) which is a prescaled version of the system clock (SYSCLKOUT).

The time-base counter has three modes of operation selected by the time-base control register (TBCTL):

- **Up-Down-Count Mode:** In up-down-count mode, the time-base counter starts from zero and increments until the period (TBPRD) value is reached. When the period value is reached, the time-base counter then decrements until it reaches zero. At this point the counter repeats the pattern and begins to increment.
- **Up-Count Mode:** In this mode, the time-base counter starts from zero and increments until it reaches the value in the period register (TBPRD). When the period value is reached, the time-base counter resets to zero and begins to increment once again.
- **Down-Count Mode:** In down-count mode, the time-base counter starts from the period (TBPRD) value and decrements until it reaches zero. When it reaches zero, the time-base counter is reset to the period value and it begins to decrement once again.

Figure 20-12. Time-Base Frequency and Period



For Up Count and Down Count

$T_{PWM} = (TBPRD + 1) \times T_{TBCLK}$

$F_{PWM} = 1/(T_{PWM})$

For Up and Down Count

$T_{PWM} = 2 \times TBPRD \times T_{TBCLK}$

$F_{PWM} = 1/(T_{PWM})$

20.2.2.3.3.1 Time-Base Period Shadow Register

The time-base period register (TBPRD) has a shadow register. Shadowing allows the register update to be synchronized with the hardware. The following definitions are used to describe all shadow registers in the ePWM module:

- **Active Register:** The active register controls the hardware and is responsible for actions that the hardware causes or invokes.
- **Shadow Register:** The shadow register buffers or provides a temporary holding location for the active register. It has no direct effect on any control hardware. At a strategic point in time the shadow register's content is transferred to the active register. This prevents corruption or spurious operation due to the register being asynchronously modified by software.

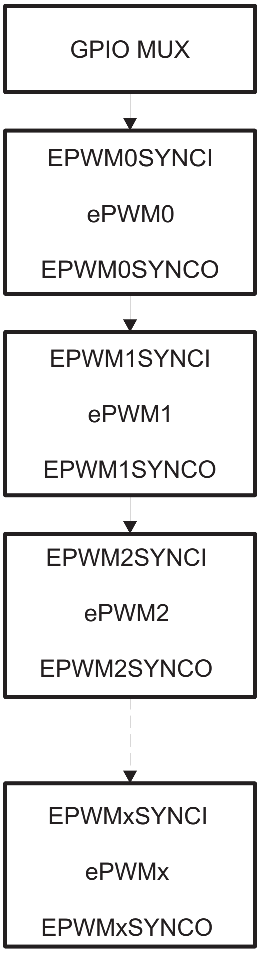
The memory address of the shadow period register is the same as the active register. Which register is written to or read from is determined by the TBCTL[PRDLD] bit. This bit enables and disables the TBPRD shadow register as follows:

- **Time-Base Period Shadow Mode:** The TBPRD shadow register is enabled when TBCTL[PRDLD] = 0. Reads from and writes to the TBPRD memory address go to the shadow register. The shadow register contents are transferred to the active register (TBPRD (Active) ← TBPRD (shadow)) when the time-base counter equals zero (TBCNT = 0000h). By default the TBPRD shadow register is enabled.
- **Time-Base Period Immediate Load Mode:** If immediate load mode is selected (TBCTL[PRDLD] = 1), then a read from or a write to the TBPRD memory address goes directly to the active register.

20.2.2.3.3.2 Time-Base Counter Synchronization

A time-base synchronization scheme connects all of the ePWM modules on a device. Each ePWM module has a synchronization input (EPWMxSYNCI) and a synchronization output (EPWMxSYNCO). The synchronization input can come from an external pin or another ePWM module. An example of synchronization connections for the remaining ePWM modules is shown in Section 20.1.2.

Figure 20-13. Time-Base Counter Synchronization Scheme 1



Each ePWM module can be configured to use or ignore the synchronization input. If the TBCTL[PHSEN] bit is set, then the time-base counter (TBCNT) of the ePWM module will be automatically loaded with the phase register (TBPHS) contents when one of the following conditions occur:

- **EPWMxSYNCI: Synchronization Input Pulse:** The value of the phase register is loaded into the counter register when an input synchronization pulse is detected (TBPHS → TBCNT). This operation occurs on the next valid time-base clock (TBCLK) edge.
- **Software Forced Synchronization Pulse:** Writing a 1 to the TBCTL[SWFSYNC] control bit invokes a software forced synchronization. This pulse is ORed with the synchronization input signal, and therefore has the same effect as a pulse on EPWMxSYNCI.

This feature enables the ePWM module to be automatically synchronized to the time base of another ePWM module. Lead or lag phase control can be added to the waveforms generated by different ePWM modules to synchronize them. In up-down-count mode, the TBCTL[PSHDIR] bit configures the direction of the time-base counter immediately after a synchronization event. The new direction is independent of the direction prior to the synchronization event. The TBPHS bit is ignored in count-up or count-down modes. See Figure 20-14 through Figure 20-17 for examples.

Clearing the TBCTL[PHSEN] bit configures the ePWM to ignore the synchronization input pulse. The synchronization pulse can still be allowed to flow-through to the EPWMxSYNCO and be used to synchronize other ePWM modules. In this way, you can set up a master time-base (for example, ePWM0) and downstream modules (ePWM1 – ePWMx) may elect to run in synchronization with the master.

20.2.2.3.4 Phase Locking the Time-Base Clocks of Multiple ePWM Modules

The TBCLKEN bit in the PWMSS_CTRL register in the Control Module can be used to globally synchronize the time-base clocks of all enabled ePWM modules on a device. The TBCLKEN bit is part of the chip configuration registers and is described in Chapter 7. When TBCLKEN = 0, the time-base clock of all ePWM modules is stopped (default). When TBCLKEN = 1, all ePWM time-base clocks are started with the rising edge of TBCLK aligned. For perfectly synchronized TBCLKs, the prescaler bits in the TBCTL register of each ePWM module must be set identically. The proper procedure for enabling the ePWM clocks is as follows:

1. Enable the ePWM module clocks.
2. Set TBCLKEN = 0. This will stop the time-base clock within any enabled ePWM module.
3. Configure the prescaler values and desired ePWM modes.
4. Set TBCLKEN = 1.

20.2.2.3.5 Time-Base Counter Modes and Timing Waveforms

The time-base counter operates in one of four modes:

- Up-count mode which is asymmetrical.
- Down-count mode which is asymmetrical.
- Up-down-count which is symmetrical.
- Frozen where the time-base counter is held constant at the current value.

To illustrate the operation of the first three modes, Figure 20-14 to Figure 20-17 show when events are generated and how the time-base responds to an EPWMxSYNCI signal.

Figure 20-14. Time-Base Up-Count Mode Waveforms

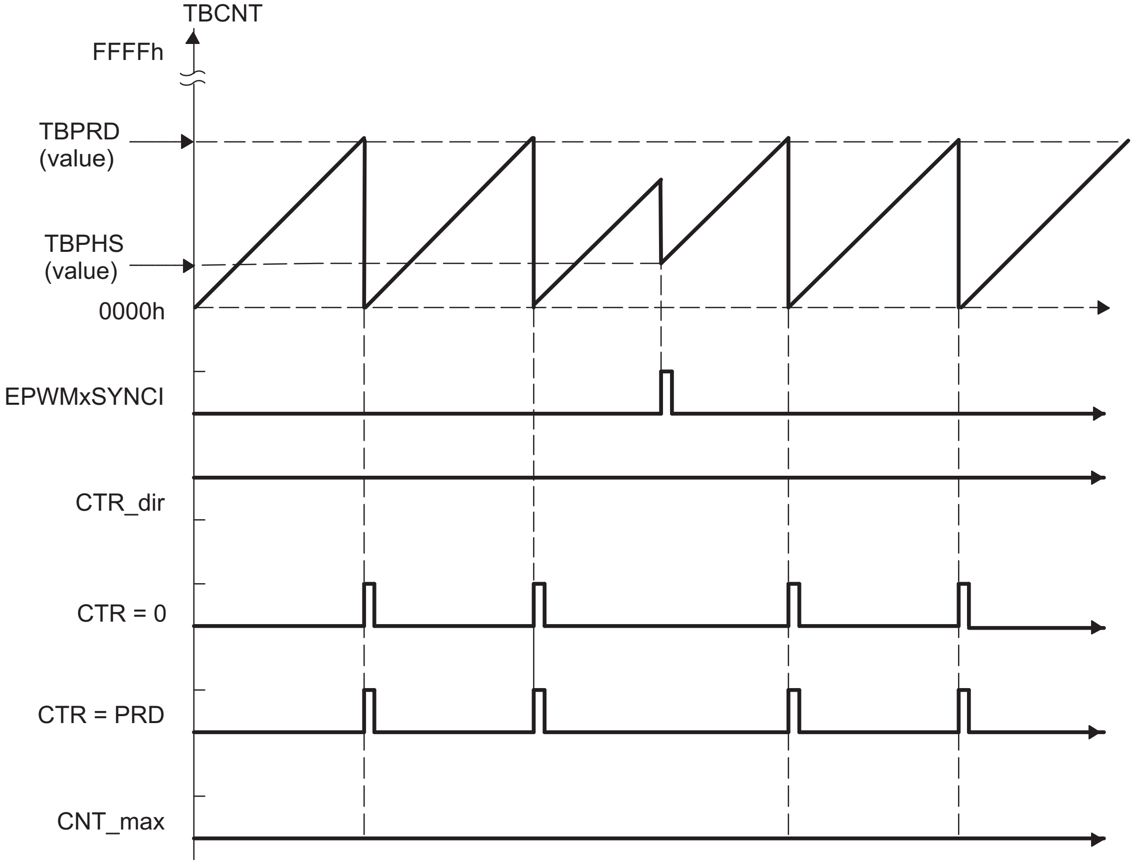


Figure 20-15. Time-Base Down-Count Mode Waveforms

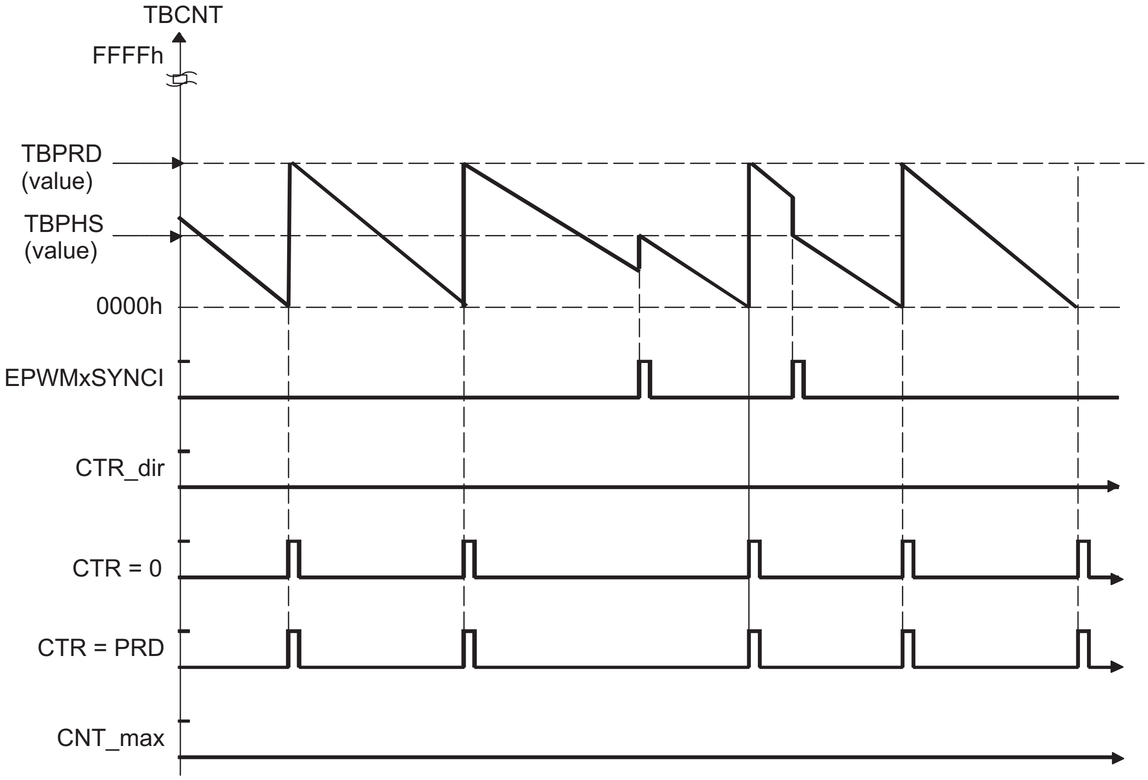

Figure 20-16. Time-Base Up-Down-Count Waveforms, TBCTL[PHSDIR = 0] Count Down on Synchronization Event

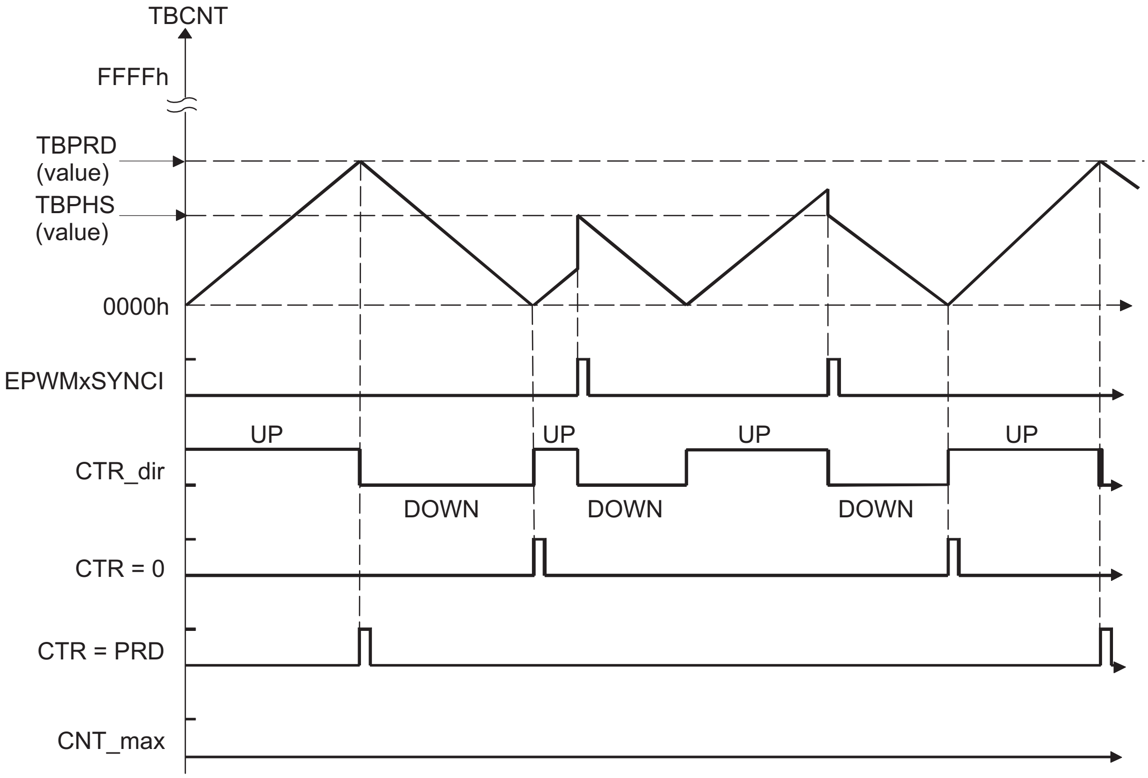

Figure 20-17. Time-Base Up-Down Count Waveforms, TBCTL[PHSDIR = 1] Count Up on Synchronization Event

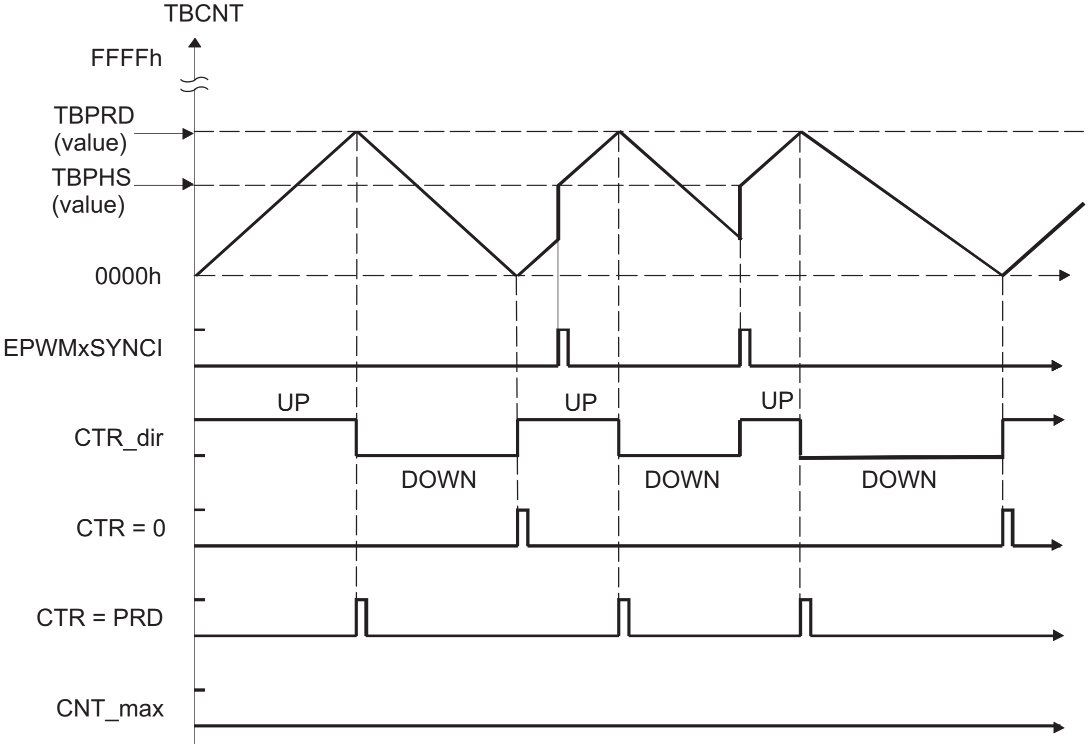

20.2.2.4 Counter-Compare (CC) Submodule

Figure 20-18 illustrates the counter-compare submodule within the ePWM. Figure 20-19 shows the basic structure of the counter-compare submodule.

Figure 20-18. Counter-Compare Submodule

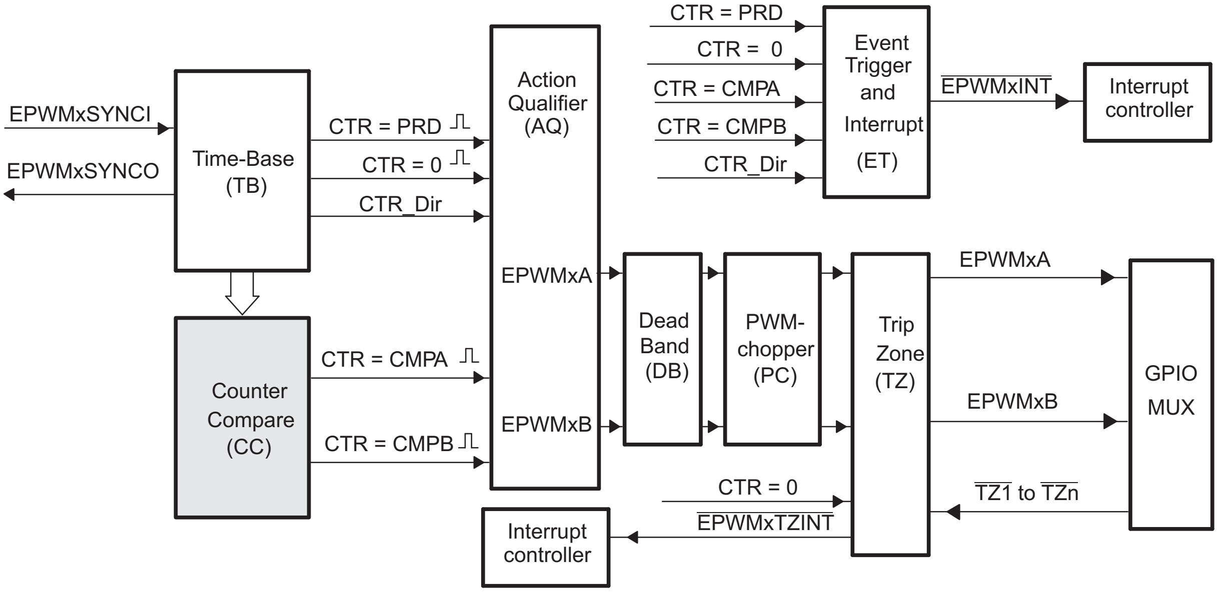

Figure 20-19. Counter-Compare Submodule Signals and Registers

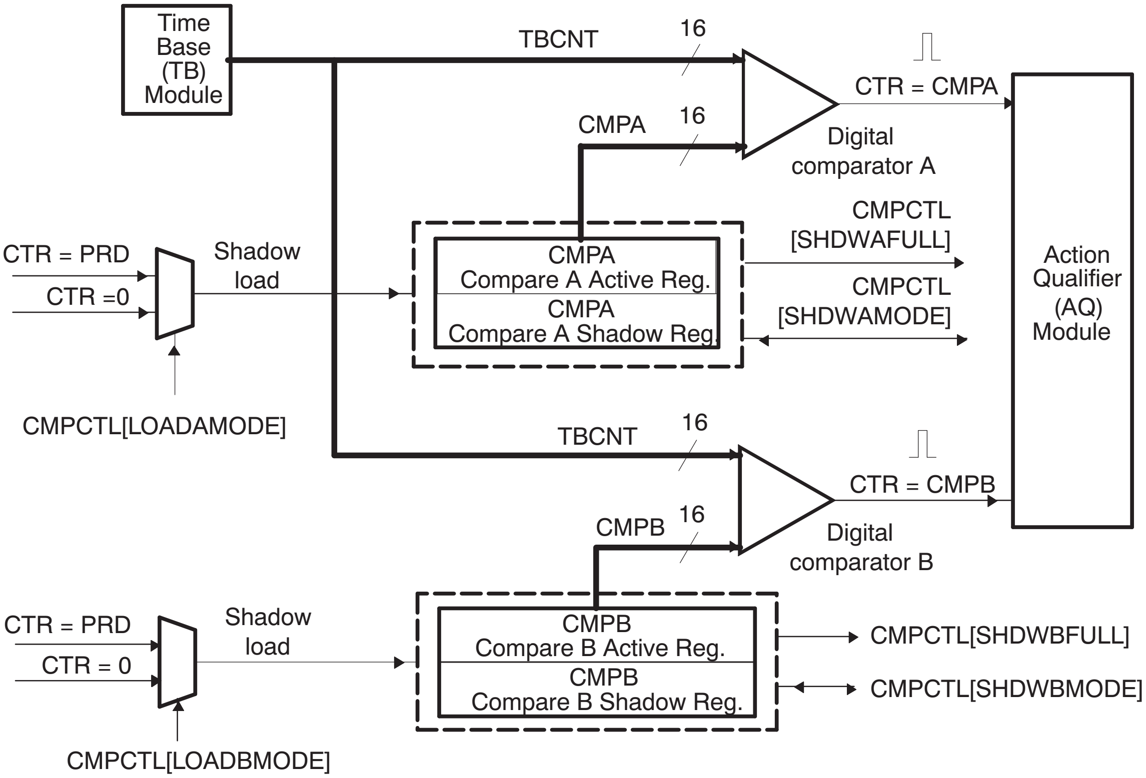


20.2.2.4.1 Purpose of the Counter-Compare Submodule

The counter-compare submodule takes as input the time-base counter value. This value is continuously compared to the counter-compare A (CMPA) and counter-compare B (CMPB) registers. When the time-base counter is equal to one of the compare registers, the counter-compare unit generates an appropriate event.

The counter-compare submodule:

- Generates events based on programmable time stamps using the CMPA and CMPB registers
  - CTR = CMPA: Time-base counter equals counter-compare A register (TBCNT = CMPA).
  - CTR = CMPB: Time-base counter equals counter-compare B register (TBCNT = CMPB)
- Controls the PWM duty cycle if the action-qualifier submodule is configured appropriately
- Shadows new compare values to prevent corruption or glitches during the active PWM cycle

20.2.2.4.2 Controlling and Monitoring the Counter-Compare Submodule

Table 20-13 lists the registers used to control and monitor the counter-compare submodule. Table 20-14 lists the key signals associated with the counter-compare submodule.

Table 20-13. Counter-Compare Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
CMPCTL	Counter-Compare Control Register.	Eh	No
CMPAHR	HRPWM Counter-Compare A Extension Register (1)	10h	Yes
CMPA	Counter-Compare A Register	12h	Yes
CMPB	Counter-Compare B Register	14h	Yes

(1) This register is available only on ePWM modules with the high-resolution extension (HRPWM). On ePWM modules that do not include the HRPWM, this location is reserved. See Section 20.1.2 to determine which ePWM instances include this feature.

Table 20-14. Counter-Compare Submodule Key Signals

Signal	Description of Event	Registers Compared
CTR = CMPA	Time-base counter equal to the active counter-compare A value	TBCNT = CMPA
CTR = CMPB	Time-base counter equal to the active counter-compare B value	TBCNT = CMPB
CTR = PRD	Time-base counter equal to the active period. Used to load active counter-compare A and B registers from the shadow register	TBCNT = TBPRD
CTR = 0	Time-base counter equal to zero. Used to load active counter-compare A and B registers from the shadow register	TBCNT = 0000h

20.2.2.4.3 Operational Highlights for the Counter-Compare Submodule

The counter-compare submodule is responsible for generating two independent compare events based on two compare registers:

1. CTR = CMPA: Time-base counter equal to counter-compare A register (TBCNT = CMPA).
2. CTR = CMPB: Time-base counter equal to counter-compare B register (TBCNT = CMPB).

For up-count or down-count mode, each event occurs only once per cycle. For up-down-count mode each event occurs twice per cycle, if the compare value is between 0000h and TBPRD; and occurs once per cycle, if the compare value is equal to 0000h or equal to TBPRD. These events are fed into the action-qualifier submodule where they are qualified by the counter direction and converted into actions if enabled. Refer to Section 20.2.2.5.1 for more details.

The counter-compare registers CMPA and CMPB each have an associated shadow register. Shadowing provides a way to keep updates to the registers synchronized with the hardware. When shadowing is used, updates to the active registers only occurs at strategic points. This prevents corruption or spurious operation due to the register being asynchronously modified by software. The memory address of the active register and the shadow register is identical. Which register is written to or read from is determined by the CMPCTL[SHDWAMODE] and CMPCTL[SHDWBMODE] bits. These bits enable and disable the CMPA shadow register and CMPB shadow register respectively. The behavior of the two load modes is described below:

- **Shadow Mode:** The shadow mode for the CMPA is enabled by clearing the CMPCTL[SHDWAMODE] bit and the shadow register for CMPB is enabled by clearing the CMPCTL[SHDWBMODE] bit. Shadow mode is enabled by default for both CMPA and CMPB.

  If the shadow register is enabled then the content of the shadow register is transferred to the active register on one of the following events:

  - CTR = PRD: Time-base counter equal to the period (TBCNT = TBPRD).
  - CTR = 0: Time-base counter equal to zero (TBCNT = 0000h)
  - Both CTR = PRD and CTR = 0

  Which of these three events is specified by the CMPCTL[LOADAMODE] and CMPCTL[LOADBMODE] register bits. Only the active register contents are used by the counter-compare submodule to generate events to be sent to the action-qualifier.
- **Immediate Load Mode:** If immediate load mode is selected (TBCTL[SHADWAMODE] = 1 or TBCTL[SHADWBMODE] = 1), then a read from or a write to the register will go directly to the active register.

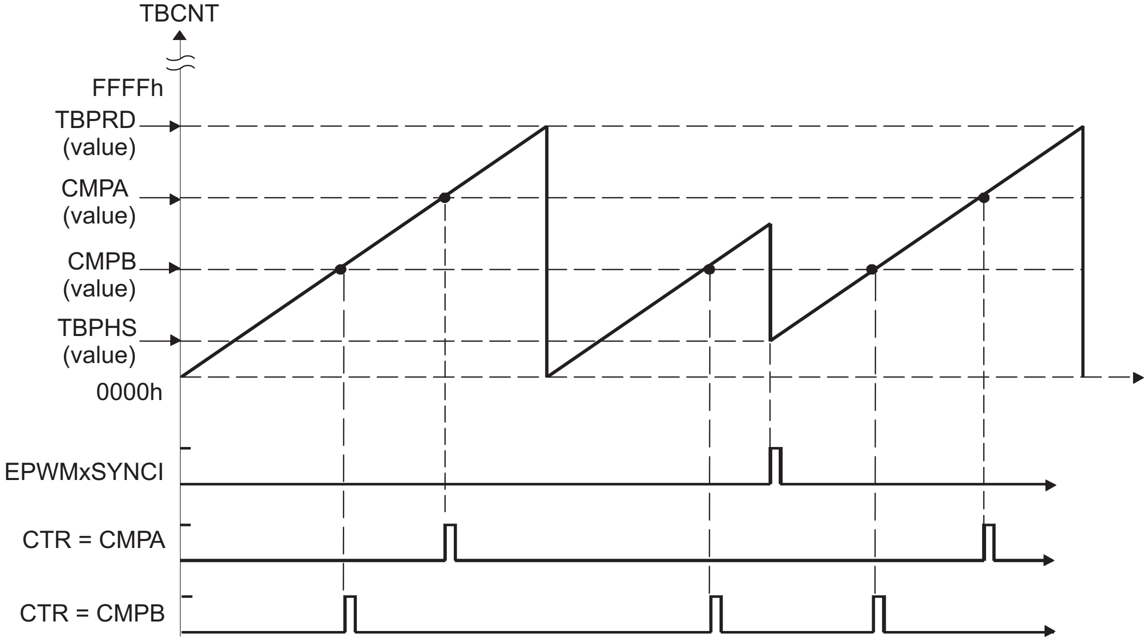
20.2.2.4.4 Count Mode Timing Waveforms

The counter-compare module can generate compare events in all three count modes:

- Up-count mode: used to generate an asymmetrical PWM waveform.
- Down-count mode: used to generate an asymmetrical PWM waveform.
- Up-down-count mode: used to generate a symmetrical PWM waveform.

To best illustrate the operation of the first three modes, the timing diagrams in Figure 20-20 to Figure 20-23 show when events are generated and how the EPWMxSYNCI signal interacts.

Figure 20-20. Counter-Compare Event Waveforms in Up-Count Mode



NOTE: An EPWMxSYNCI external synchronization event can cause a discontinuity in the TBCNT count sequence. This can lead to a compare event being skipped. This skipping is considered normal operation and must be taken into account.

Figure 20-21. Counter-Compare Events in Down-Count Mode

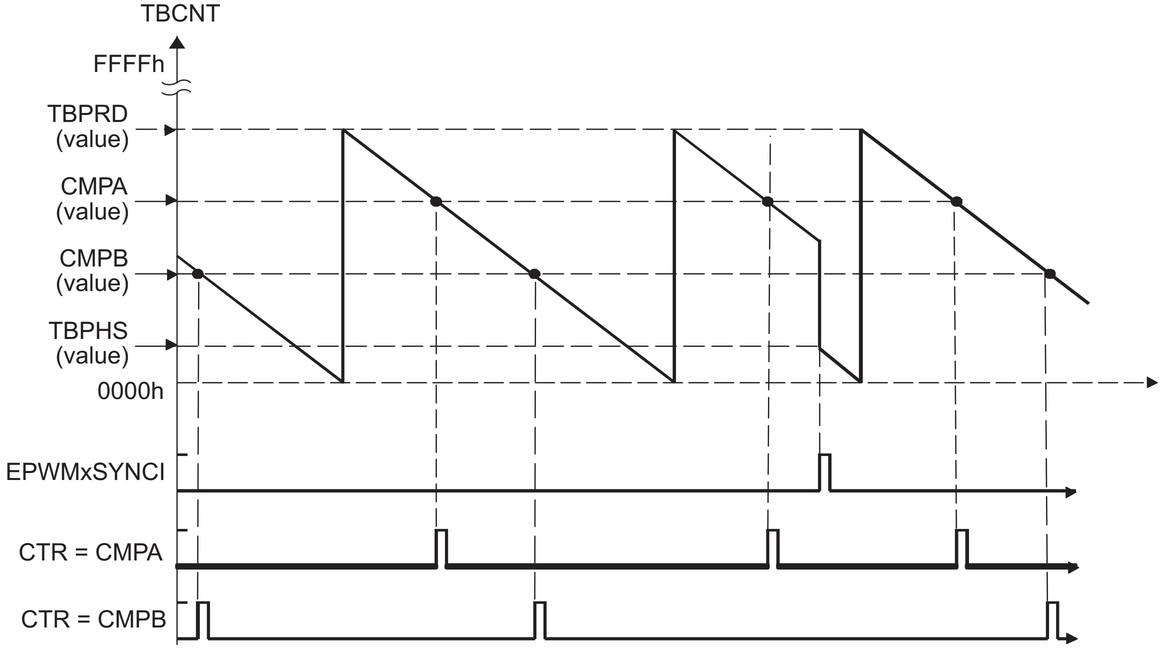


Figure 20-22. Counter-Compare Events in Up-Down-Count Mode, TBCTL[PHSDIR = 0] Count Down on Synchronization Event

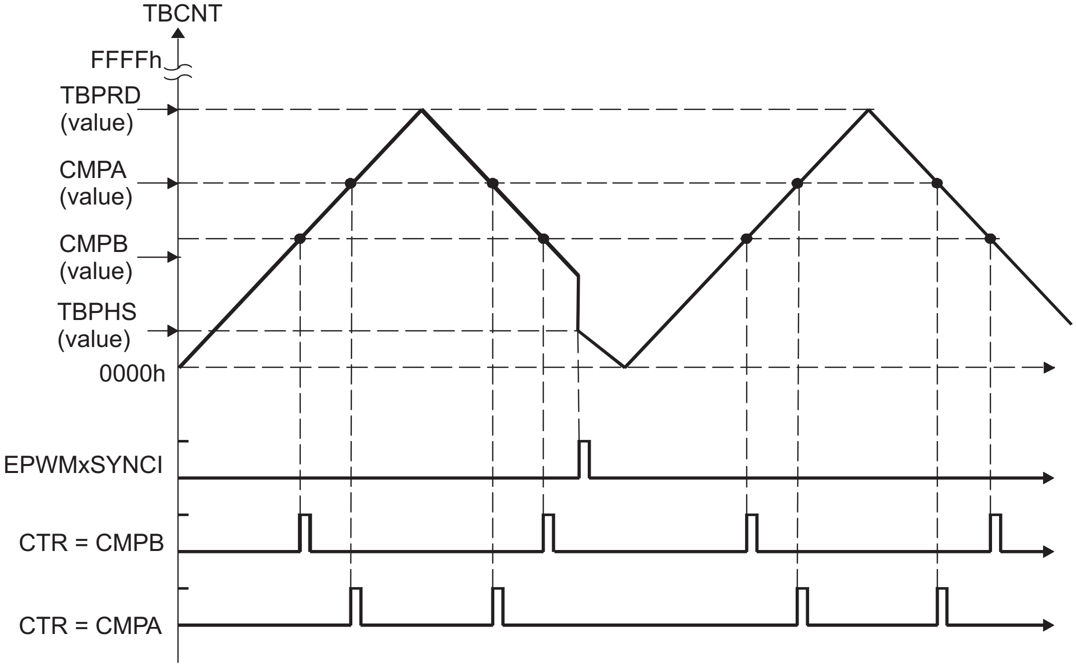

Figure 20-23. Counter-Compare Events in Up-Down-Count Mode, TBCTL[PHSDIR = 1] Count Up on Synchronization Event

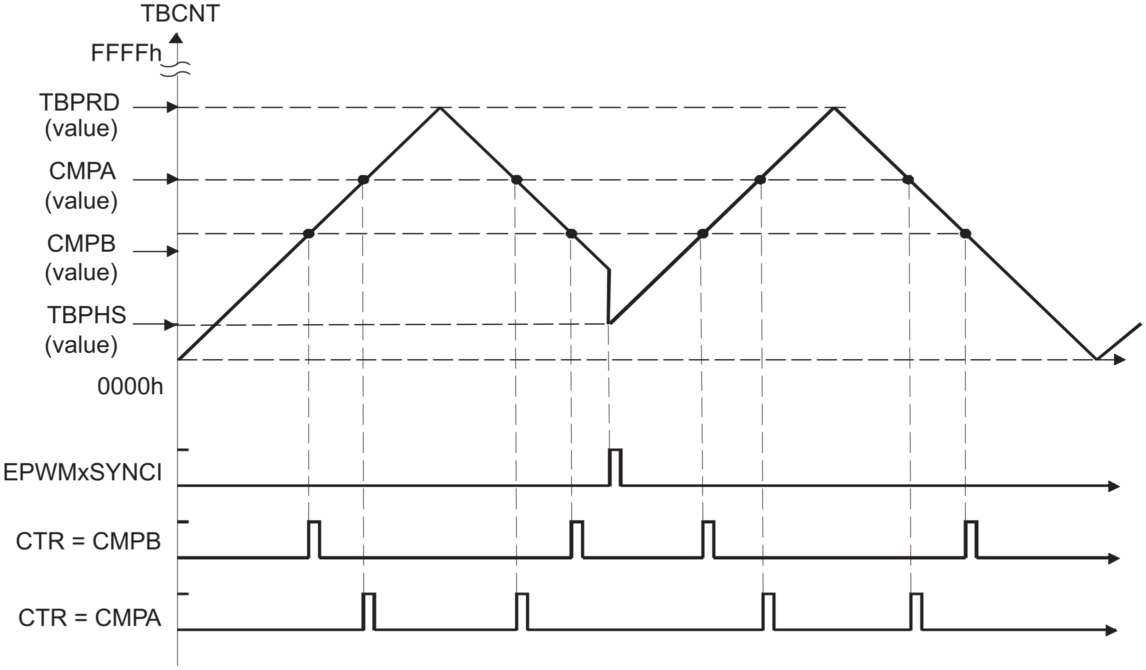
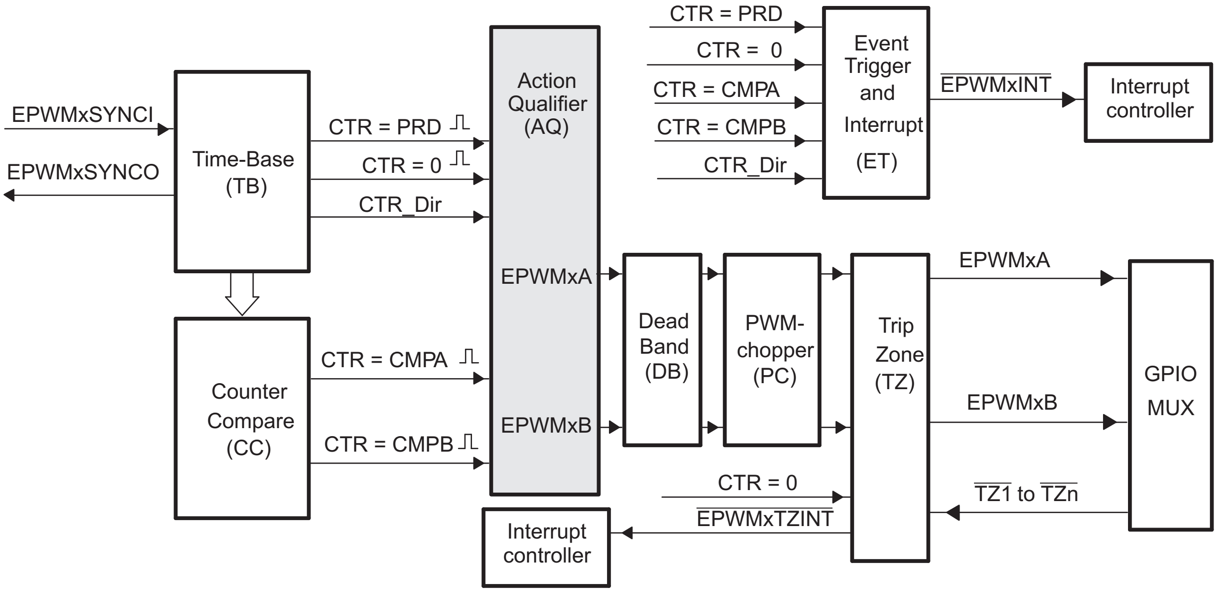


20.2.2.5 Action-Qualifier (AQ) Submodule

Figure 20-24 shows the action-qualifier (AQ) submodule (see shaded block) in the ePWM system. The action-qualifier submodule has the most important role in waveform construction and PWM generation. It decides which events are converted into various action types, thereby producing the required switched waveforms at the EPWMxA and EPWMxB outputs.

Figure 20-24. Action-Qualifier Submodule



20.2.2.5.1 *Purpose of the Action-Qualifier Submodule*

The action-qualifier submodule is responsible for the following:

- Qualifying and generating actions (set, clear, toggle) based on the following events:
  - CTR = PRD: Time-base counter equal to the period (TBCNT = TBPRD)
  - CTR = 0: Time-base counter equal to zero (TBCNT = 0000h)
  - CTR = CMPA: Time-base counter equal to the counter-compare A register (TBCNT = CMPA)
  - CTR = CMPB: Time-base counter equal to the counter-compare B register (TBCNT = CMPB)
- Managing priority when these events occur concurrently
- Providing independent control of events when the time-base counter is increasing and when it is decreasing.

20.2.2.5.2 *Controlling and Monitoring the Action-Qualifier Submodule*

Table 20-15 lists the registers used to control and monitor the action-qualifier submodule.

Table 20-15. Action-Qualifier Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
AQCTLA	Action-Qualifier Control Register For Output A (EPWMxA)	16h	No
AQCTLB	Action-Qualifier Control Register For Output B (EPWMxB)	18h	No
AQSFRC	Action-Qualifier Software Force Register	1Ah	No
AQCSFRC	Action-Qualifier Continuous Software Force	1Ch	Yes

The action-qualifier submodule is based on event-driven logic. It can be thought of as a programmable cross switch with events at the input and actions at the output, all of which are software controlled via the set of registers shown in Figure 20-25. The possible input events are summarized again in Table 20-16.

Figure 20-25. Action-Qualifier Submodule Inputs and Outputs

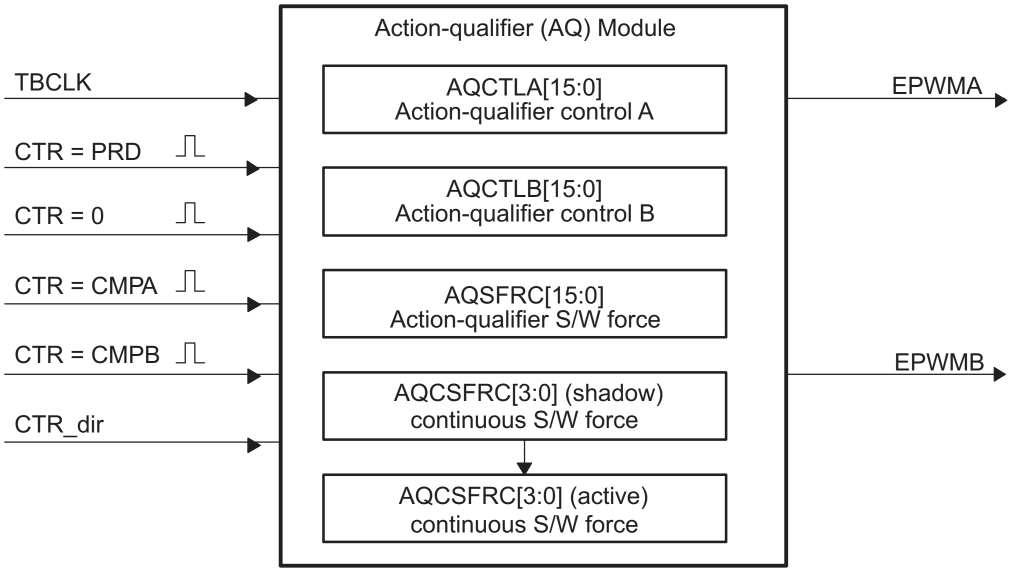


Table 20-16. Action-Qualifier Submodule Possible Input Events

Signal	Description	Registers Compared
CTR = PRD	Time-base counter equal to the period value	TBCNT = TBPRD
CTR = 0	Time-base counter equal to zero	TBCNT = 0000h
CTR = CMPA	Time-base counter equal to the counter-compare A	TBCNT = CMPA
CTR = CMPB	Time-base counter equal to the counter-compare B	TBCNT = CMPB
Software forced event	Asynchronous event initiated by software	

The software forced action is a useful asynchronous event. This control is handled by registers AQSFRC and AQCSFRC.

The action-qualifier submodule controls how the two outputs EPWMxA and EPWMxB behave when a particular event occurs. The event inputs to the action-qualifier submodule are further qualified by the counter direction (up or down). This allows for independent action on outputs on both the count-up and count-down phases.

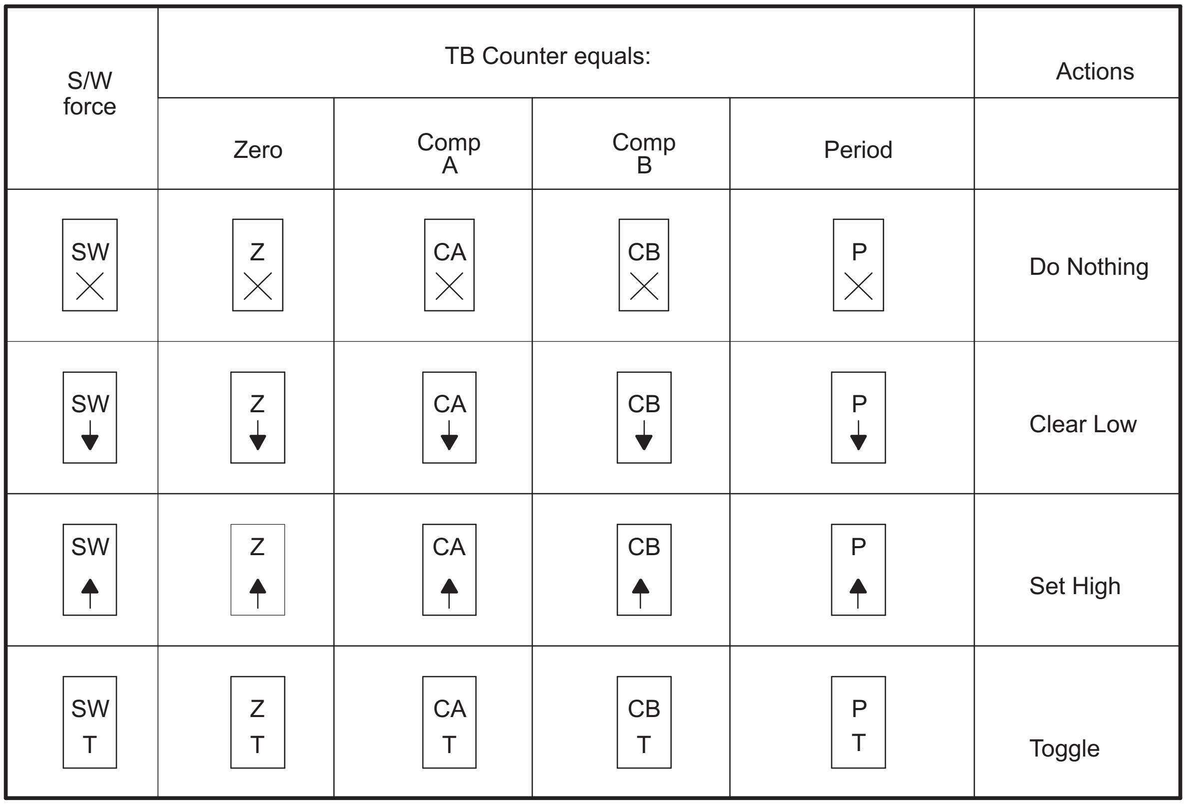
The possible actions imposed on outputs EPWMxA and EPWMxB are:

- **Set High:** Set output EPWMxA or EPWMxB to a high level.
- **Clear Low:** Set output EPWMxA or EPWMxB to a low level.
- **Toggle:** If EPWMxA or EPWMxB is currently pulled high, then pull the output low. If EPWMxA or EPWMxB is currently pulled low, then pull the output high.
- **Do Nothing:** Keep outputs EPWMxA and EPWMxB at same level as currently set. Although the "Do Nothing" option prevents an event from causing an action on the EPWMxA and EPWMxB outputs, this event can still trigger interrupts. See the event-trigger submodule description in Section 20.2.2.9 for details.

Actions are specified independently for either output (EPWMxA or EPWMxB). Any or all events can be configured to generate actions on a given output. For example, both CTR = CMPA and CTR = CMPB can operate on output EPWMxA. All qualifier actions are configured via the control registers found at the end of this section.

For clarity, the drawings in this chapter use a set of symbolic actions. These symbols are summarized in Figure 20-26. Each symbol represents an action as a marker in time. Some actions are fixed in time (zero and period) while the CMPA and CMPB actions are moveable and their time positions are programmed via the counter-compare A and B registers, respectively. To turn off or disable an action, use the "Do Nothing option"; it is the default at reset.

Figure 20-26. Possible Action-Qualifier Actions for EPWMxA and EPWMxB Outputs



S/W force	TB Counter equals:				Actions
	Zero	Comp A	Comp B	Period	
SW ×	Z ×	CA ×	CB ×	P ×	Do Nothing
SW ↓	Z ↓	CA ↓	CB ↓	P ↓	Clear Low
SW ↑	Z ↑	CA ↑	CB ↑	P ↑	Set High
SW T	Z T	CA T	CB T	P T	Toggle

20.2.2.5.3 Action-Qualifier Event Priority

It is possible for the ePWM action qualifier to receive more than one event at the same time. In this case events are assigned a priority by the hardware. The general rule is events occurring later in time have a higher priority and software forced events always have the highest priority. The event priority levels for up-down-count mode are shown in Table 20-17. A priority level of 1 is the highest priority and level 7 is the lowest. The priority changes slightly depending on the direction of TBCNT.

Table 20-17. Action-Qualifier Event Priority for Up-Down-Count Mode

Priority Level	Event if TBCNT is Incrementing TBCNT = 0 up to TBCNT = TBPRD	Event if TBCNT is Decrementing TBCNT = TBPRD down to TBCNT = 1
1 (Highest)	Software forced event	Software forced event
2	Counter equals CMPB on up-count (CBU)	Counter equals CMPB on down-count (CBD)
3	Counter equals CMPA on up-count (CAU)	Counter equals CMPA on down-count (CAD)
4	Counter equals zero	Counter equals period (TBPRD)
5	Counter equals CMPB on down-count (CBD) (1)	Counter equals CMPB on up-count (CBU) (1)
6 (Lowest)	Counter equals CMPA on down-count (CAD) (1)	Counter equals CMPA on up-count (CBU) (1)

(1) To maintain symmetry for up-down-count mode, both up-events (CAU/CBU) and down-events (CAD/CBD) can be generated for TBPRD. Otherwise, up-events can occur only when the counter is incrementing and down-events can occur only when the counter is decrementing.

Table 20-18 shows the action-qualifier priority for up-count mode. In this case, the counter direction is always defined as up and thus down-count events will never be taken.

Table 20-18. Action-Qualifier Event Priority for Up-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to period (TBPRD)
3	Counter equal to CMPB on up-count (CBU)
4	Counter equal to CMPA on up-count (CAU)
5 (Lowest)	Counter equal to Zero

Table 20-19 shows the action-qualifier priority for down-count mode. In this case, the counter direction is always defined as down and thus up-count events will never be taken.

Table 20-19. Action-Qualifier Event Priority for Down-Count Mode

Priority Level	Event
1 (Highest)	Software forced event
2	Counter equal to Zero
3	Counter equal to CMPB on down-count (CBD)
4	Counter equal to CMPA on down-count (CAD)
5 (Lowest)	Counter equal to period (TBPRD)

It is possible to set the compare value greater than the period. In this case the action will take place as shown in Table 20-20.

Table 20-20. Behavior if CMPA/CMPB is Greater than the Period

Counter Mode	Compare on Up-Count Event CAU/CBU	Compare on Down-Count Event CAU/CBU
Up-Count Mode	If CMPA/CMPB ≤ TBPRD period, then the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB > TBPRD, then the event will not occur.	Never occurs.
Down-Count Mode	Never occurs.	If CMPA/CMPB < TBPRD, the event will occur on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB ≥ TBPRD, the event will occur on a period match (TBCNT = TBPRD).
Up-Down-Count Mode	If CMPA/CMPB < TBPRD and the counter is incrementing, the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB is ≥ TBPRD, the event will occur on a period match (TBCNT = TBPRD).	If CMPA/CMPB < TBPRD and the counter is decrementing, the event occurs on a compare match (TBCNT = CMPA or CMPB). If CMPA/CMPB ≥ TBPRD, the event occurs on a period match (TBCNT = TBPRD).

20.2.2.5.4 Waveforms for Common Configurations

NOTE: The waveforms in this chapter show the ePWMs behavior for a static compare register value. In a running system, the active compare registers (CMPA and CMPB) are typically updated from their respective shadow registers once every period. The user specifies when the update will take place; either when the time-base counter reaches zero or when the time-base counter reaches period. There are some cases when the action based on the new value can be delayed by one period or the action based on the old value can take effect for an extra period. Some PWM configurations avoid this situation. These include, but are not limited to, the following:

Use up-down-count mode to generate a symmetric PWM:

- If you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1.
- If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD - 1. This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Use up-down-count mode to generate an asymmetric PWM:

- To achieve 50%-0% asymmetric PWM use the following configuration: Load CMPA/CMPB on period and use the period action to clear the PWM and a compare-up action to set the PWM. Modulate the compare value from 0 to TBPRD to achieve 50%-0% PWM duty.

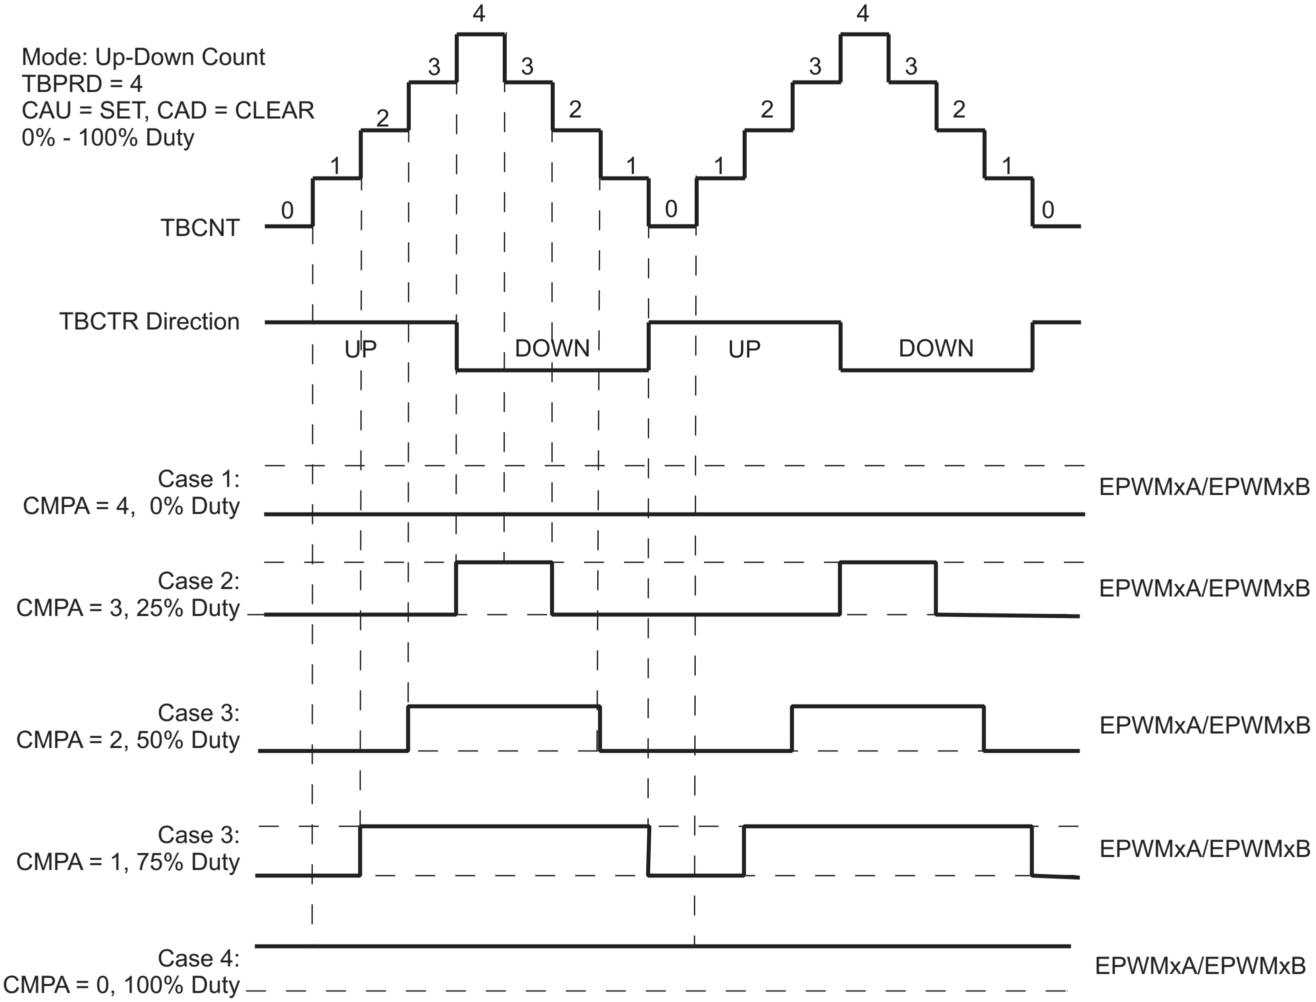
When using up-count mode to generate an asymmetric PWM:

- To achieve 0-100% asymmetric PWM use the following configuration: Load CMPA/CMPB on TBPRD. Use the Zero action to set the PWM and a compare-up action to clear the PWM. Modulate the compare value from 0 to TBPRD+1 to achieve 0-100% PWM duty.

Figure 20-27 shows how a symmetric PWM waveform can be generated using the up-down-count mode of the TBCNT. In this mode 0%-100% DC modulation is achieved by using equal compare matches on the up count and down count portions of the waveform. In the example shown, CMPA is used to make the comparison. When the counter is incrementing the CMPA match will pull the PWM output high. Likewise, when the counter is decrementing the compare match will pull the PWM signal low. When CMPA = 0, the PWM signal is low for the entire period giving the 0% duty waveform. When CMPA = TBPRD, the PWM signal is high achieving 100% duty.

When using this configuration in practice, if you load CMPA/CMPB on zero, then use CMPA/CMPB values greater than or equal to 1. If you load CMPA/CMPB on period, then use CMPA/CMPB values less than or equal to TBPRD-1. This means there will always be a pulse of at least one TBCLK cycle in a PWM period which, when very short, tend to be ignored by the system.

Figure 20-27. Up-Down-Count Mode Symmetrical Waveform

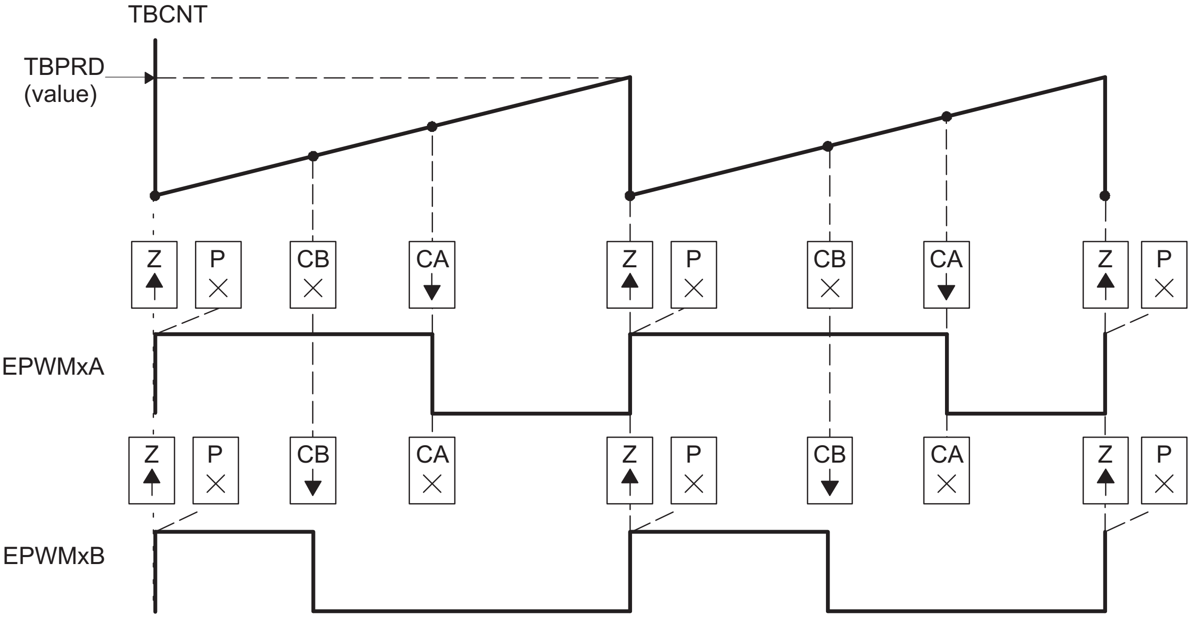


The PWM waveforms in Figure 20-28 through Figure 20-33 show some common action-qualifier configurations. Some conventions used in the figures are as follows:

- TBPRD, CMPA, and CMPB refer to the value written in their respective registers. The active register, not the shadow register, is used by the hardware.
- CMPx, refers to either CMPA or CMPB.
- EPWMxA and EPWMxB refer to the output signals from ePWMx
- Up-Down means Count-up-and-down mode, Up means up-count mode and Dwn means down-count mode
- Sym = Symmetric, Asym = Asymmetric

Table 20-21 and Table 20-22 contains initialization and runtime register configurations for the waveforms in Figure 20-28.

Figure 20-28. Up, Single Edge Asymmetric Waveform, With Independent Modulation on EPWMxA and EPWMxB—Active High



(1) PWM period = (TBPRD + 1) × T_{TBCLK}

(2) Duty modulation for EPWMxA is set by CMPA, and is active high (that is, high time duty proportional to CMPA).

(3) Duty modulation for EPWMxB is set by CMPB and is active high (that is, high time duty proportional to CMPB).

(4) The "Do Nothing" actions (X) are shown for completeness, but will not be shown on subsequent diagrams.

(5) Actions at zero and period, although appearing to occur concurrently, are actually separated by one TBCLK period. TBCNT wraps from period to 0000h.

Table 20-21. EPWMx Initialization for Figure 20-28

Register	Bit	Value	Comments
TBPRD	TBPRD	600 (258h)	Period = 601 TBCLK counts
TBPHS	TBPHS	0	Clear Phase Register to 0
TBCNT	TBCNT	0	Clear TB counter
TBCTL	CTRMODE	TB_UP	
	PHSEN	TB_DISABLE	Phase loading disabled
	PRDLD	TB_SHADOW	
	SYNCOSEL	TB_SYNC_DISABLE	
	HSPCLKDIV	TB_DIV1	TBCLK = SYSCLK
	CLKDIV	TB_DIV1	
CMPA	CMPA	350 (15Eh)	Compare A = 350 TBCLK counts
CMPB	CMPB	200 (C8h)	Compare B = 200 TBCLK counts
CMPCTL	SHDWAMODE	CC_SHADOW	
	SHDWBMODE	CC_SHADOW	
	LOADAMODE	CC_CTR_ZERO	Load on CTR = 0

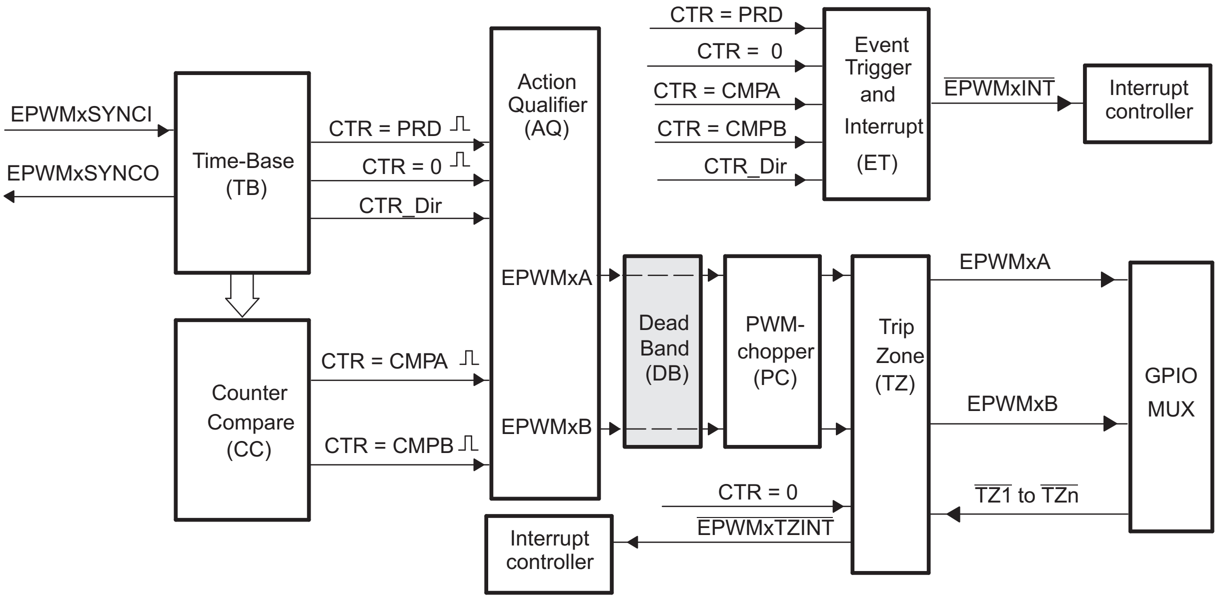
20.2.2.6 Dead-Band Generator (DB) Submodule

Figure 20-34 illustrates the dead-band generator submodule within the ePWM module.

Figure 20-34. Dead-Band Generator Submodule



20.2.2.6.1 Purpose of the Dead-Band Submodule

The "Action-qualifier (AQ) Module" section discussed how it is possible to generate the required dead-band by having full control over edge placement using both the CMPA and CMPB resources of the ePWM module. However, if the more classical edge delay-based dead-band with polarity control is required, then the dead-band generator submodule should be used.

The key functions of the dead-band generator submodule are:

- Generating appropriate signal pairs (EPWMxA and EPWMxB) with dead-band relationship from a single EPWMxA input
- Programming signal pairs for:
  - Active high (AH)
  - Active low (AL)
  - Active high complementary (AHC)
  - Active low complementary (ALC)
- Adding programmable delay to rising edges (RED)
- Adding programmable delay to falling edges (FED)
- Can be totally bypassed from the signal path (note dotted lines in diagram)

20.2.2.6.2 Controlling and Monitoring the Dead-Band Submodule

The dead-band generator submodule operation is controlled and monitored via the following registers:

Table 20-33. Dead-Band Generator Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
DBCTL	Dead-Band Control Register	1Eh	No
DBRED	Dead-Band Rising Edge Delay Count Register	20h	No
DBFED	Dead-Band Falling Edge Delay Count Register	22h	No

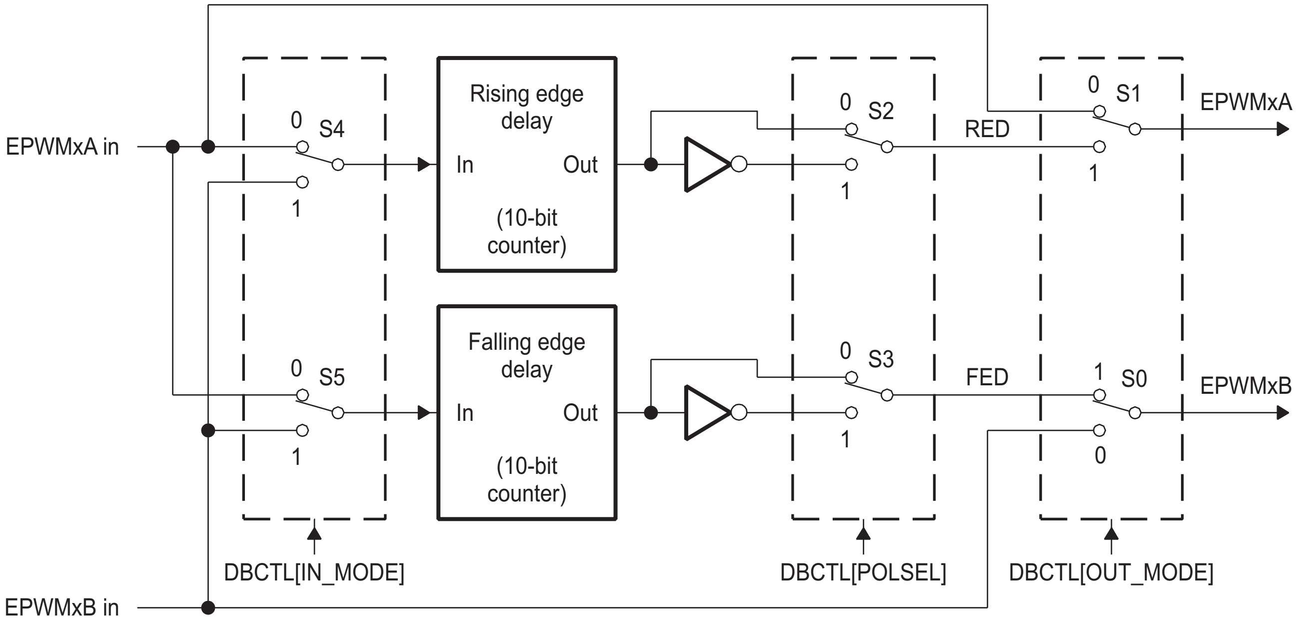
20.2.2.6.3 Operational Highlights for the Dead-Band Generator Submodule

The following sections provide the operational highlights.

The dead-band submodule has two groups of independent selection options as shown in Figure 20-35.

- **Input Source Selection:** The input signals to the dead-band module are the EPWMxA and EPWMxB output signals from the action-qualifier. In this section they will be referred to as EPWMxA In and EPWMxB In. Using the DBCTL[IN_MODE) control bits, the signal source for each delay, falling-edge or rising-edge, can be selected:
  - EPWMxA In is the source for both falling-edge and rising-edge delay. This is the default mode.
  - EPWMxA In is the source for falling-edge delay, EPWMxB In is the source for rising-edge delay.
  - EPWMxA In is the source for rising edge delay, EPWMxB In is the source for falling-edge delay.
  - EPWMxB In is the source for both falling-edge and rising-edge delay.
- **Output Mode Control:** The output mode is configured by way of the DBCTL[OUT_MODE] bits. These bits determine if the falling-edge delay, rising-edge delay, neither, or both are applied to the input signals.
- **Polarity Control:** The polarity control (DBCTL[POLSEL]) allows you to specify whether the rising-edge delayed signal and/or the falling-edge delayed signal is to be inverted before being sent out of the dead-band submodule.

Figure 20-35. Configuration Options for the Dead-Band Generator Submodule



Although all combinations are supported, not all are typical usage modes. Table 20-34 lists some classical dead-band configurations. These modes assume that the DBCTL[IN_MODE] is configured such that EPWMxA In is the source for both falling-edge and rising-edge delay. Enhanced, or non-traditional modes can be achieved by changing the input signal source. The modes shown in Table 20-34 fall into the following categories:

- **Mode 1: Bypass both falling-edge delay (FED) and rising-edge delay (RED)** Allows you to fully disable the dead-band submodule from the PWM signal path.
- **Mode 2-5: Classical Dead-Band Polarity Settings** These represent typical polarity configurations that should address all the active high/low modes required by available industry power switch gate drivers. The waveforms for these typical cases are shown in Figure 20-36. Note that to generate equivalent waveforms to Figure 20-36, configure the action-qualifier submodule to generate the signal as shown for EPWMxA.
- **Mode 6: Bypass rising-edge-delay and Mode 7: Bypass falling-edge-delay** Finally the last two entries in Table 20-34 show combinations where either the falling-edge-delay (FED) or rising-edge-delay (RED) blocks are bypassed.

Table 20-34. Classical Dead-Band Operating Modes

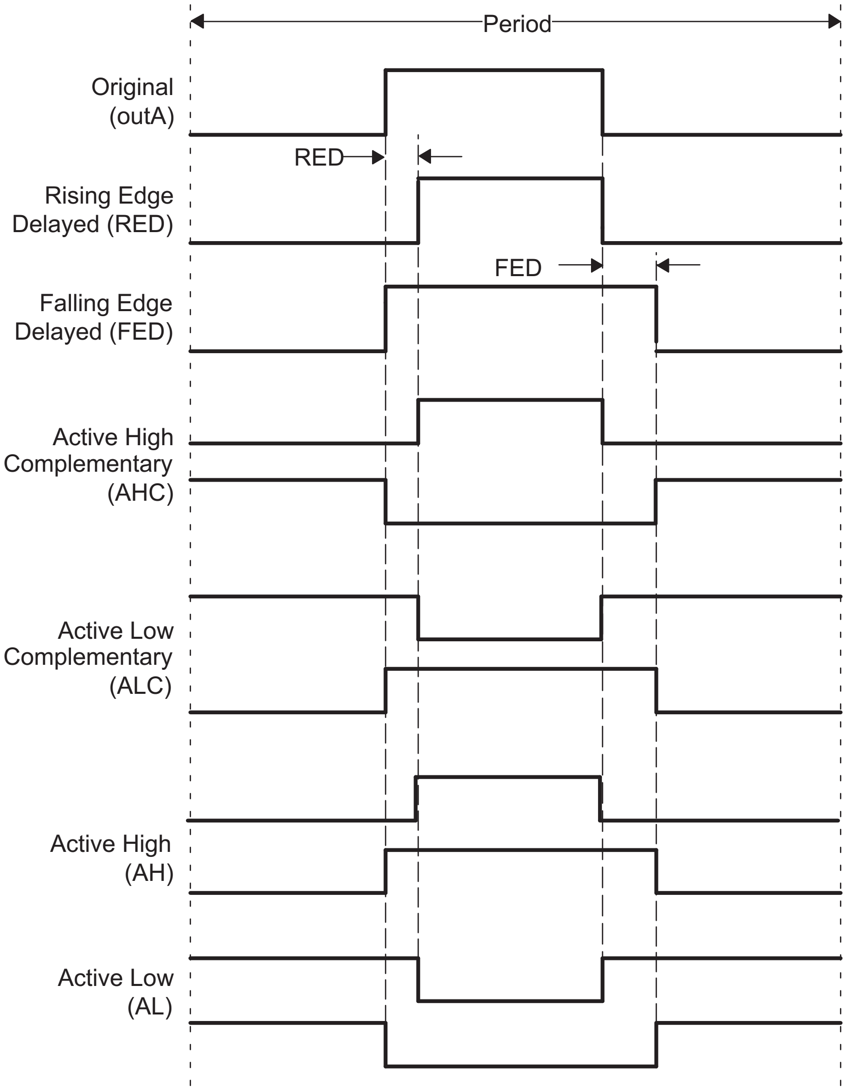
		DBCTL[POLSEL]		DBCTL[OUT_MODE]	
Mode	**Mode Description** [1]	**S3**	**S2**	**S1**	**S0**
1	EPWMxA and EPWMxB Passed Through (No Delay)	x	x	0	0
2	Active High Complementary (AHC)	1	0	1	1
3	Active Low Complementary (ALC)	0	1	1	1
4	Active High (AH)	0	0	1	1
5	Active Low (AL)	1	1	1	1
6	EPWMxA Out = EPWMxA In (No Delay) EPWMxB Out = EPWMxA In with Falling Edge Delay	0 or 1	0 or 1	0	1
7	EPWMxA Out = EPWMxA In with Rising Edge Delay EPWMxB Out = EPWMxB In with No Delay	0 or 1	0 or 1	1	0

---

[1] These are classical dead-band modes and assume that DBCTL[IN_MODE] = 0,0. That is, EPWMxA in is the source for both the falling-edge and rising-edge delays. Enhanced, non-traditional modes can be achieved by changing the IN_MODE configuration.

Figure 20-36 shows waveforms for typical cases where 0% < duty < 100%.

Figure 20-36. Dead-Band Waveforms for Typical Cases (0% < Duty < 100%)



The dead-band submodule supports independent values for rising-edge (RED) and falling-edge (FED) delays. The amount of delay is programmed using the DBRED and DBFED registers. These are 10-bit registers and their value represents the number of time-base clock, TBCLK, periods a signal edge is delayed by. For example, the formula to calculate falling-edge-delay and rising-edge-delay are:

$FED = DBFED \times T_{TBCLK}$

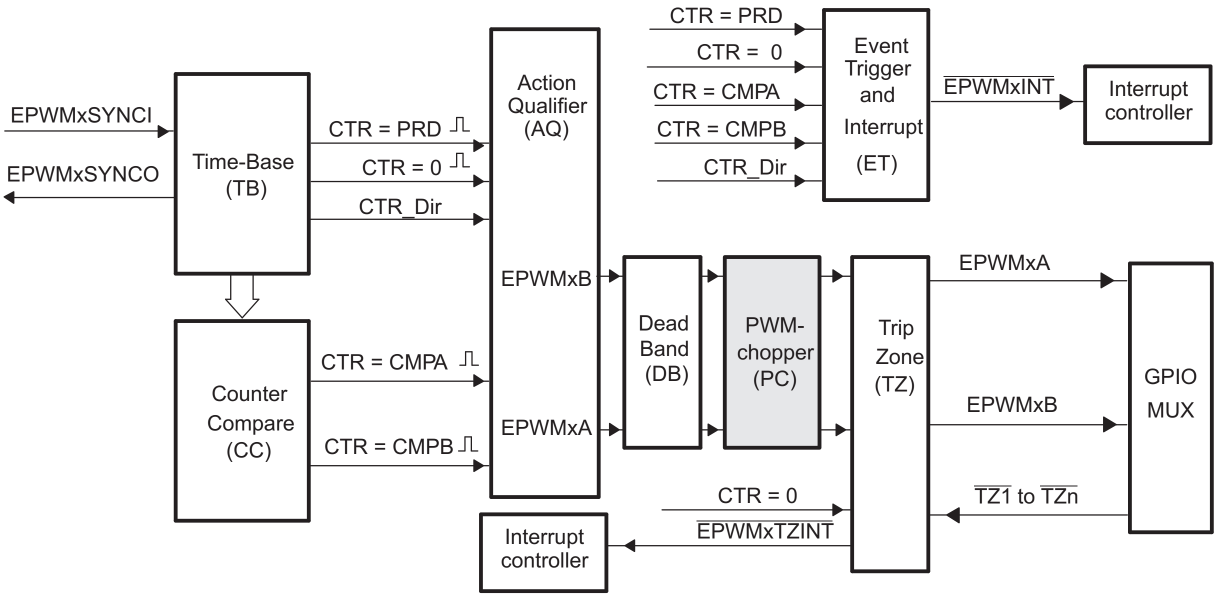
$RED = DBRED \times T_{TBCLK}$

Where T_{TBCLK} is the period of TBCLK, the prescaled version of SYSCLKOUT.

20.2.2.7 PWM-Chopper (PC) Submodule

Figure 20-37 illustrates the PWM-chopper (PC) submodule within the ePWM module. The PWM-chopper submodule allows a high-frequency carrier signal to modulate the PWM waveform generated by the action-qualifier and dead-band submodules. This capability is important if you need pulse transformer-based gate drivers to control the power switching elements.

Figure 20-37. PWM-Chopper Submodule



20.2.2.7.1 *Purpose of the PWM-Chopper Submodule*

The key functions of the PWM-chopper submodule are:

- Programmable chopping (carrier) frequency
- Programmable pulse width of first pulse
- Programmable duty cycle of second and subsequent pulses
- Can be fully bypassed if not required

20.2.2.7.2 *Controlling the PWM-Chopper Submodule*

The PWM-chopper submodule operation is controlled via the register in Table 20-35.

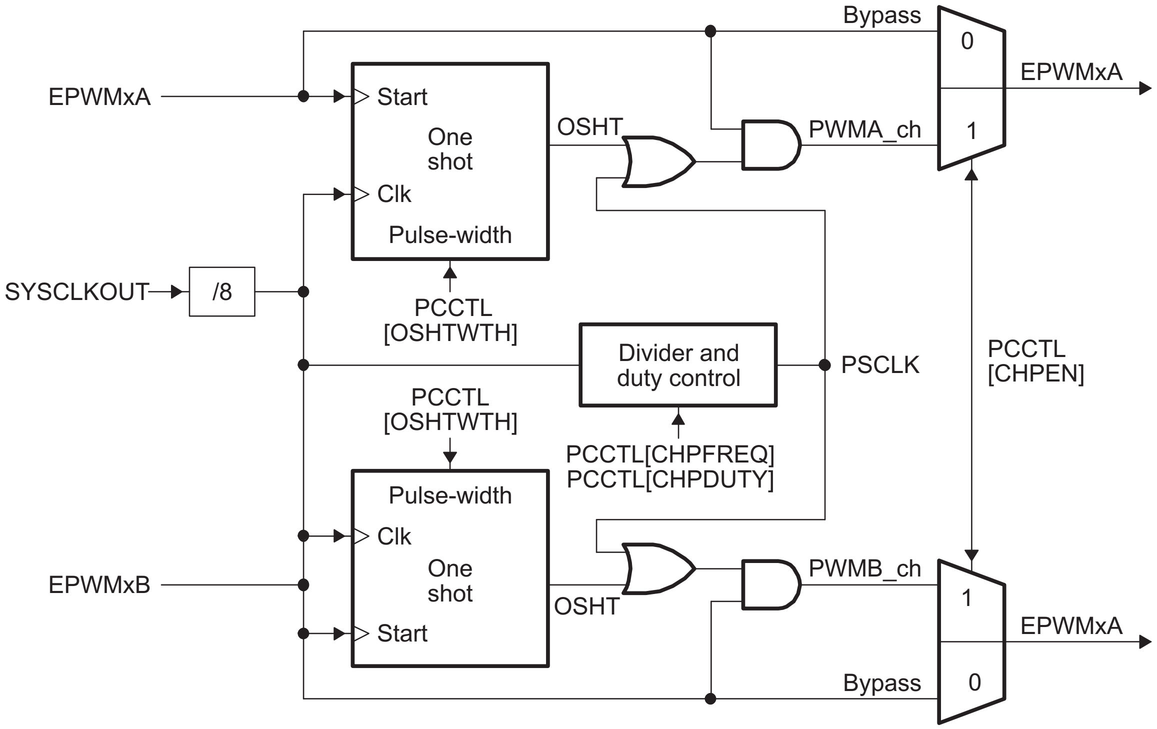
Table 20-35. PWM-Chopper Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
PCCTL	PWM-chopper Control Register	3Ch	No

20.2.2.7.3 Operational Highlights for the PWM-Chopper Submodule

Figure 20-38 shows the operational details of the PWM-chopper submodule. The carrier clock is derived from SYSCLKOUT. Its frequency and duty cycle are controlled via the CHPFREQ and CHPDUTY bits in the PCCTL register. The one-shot block is a feature that provides a high energy first pulse to ensure hard and fast power switch turn on, while the subsequent pulses sustain pulses, ensuring the power switch remains on. The one-shot width is programmed via the OSHTWTH bits. The PWM-chopper submodule can be fully disabled (bypassed) via the CHPEN bit.

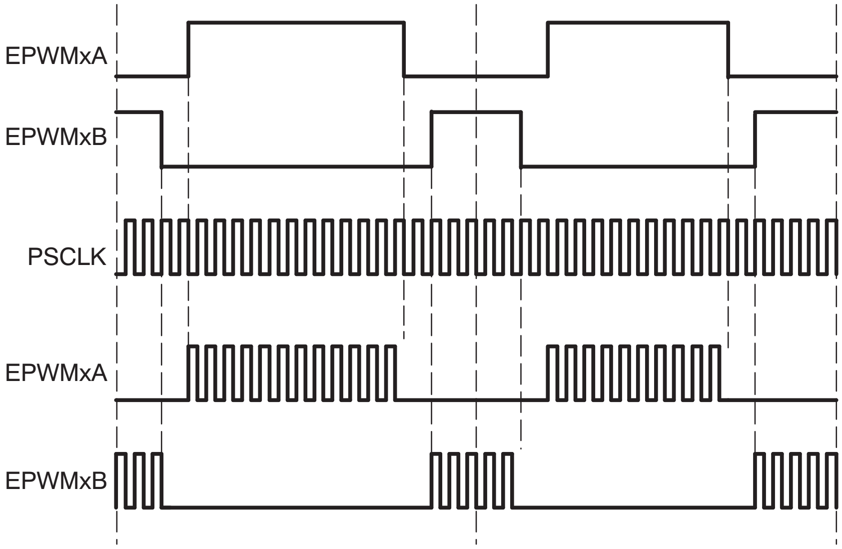
Figure 20-38. PWM-Chopper Submodule Signals and Registers



20.2.2.7.4 Waveforms

Figure 20-39 shows simplified waveforms of the chopping action only; one-shot and duty-cycle control are not shown. Details of the one-shot and duty-cycle control are discussed in the following sections.

Figure 20-39. Simple PWM-Chopper Submodule Waveforms Showing Chopping Action Only



20.2.2.7.4.1 One-Shot Pulse

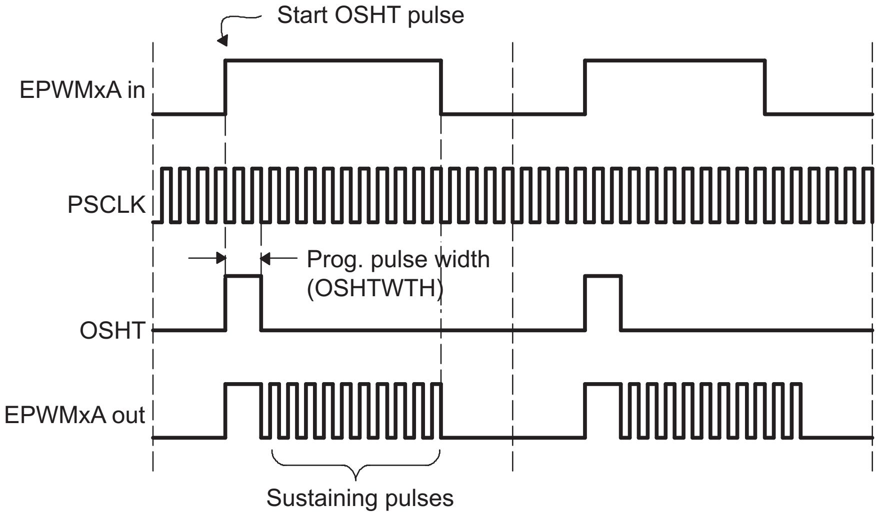
The width of the first pulse can be programmed to any of 16 possible pulse width values. The width or period of the first pulse is given by:

$$T_{1stpulse} = T_{SYSCLKOUT} \times 8 \times OSHTWTH$$

Where $T_{SYSCLKOUT}$ is the period of the system clock (SYSCLKOUT) and OSHTWTH is the four control bits (value from 1 to 16)

Figure 20-40 shows the first and subsequent sustaining pulses.

Figure 20-40. PWM-Chopper Submodule Waveforms Showing the First Pulse and Subsequent Sustaining Pulses

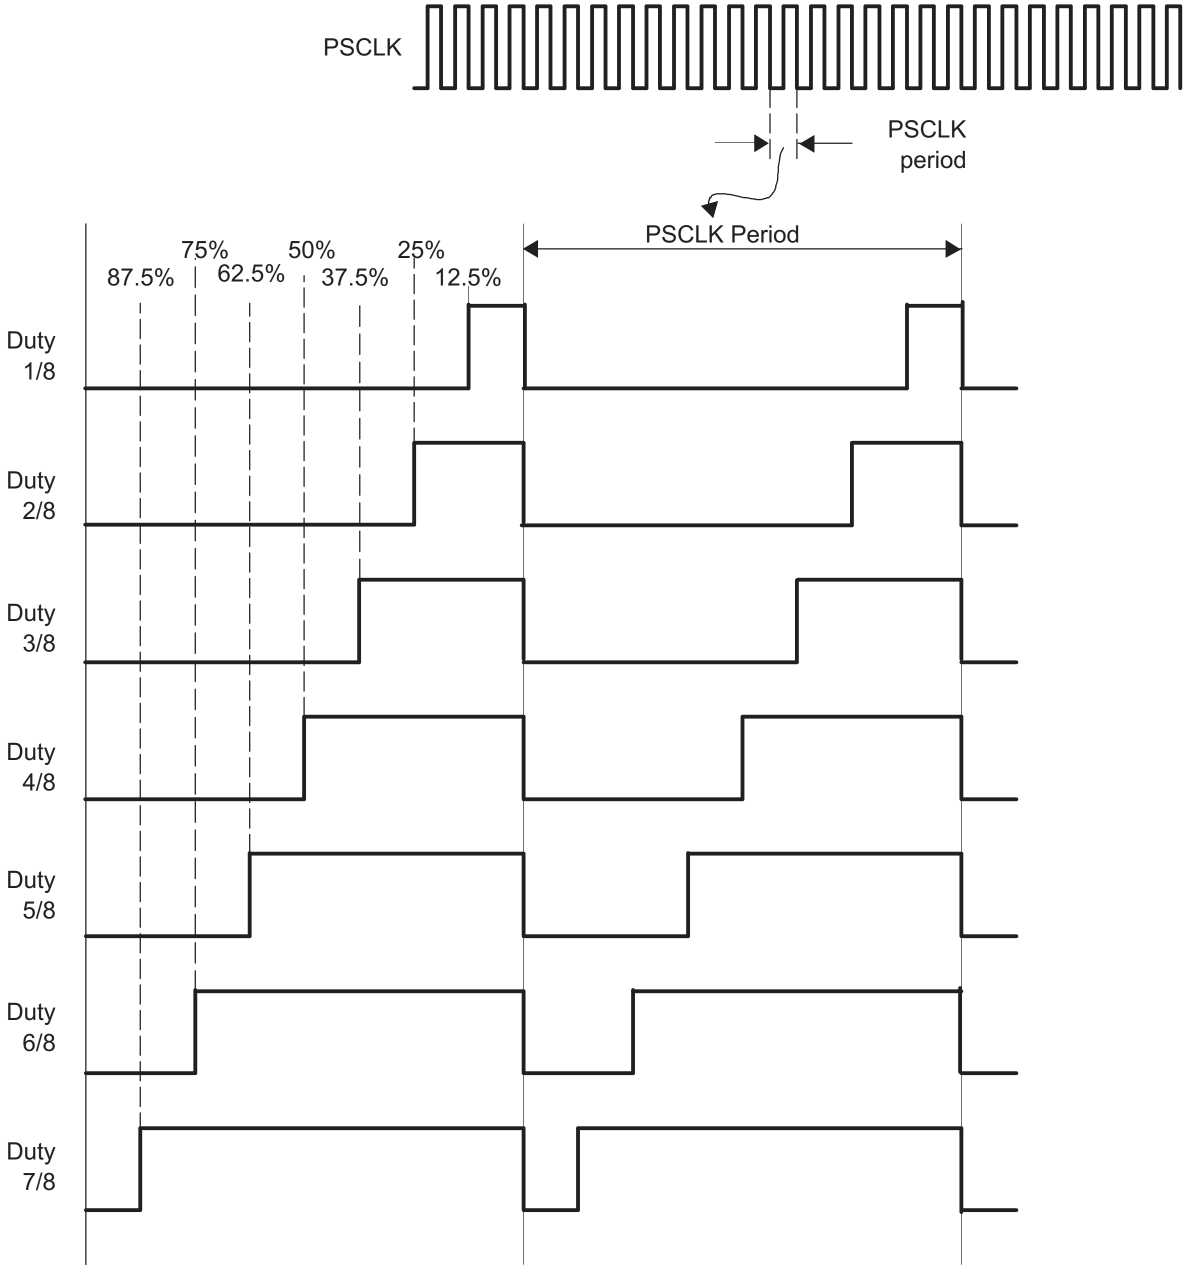


20.2.2.7.4.2 Duty Cycle Control

Pulse transformer-based gate drive designs need to comprehend the magnetic properties or characteristics of the transformer and associated circuitry. Saturation is one such consideration. To assist the gate drive designer, the duty cycles of the second and subsequent pulses have been made programmable. These sustaining pulses ensure the correct drive strength and polarity is maintained on the power switch gate during the on period, and hence a programmable duty cycle allows a design to be tuned or optimized via software control.

Figure 20-41 shows the duty cycle control that is possible by programming the CHPDUTY bits. One of seven possible duty ratios can be selected ranging from 12.5% to 87.5%.

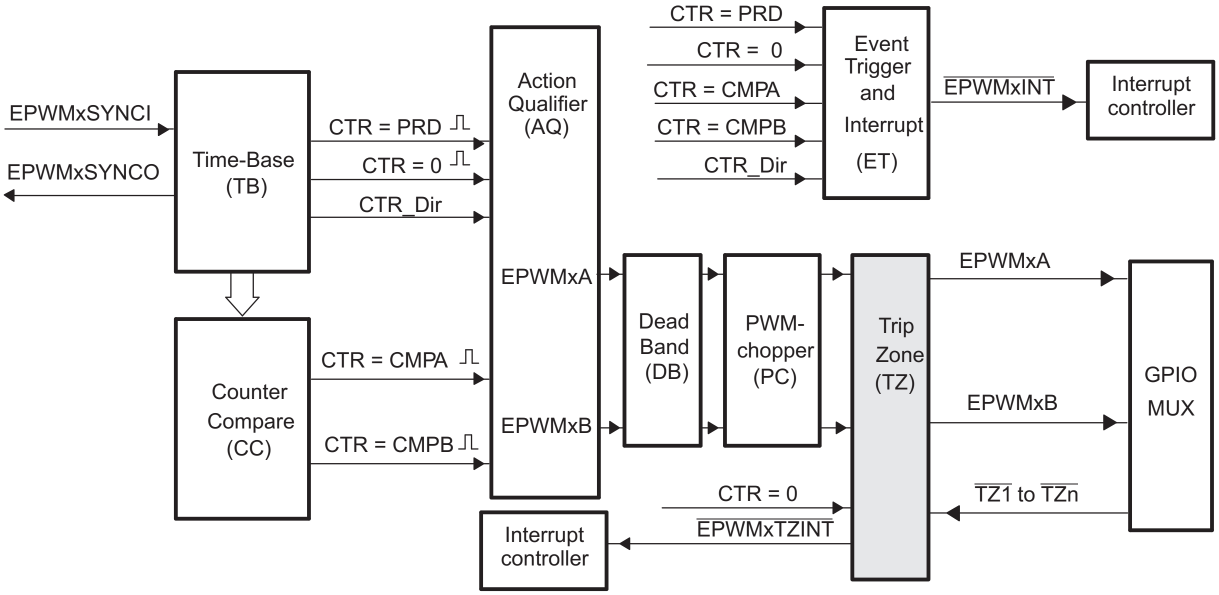
Figure 20-41. PWM-Chopper Submodule Waveforms Showing the Pulse Width (Duty Cycle) Control of Sustaining Pulses



20.2.2.8 Trip-Zone (TZ) Submodule

Figure 20-42 shows how the trip-zone (TZ) submodule fits within the ePWM module. Each ePWM module is connected to every $\overline{\text{TZ}}$ signal that are sourced from the GPIO MUX. These signals indicates external fault or trip conditions, and the ePWM outputs can be programmed to respond accordingly when faults occur. See Section 20.1.2 to determine the number of trip-zone pins available for the device.

Figure 20-42. Trip-Zone Submodule



20.2.2.8.1 *Purpose of the Trip-Zone Submodule*

The key functions of the trip-zone submodule are:

- Trip inputs $\overline{\text{TZ1}}$ to $\overline{\text{TZn}}$ can be flexibly mapped to any ePWM module.
- Upon a fault condition, outputs EPWMxA and EPWMxB can be forced to one of the following:
  - High
  - Low
  - High-impedance
  - No action taken
- Support for one-shot trip (OSHT) for major short circuits or over-current conditions.
- Support for cycle-by-cycle tripping (CBC) for current limiting operation.
- Each trip-zone input pin can be allocated to either one-shot or cycle-by-cycle operation.
- Interrupt generation is possible on any trip-zone pin.
- Software-forced tripping is also supported.
- The trip-zone submodule can be fully bypassed if it is not required.

20.2.2.8.2 Controlling and Monitoring the Trip-Zone Submodule

The trip-zone submodule operation is controlled and monitored through the following registers:

Table 20-36. Trip-Zone Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
TZSEL	Trip-Zone Select Register	24h	No
TZCTL	Trip-Zone Control Register	28h	No
TZEINT	Trip-Zone Enable Interrupt Register	2Ah	No
TZFLG	Trip-Zone Flag Register	2Ch	No
TZCLR	Trip-Zone Clear Register	2Eh	No
TZFRC	Trip-Zone Force Register	30h	No

20.2.2.8.3 Operational Highlights for the Trip-Zone Submodule

The following sections describe the operational highlights and configuration options for the trip-zone submodule.

The trip-zone signals at pin $\overline{\text{TZ1}}$ to $\overline{\text{TZn}}$ is an active-low input signal. When the pin goes low, it indicates that a trip event has occurred. Each ePWM module can be individually configured to ignore or use each of the trip-zone pins. Which trip-zone pins are used by a particular ePWM module is determined by the TZSEL register for that specific ePWM module. The trip-zone signal may or may not be synchronized to the system clock (SYSCLKOUT). A minimum of 1 SYSCLKOUT low pulse on the $\overline{\text{TZ}}$ $\overline{\text{n}}$ inputs is sufficient to trigger a fault condition in the ePWM module. The asynchronous trip makes sure that if clocks are missing for any reason, the outputs can still be tripped by a valid event present on the $\overline{\text{TZn}}$ inputs.

The $\overline{\text{TZ}}$ $\overline{\text{n}}$ input can be individually configured to provide either a cycle-by-cycle or one-shot trip event for a ePWM module. The configuration is determined by the TZSEL[CBCn] and TZSEL[OSHTn] bits (where n corresponds to the trip pin) respectively.

- **Cycle-by-Cycle (CBC):** When a cycle-by-cycle trip event occurs, the action specified in the TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. Table 20-37 lists the possible actions. In addition, the cycle-by-cycle trip event flag (TZFLG[CBC]) is set and a EPWMxTZINT interrupt is generated if it is enabled in the TZEINT register.

  The specified condition on the pins is automatically cleared when the ePWM time-base counter reaches zero (TBCNT = 0000h) if the trip event is no longer present. Therefore, in this mode, the trip event is cleared or reset every PWM cycle. The TZFLG[CBC] flag bit will remain set until it is manually cleared by writing to the TZCLR[CBC] bit. If the cycle-by-cycle trip event is still present when the TZFLG[CBC] bit is cleared, then it will again be immediately set.
- **One-Shot (OSHT):** When a one-shot trip event occurs, the action specified in the TZCTL register is carried out immediately on the EPWMxA and/or EPWMxB output. Table 20-37 lists the possible actions. In addition, the one-shot trip event flag (TZFLG[OST]) is set and a EPWMxTZINT interrupt is generated if it is enabled in the TZEINT register. The one-shot trip condition must be cleared manually by writing to the TZCLR[OST] bit.

The action taken when a trip event occurs can be configured individually for each of the ePWM output pins by way of the TZCTL[TZA] and TZCTL[TZB] register bits. One of four possible actions, shown in Table 20-37, can be taken on a trip event.

Table 20-37. Possible Actions On a Trip Event

TZCTL[TZA] and/or TZCTL[TZB]	EPWMxA and/or EPWMxB	Comment
0	High-Impedance	Tripped
1h	Force to High State	Tripped
2h	Force to Low State	Tripped
3h	No Change	Do Nothing. No change is made to the output.

Example 20-2. Trip-Zone Configurations

Scenario A:
A one-shot trip event on $\overline{\text{TZ1}}$ pulls both EPWM1A, EPWM1B low and also forces EPWM2A and EPWM2B high.

- Configure the ePWM1 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{\text{TZ}}$ as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{\text{TZ}}$ as a one-shot event source for ePWM2
  - TZCTL[TZA] = 1: EPWM2A will be forced high on a trip event.
  - TZCTL[TZB] = 1: EPWM2B will be forced high on a trip event.

Scenario B:
A cycle-by-cycle event on $\overline{\text{TZ5}}$ pulls both EPWM1A, EPWM1B low.

A one-shot event on $\overline{\text{TZ1}}$ or $\overline{\text{TZ6}}$ puts EPWM2A into a high impedance state.

- Configure the ePWM1 registers as follows:
  - TZSEL[CBC5] = 1: enables $\overline{\text{TZ5}}$ as a one-shot event source for ePWM1
  - TZCTL[TZA] = 2: EPWM1A will be forced low on a trip event.
  - TZCTL[TZB] = 2: EPWM1B will be forced low on a trip event.
- Configure the ePWM2 registers as follows:
  - TZSEL[OSHT1] = 1: enables $\overline{\text{TZ1}}$ as a one-shot event source for ePWM2
  - TZSEL[OSHT6] = 1: enables $\overline{\text{TZ6}}$ as a one-shot event source for ePWM1
  - TZCTL[TZA] = 0: EPWM1A will be put into a high-impedance state on a trip event.
  - TZCTL[TZB] = 3: EPWM1B will ignore the trip event.

20.2.2.8.4 Generating Trip Event Interrupts

Figure 20-43 and Figure 20-44 illustrate the trip-zone submodule control and interrupt logic, respectively.

Figure 20-43. Trip-Zone Submodule Mode Control Logic

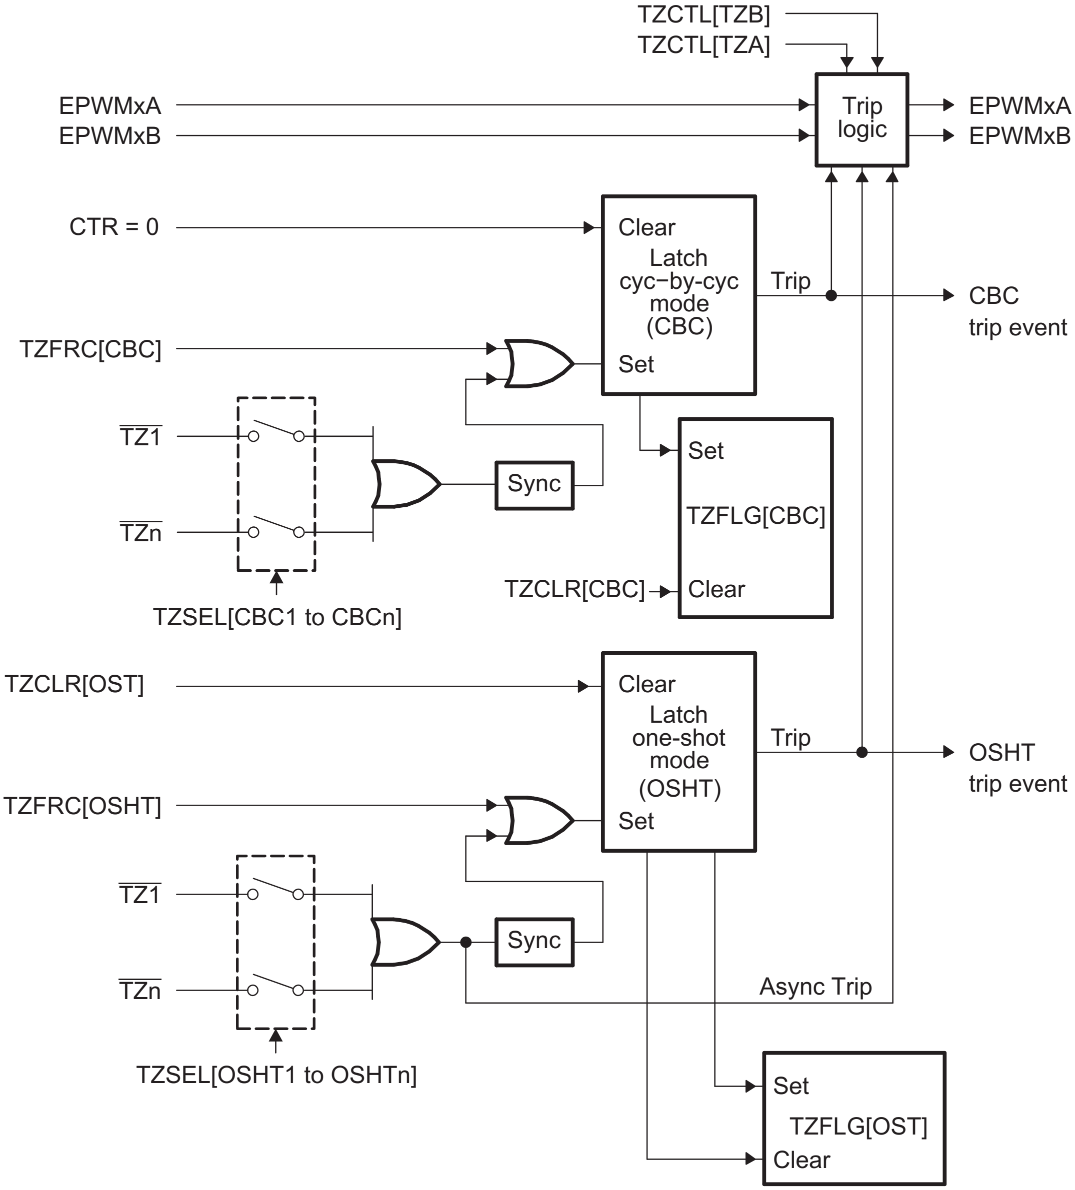


Figure 20-44. Trip-Zone Submodule Interrupt Logic

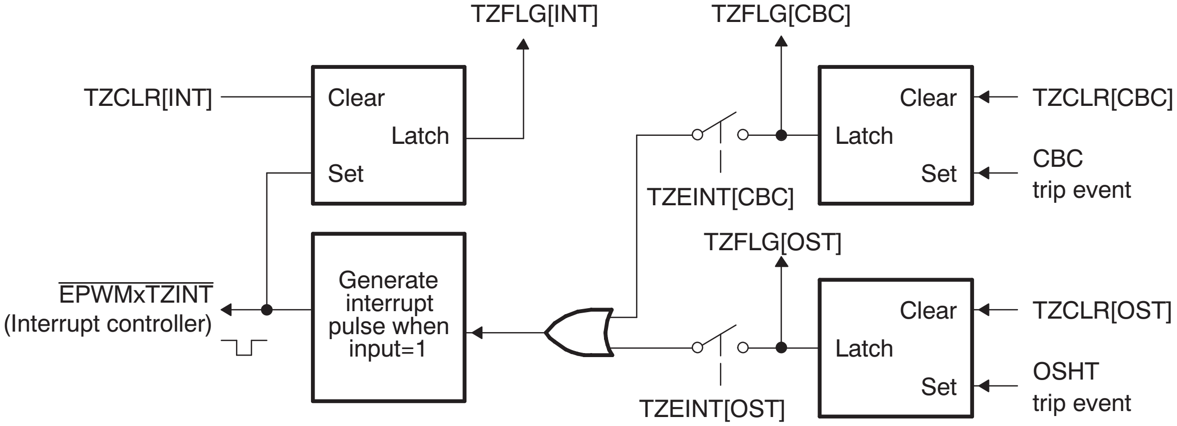
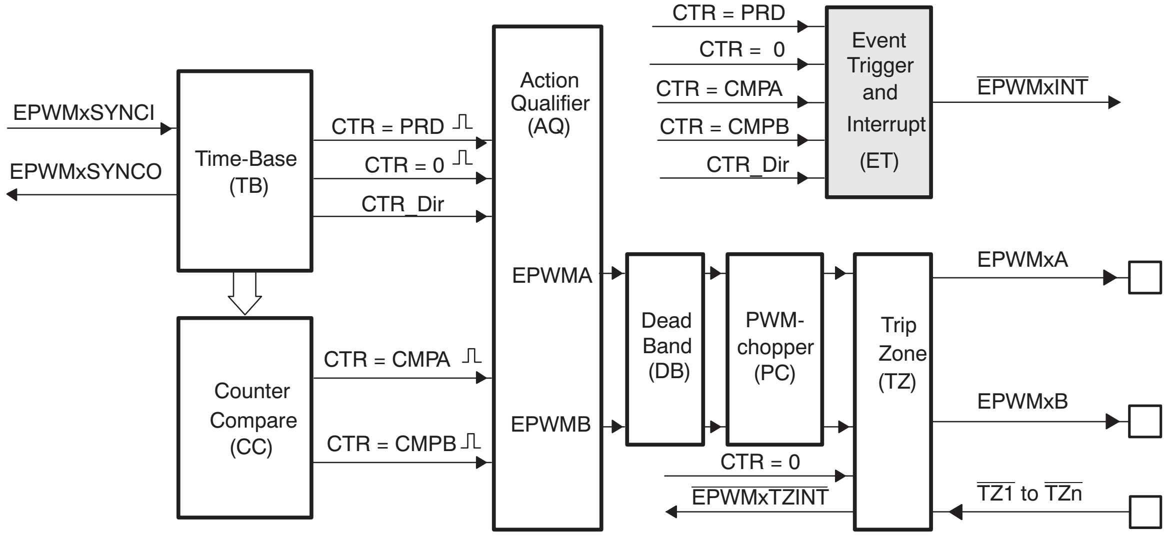


20.2.2.9 Event-Trigger (ET) Submodule

Figure 20-45 shows the event-trigger (ET) submodule in the ePWM system. The event-trigger submodule manages the events generated by the time-base submodule and the counter-compare submodule to generate an interrupt to the CPU.

Figure 20-45. Event-Trigger Submodule



20.2.2.9.1 Purpose of the Event-Trigger Submodule

The key functions of the event-trigger submodule are:

- Receives event inputs generated by the time-base and counter-compare submodules
- Uses the time-base direction information for up/down event qualification
- Uses prescaling logic to issue interrupt requests at:
  - Every event
  - Every second event
  - Every third event
- Provides full visibility of event generation via event counters and flags

20.2.2.9.2 Controlling and Monitoring the Event-Trigger Submodule

The key registers used to configure the event-trigger submodule are shown in Table 20-38:

Table 20-38. Event-Trigger Submodule Registers

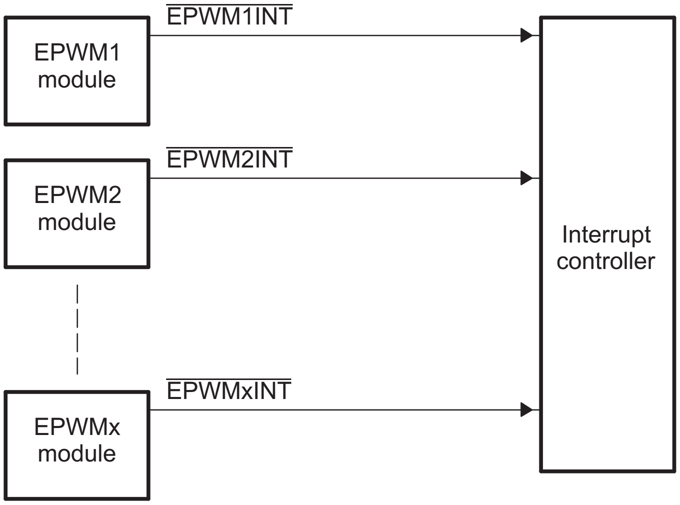
Acronym	Register Description	Address Offset	Shadowed
ETSEL	Event-Trigger Selection Register	32h	No
ETPS	Event-Trigger Prescale Register	34h	No
ETFLG	Event-Trigger Flag Register	36h	No
ETCLR	Event-Trigger Clear Register	38h	No
ETFRC	Event-Trigger Force Register	3Ah	No

20.2.2.9.3 Operational Overview of the Event-Trigger Submodule

The following sections describe the event-trigger submodule's operational highlights.

Each ePWM module has one interrupt request line connected to the interrupt controller as shown in Figure 20-46.

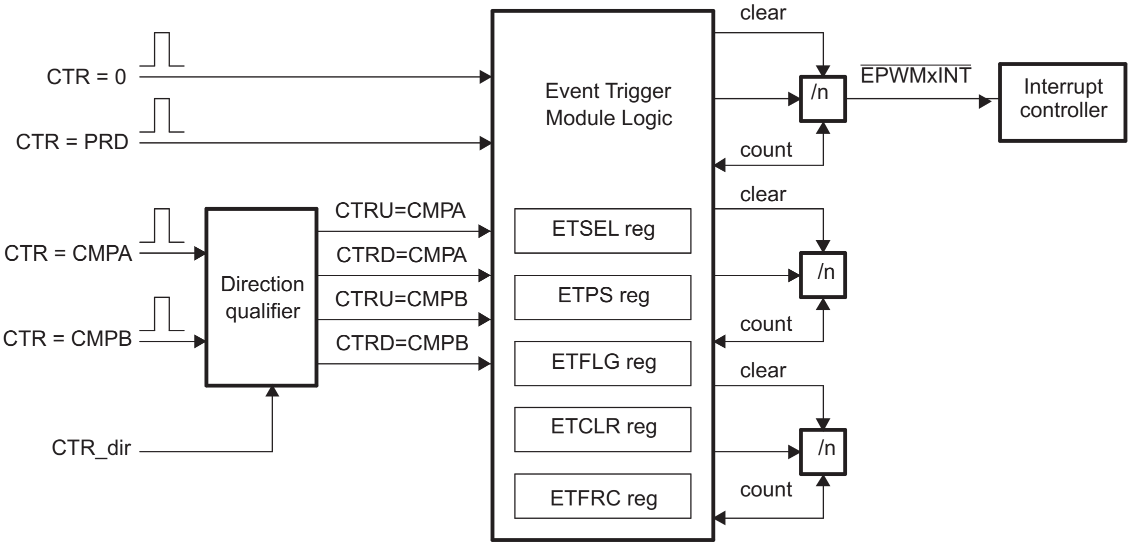
Figure 20-46. Event-Trigger Submodule Inter-Connectivity to Interrupt Controller



The event-trigger submodule monitors various event conditions (the left side inputs to event-trigger submodule shown in Figure 20-47) and can be configured to prescale these events before issuing an Interrupt request. The event-trigger prescaling logic can issue Interrupt requests at:

- Every event
- Every second event
- Every third event

Figure 20-47. Event-Trigger Submodule Showing Event Inputs and Prescaled Outputs



- ETSEL—This selects which of the possible events will trigger an interrupt.
- ETPS—This programs the event prescaling options previously mentioned.
- ETFLG—These are flag bits indicating status of the selected and prescaled events.
- ETCLR—These bits allow you to clear the flag bits in the ETFLG register via software.
- ETFRC—These bits allow software forcing of an event. Useful for debugging or software intervention.

A more detailed look at how the various register bits interact with the Interrupt is shown in Figure 20-48.

Figure 20-48 shows the event-trigger's interrupt generation logic. The interrupt-period (ETPS[INTPRD]) bits specify the number of events required to cause an interrupt pulse to be generated. The choices available are:

- Do not generate an interrupt
- Generate an interrupt on every event
- Generate an interrupt on every second event
- Generate an interrupt on every third event

An interrupt cannot be generated on every fourth or more events.

Which event can cause an interrupt is configured by the interrupt selection (ETSEL[INTSEL]) bits. The event can be one of the following:

- Time-base counter equal to zero (TBCNT = 0000h).
- Time-base counter equal to period (TBCNT = TBPRD).
- Time-base counter equal to the compare A register (CMPA) when the timer is incrementing.
- Time-base counter equal to the compare A register (CMPA) when the timer is decrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is incrementing.
- Time-base counter equal to the compare B register (CMPB) when the timer is decrementing.

The number of events that have occurred can be read from the interrupt event counter (ETPS[INTCNT]) register bits. That is, when the specified event occurs the ETPS[INTCNT] bits are incremented until they reach the value specified by ETPS[INTPRD]. When ETPS[INTCNT] = ETPS[INTPRD] the counter stops counting and its output is set. The counter is only cleared when an interrupt is sent to the interrupt controller.

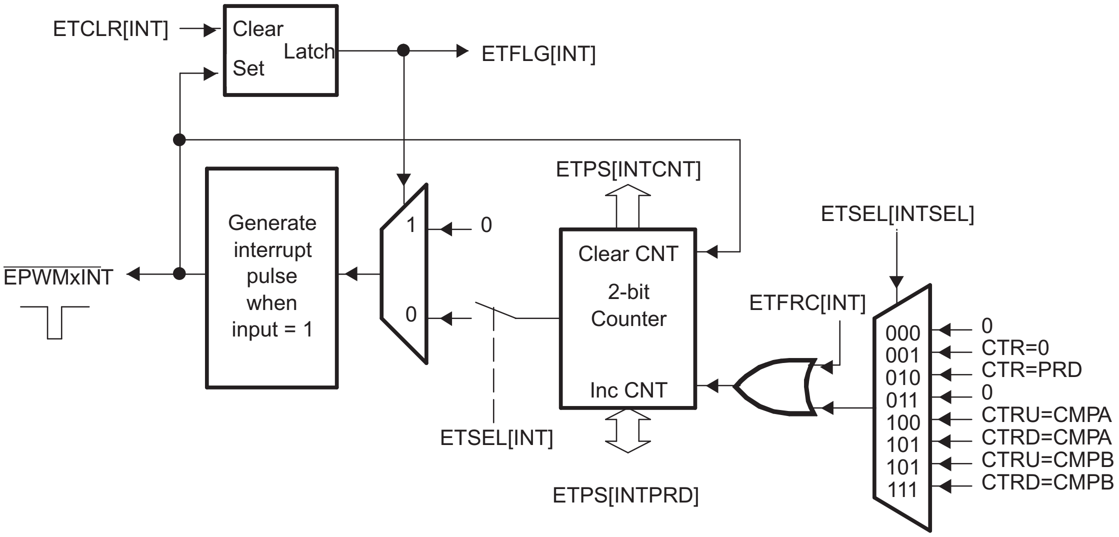
When ETPS[INTCNT] reaches ETPS[INTPRD], one of the following behaviors will occur:

- If interrupts are enabled, ETSEL[INTEN] = 1 and the interrupt flag is clear, ETFLG[INT] = 0, then an interrupt pulse is generated and the interrupt flag is set, ETFLG[INT] = 1, and the event counter is cleared ETPS[INTCNT] = 0. The counter will begin counting events again.
- If interrupts are disabled, ETSEL[INTEN] = 0, or the interrupt flag is set, ETFLG[INT] = 1, the counter stops counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD].
- If interrupts are enabled, but the interrupt flag is already set, then the counter will hold its output high until the ENTFLG[INT] flag is cleared. This allows for one interrupt to be pending while one is serviced.

Writing to the INTPRD bits will automatically clear the counter INTCNT = 0 and the counter output will be reset (so no interrupts are generated). Writing a 1 to the ETFRC[INT] bit will increment the event counter INTCNT. The counter will behave as described above when INTCNT = INTPRD. When INTPRD = 0, the counter is disabled and hence no events will be detected and the ETFRC[INT] bit is also ignored.

Note that the interrupts coming from the ePWM module are also used as DMA events. The interrupt registers should be used to enable and clear the current DMA event in order for the ePWM module to generate subsequent DMA events.

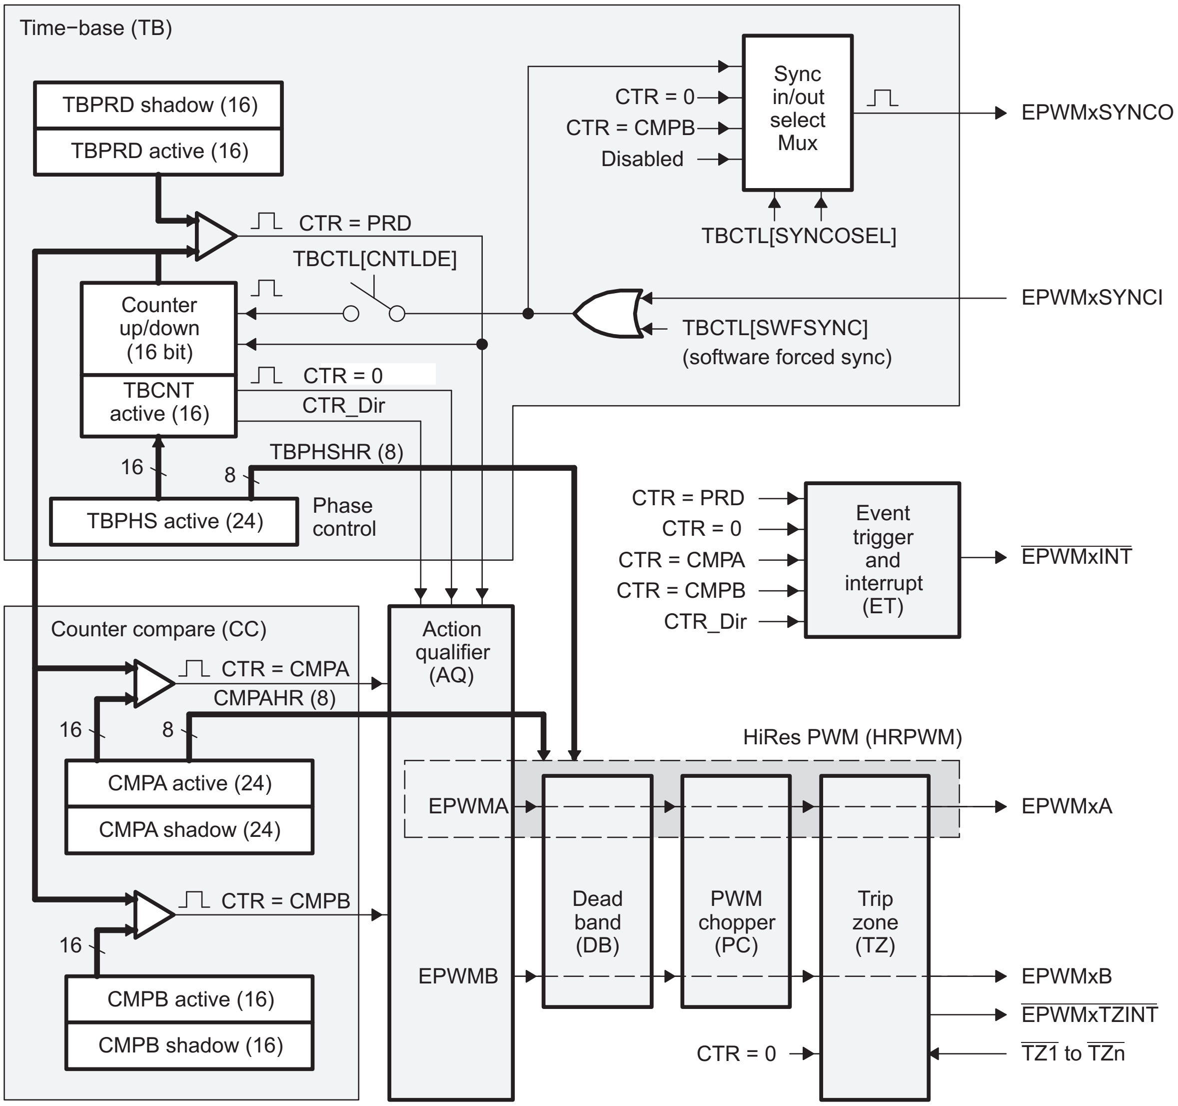
Figure 20-48. Event-Trigger Interrupt Generator



20.2.2.10 High-Resolution PWM (HRPWM) Submodule

Figure 20-49 shows the high-resolution PWM (HRPWM) submodule in the ePWM system. Some devices include the high-resolution PWM submodule, see Section 20.1.2 to determine which ePWM instances include this feature.

Figure 20-49. HRPWM System Interface



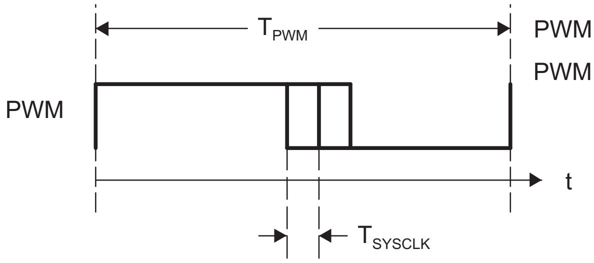
20.2.2.10.1 Purpose of the High-Resolution PWM Submodule

The enhanced high-resolution pulse-width modulator (eHRPWM) extends the time resolution capabilities of the conventionally derived digital pulse-width modulator (PWM). HRPWM is typically used when PWM resolution falls below ~9-10 bits. The key features of HRPWM are:

- Extended time resolution capability
- Used in both duty cycle and phase-shift control methods
- Finer time granularity control or edge positioning using extensions to the Compare A and Phase registers
- Implemented using the A signal path of PWM, that is, on the EPWMxA output. EPWMxB output has conventional PWM capabilities

The ePWM peripheral is used to perform a function that is mathematically equivalent to a digital-to-analog converter (DAC). As shown in Figure 20-50, the effective resolution for conventionally generated PWM is a function of PWM frequency (or period) and system clock frequency.

Figure 20-50. Resolution Calculations for Conventionally Generated PWM



PWM resolution (%) = $F_{PWM}/F_{SYSCLKOUT}$ x 100%

PWM resolution (bits) = $\text{Log}_2\,(F_{PWM}/F_{SYSCLKOUT})$

If the required PWM operating frequency does not offer sufficient resolution in PWM mode, you may want to consider HRPWM. As an example of improved performance offered by HRPWM, Table 20-39 shows resolution in bits for various PWM frequencies. Table 20-39 values assume a MEP step size of 180 ps. See your device-specific data manual for typical and maximum performance specifications for the MEP.

Table 20-39. Resolution for PWM and HRPWM

	Regular Resolution (PWM)		High Resolution (HRPWM)	
PWM Frequency (kHz)	**Bits**	**%**	**Bits**	**%**
20	12.3	0.0	18.1	0.000
50	11.0	0.0	16.8	0.001
100	10.0	0.1	15.8	0.002
150	9.4	0.2	15.2	0.003
200	9.0	0.2	14.8	0.004
250	8.6	0.3	14.4	0.005
500	7.6	0.5	13.8	0.007
1000	6.6	1.0	12.4	0.018
1500	6.1	1.5	11.9	0.027
2000	5.6	2.0	11.4	0.036

Although each application may differ, typical low-frequency PWM operation (below 250 kHz) may not require HRPWM. HRPWM capability is most useful for high-frequency PWM requirements of power conversion topologies such as:

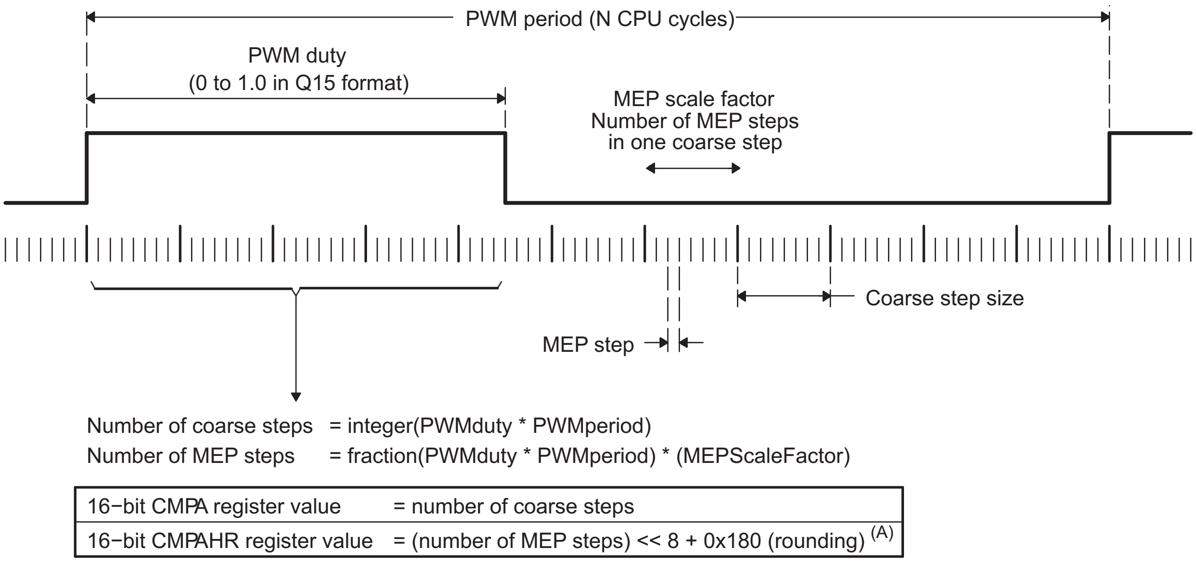
- Single-phase buck, boost, and flyback
- Multi-phase buck, boost, and flyback
- Phase-shifted full bridge
- Direct modulation of D-Class power amplifiers

20.2.2.10.2 Architecture of the High-Resolution PWM Submodule

The HRPWM is based on micro edge positioner (MEP) technology. MEP logic is capable of positioning an edge very finely by sub-dividing one coarse system clock of a conventional PWM generator. The time step accuracy is on the order of 150 ps. The HRPWM also has a self-check software diagnostics mode to check if the MEP logic is running optimally, under all operating conditions.

Figure 20-51 shows the relationship between one coarse system clock and edge position in terms of MEP steps, which are controlled via an 8-bit field in the Compare A extension register (CMPAHR).

Figure 20-51. Operating Logic Using MEP



A For MEP range and rounding adjustment.

To generate an HRPWM waveform, configure the TBM, CCM, and AQM registers as you would to generate a conventional PWM of a given frequency and polarity. The HRPWM works together with the TBM, CCM, and AQM registers to extend edge resolution, and should be configured accordingly. Although many programming combinations are possible, only a few are needed and practical.

20.2.2.10.3 Controlling and Monitoring the High-Resolution PWM Submodule

The MEP of the HRPWM is controlled by two extension registers, each 8-bits wide. These two HRPWM registers are concatenated with the 16-bit TBPHS and CMPA registers used to control PWM operation.

- TBPHSHR - Time-Base Phase High-Resolution Register
- CMPAHR - Counter-Compare A High-Resolution Register

Table 20-40 lists the registers used to control and monitor the high-resolution PWM submodule.

Table 20-40. HRPWM Submodule Registers

Acronym	Register Description	Address Offset	Shadowed
TBPHSHR	Extension Register for HRPWM Phase	4h	No
CMPAHR	Extension Register for HRPWM Duty	10h	Yes
HRCTL	HRPWM Configuration Register	C0h	No

20.2.2.10.4 Configuring the High-Resolution PWM Submodule

Once the ePWM has been configured to provide conventional PWM of a given frequency and polarity, the HRPWM is configured by programming the HRCTL register located at offset address C0h. This register provides configuration options for the following key operating modes:

- **Edge Mode:** The MEP can be programmed to provide precise position control on the rising edge (RE), falling edge (FE), or both edges (BE) at the same time. FE and RE are used for power topologies requiring duty cycle control, while BE is used for topologies requiring phase shifting, for example, phase shifted full bridge.
- **Control Mode:** The MEP is programmed to be controlled either from the CMPAHR register (duty cycle control) or the TBPHSHR register (phase control). RE or FE control mode should be used with CMPAHR register. BE control mode should be used with TBPHSHR register.
- **Shadow Mode:** This mode provides the same shadowing (double buffering) option as in regular PWM mode. This option is valid only when operating from the CMPAHR register and should be chosen to be the same as the regular load option for the CMPA register. If TBPHSHR is used, then this option has no effect.

20.2.2.10.5 Operational Highlights for the High-Resolution PWM Submodule

The MEP logic is capable of placing an edge in one of 255 (8 bits) discrete time steps, each of which has a time resolution on the order of 150 ps. The MEP works with the TBM and CCM registers to be certain that time steps are optimally applied and that edge placement accuracy is maintained over a wide range of PWM frequencies, system clock frequencies and other operating conditions. Table 20-41 shows the typical range of operating frequencies supported by the HRPWM.

Table 20-41. Relationship Between MEP Steps, PWM Frequency and Resolution

System (MHz)	MEP Steps Per SYSCLKOUT[1] [2] [3]	PWM Minimum (Hz)[4]	PWM Maximum (MHz)	Resolution at Maximum (Bits)[5]
50.0	111	763	2.50	11.1
60.0	93	916	3.00	10.9
70.0	79	1068	3.50	10.6
80.0	69	1221	4.00	10.4
90.0	62	1373	4.50	10.3
100.0	56	1526	5.00	10.1

[1] System frequency = SYSCLKOUT, that is, CPU clock. TBCLK = SYSCLKOUT

[2] Table data based on a MEP time resolution of 180 ps (this is an example value)

[3] MEP steps applied = $T_{SYSCLKOUT}$/180 ps in this example.

[4] PWM minimum frequency is based on a maximum period value, TBPRD = 65 535. PWM mode is asymmetrical up-count.

[5] Resolution in bits is given for the maximum PWM frequency stated.

20.2.2.10.5.1 Edge Positioning

In a typical power control loop (switch modes, digital motor control (DMC), uninterruptible power supply (UPS)), a digital controller (PID, 2pole/2zero, lag/lead, etc.) issues a duty command, usually expressed in a per unit or percentage terms.

In the following example, assume that for a particular operating point, the demanded duty cycle is 0.405 or 40.5% on-time and the required converter PWM frequency is 1.25 MHz. In conventional PWM generation with a system clock of 100 MHz, the duty cycle choices are in the vicinity of 40.5%. In Figure 20-52, a compare value of 32 counts (duty = 40%) is the closest to 40.5% that you can attain. This is equivalent to an edge position of 320 ns instead of the desired 324 ns. This data is shown in Table 20-42.

By utilizing the MEP, you can achieve an edge position much closer to the desired point of 324 ns. Table 20-42 shows that in addition to the CMPA value, 22 steps of the MEP (CMPAHR register) will position the edge at 323.96 ns, resulting in almost zero error. In this example, it is assumed that the MEP has a step resolution of 180 ns.

Figure 20-52. Required PWM Waveform for a Requested Duty = 40.5%

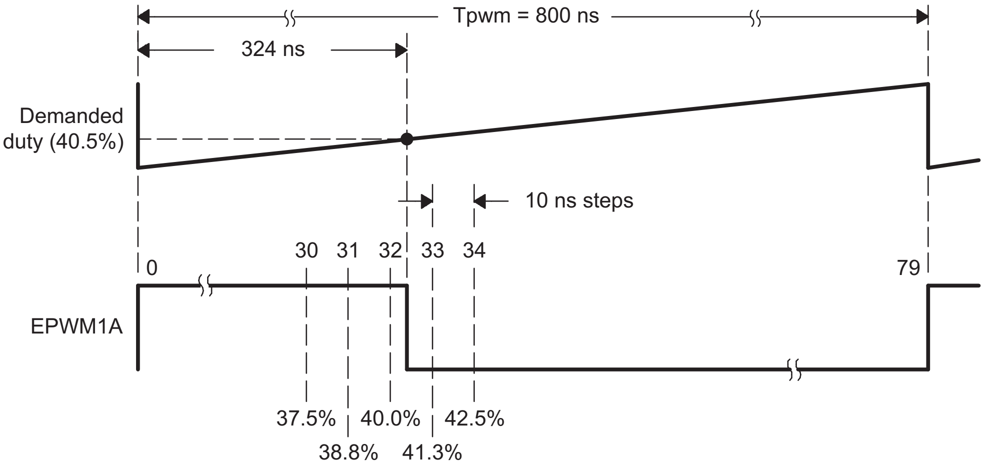


Table 20-42. CMPA vs Duty (left), and [CMPA:CMPAHR] vs Duty (right)

CMPA (count)(1) (2) (3)	DUTY (%)	High Time (ns)	CMPA (count)	CMPAHR (count)	Duty (%)	High Time (ns)
28	35.0	280	32	18	40.405	323.24
29	36.3	290	32	19	40.428	323.42
30	37.5	300	32	20	40.450	323.60
31	38.8	310	32	21	40.473	323.78
32	40.0	320	32	22	40.495	323.96
33	41.3	330	32	23	40.518	324.14
34	42.5	340	32	24	40.540	324.32
			32	25	40.563	324.50
Required			32	26	40.585	324.68
32.40	40.5	324	32	27	40.608	324.86

(1) System clock, SYSCLKOUT and TBCLK = 100 MHz, 10 ns

(2) For a PWM Period register value of 80 counts, PWM Period = 80 × 10 ns = 800 ns, PWM frequency = 1/800 ns = 1.25 MHz

(3) Assumed MEP step size for the above example = 180 ps

20.2.2.10.5.2 Scaling Considerations

The mechanics of how to position an edge precisely in time has been demonstrated using the resources of the standard (CMPA) and MEP (CMPAHR) registers. In a practical application, however, it is necessary to seamlessly provide the CPU a mapping function from a per-unit (fractional) duty cycle to a final integer (non-fractional) representation that is written to the [CMPA:CMPAHR] register combination.

To do this, first examine the scaling or mapping steps involved. It is common in control software to express duty cycle in a per-unit or percentage basis. This has the advantage of performing all needed math calculations without concern for the final absolute duty cycle, expressed in clock counts or high time in ns. Furthermore, it makes the code more transportable across multiple converter types running different PWM frequencies.

To implement the mapping scheme, a two-step scaling procedure is required.

Assumptions for this example:

System clock, SYSCLKOUT = 10 ns (100 MHz)
PWM frequency = 1.25 MHz (1/800 ns)
Required PWM duty cycle, **PWMDuty** = 0.405 (40.5%)
PWM period in terms of coarse steps, **PWMperiod** (800 ns/10 ns) = 80
Number of MEP steps per coarse step at 180 ps (10 ns/180 ps), **MEP_SF** = 55
Value to keep CMPAHR within the range of 1-255 and fractional rounding constant (default value) = 180h

Step 1: Percentage Integer Duty value conversion for CMPA register

CMPA register value = int(**PWMDuty** × **PWMperiod**); int means integer part
= int(0.405 × 80)
= int(32.4)
CMPA register value = 32 (20h)

Step 2: Fractional value conversion for CMPAHR register

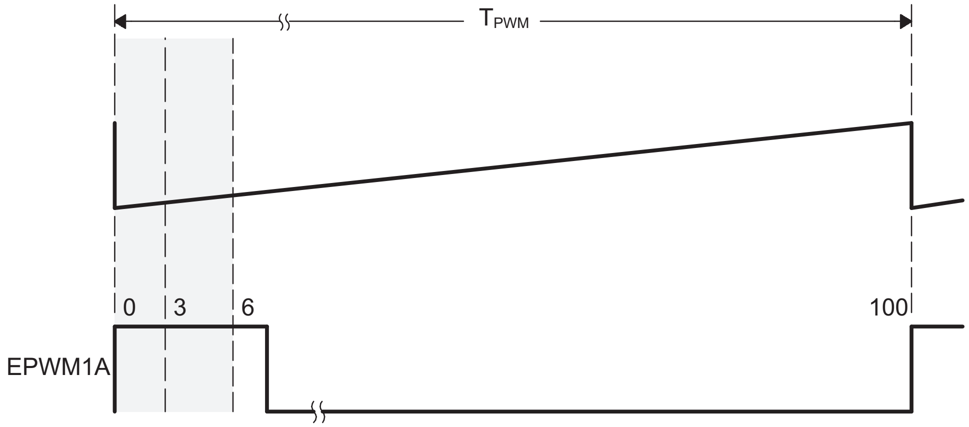
CMPAHR register value = (frac(**PWMDuty** × **PWMperiod**) × **MEP_SF**) << 8) + 180h; frac means fractional part
= (frac(32.4) × 55 <<8) + 180h; Shift is to move the value as CMPAHR high byte
= ((0.4 × 55) <<8) + 180h
= (22 <<8) + 180h
= 22 × 256 + 180h ; Shifting left by 8 is the same multiplying by 256.
= 5632 + 180h
= 1600h + 180h
CMPAHR value = 1780h; CMPAHR value = 1700h, lower 8 bits will be ignored by hardware.

20.2.2.10.5.3 Duty Cycle Range Limitation

In high resolution mode, the MEP is not active for 100% of the PWM period. It becomes operational 3 SYSCLK cycles after the period starts.

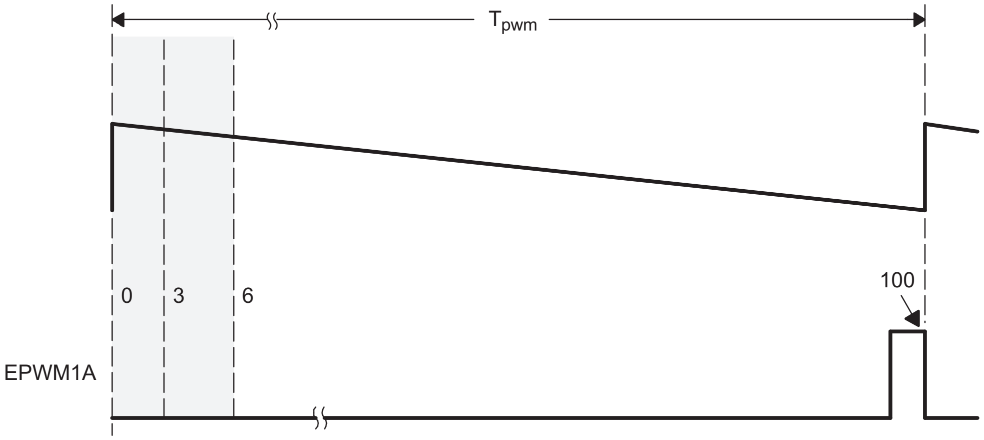
Duty cycle range limitations are illustrated in Figure 20-53. This limitation imposes a lower duty cycle limit on the MEP. For example, precision edge control is not available all the way down to 0% duty cycle. Although for the first 3 or 6 cycles, the HRPWM capabilities are not available, regular PWM duty control is still fully operational down to 0% duty. In most applications this should not be an issue as the controller regulation point is usually not designed to be close to 0% duty cycle.

Figure 20-53. Low % Duty Cycle Range Limitation Example When PWM Frequency = 1 MHz



If the application demands HRPWM operation in the low percent duty cycle region, then the HRPWM can be configured to operate in count-down mode with the rising edge position (REP) controlled by the MEP. This is illustrated in Figure 20-54. In this case low percent duty limitation is no longer an issue.

Figure 20-54. High % Duty Cycle Range Limitation Example when PWM Frequency = 1 MHz



20.2.2.11 ePWM Behavior During Emulation

To configure the ePWM to stop during emulation suspend events (for example, debugger breakpoints), set up the ePWM and the Debug Subsystem:

1. Set TBCTL.FREE_SOFT= 0 or 1 (see register description for more details). This will allow the Suspend_Control signal from the Debug Subsystem (Chapter 31) to stop and start the ePWM. Note that if FREE_SOFT = 2 or 3, the Suspend_Control signal is ignored and the ePWM is free running regardless of any debug suspend event. This FREE_SOFT bit gives local control from a module perspective to gate the suspend signal coming from the Debug Subsystem.
2. Set the appropriate xxx_Suspend_Control register = 0x9, as described in Section 31.1.1.1, *Debug Suspend Support for Peripherals*. Choose the register appropriate to the peripheral you want to suspend during a suspend event.

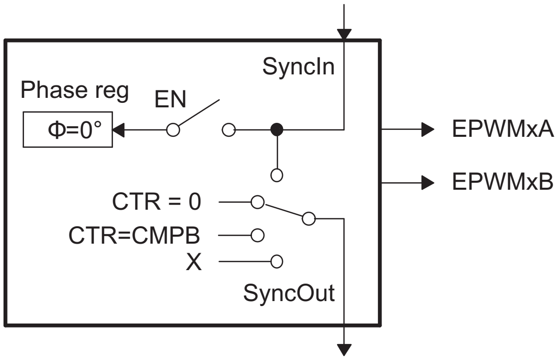
20.2.3 Use Cases

An ePWM module has all the local resources necessary to operate completely as a standalone module or to operate in synchronization with other identical ePWM modules.

20.2.3.1 Overview of Multiple Modules

Previously in this user's guide, all discussions have described the operation of a single module. To facilitate the understanding of multiple modules working together in a system, the ePWM module described in reference is represented by the more simplified block diagram shown in Figure 20-55. This simplified ePWM block shows only the key resources needed to explain how a multiswitch power topology is controlled with multiple ePWM modules working together.

Figure 20-55. Simplified ePWM Module



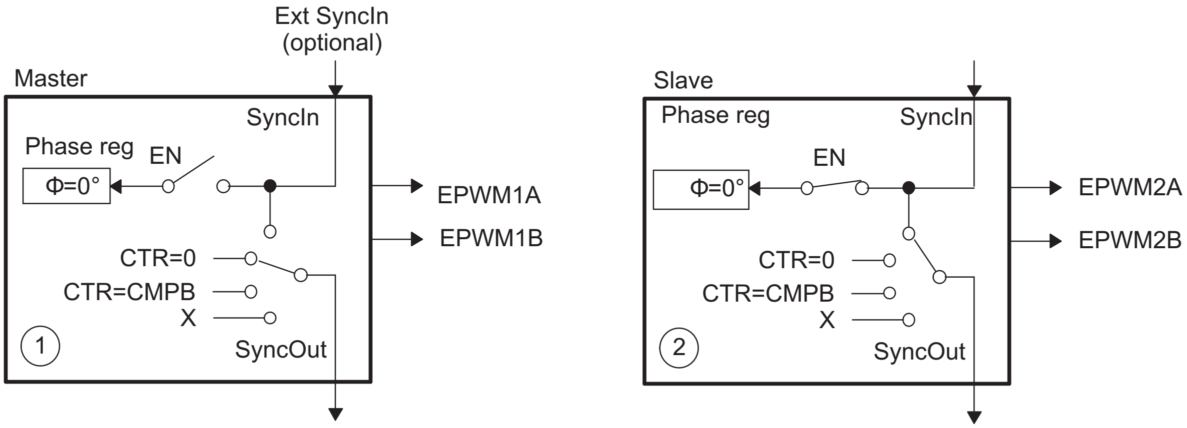
20.2.3.2 Key Configuration Capabilities

The key configuration choices available to each module are as follows:

- Options for SyncIn
  - Load own counter with phase register on an incoming sync strobe—enable (EN) switch closed
  - Do nothing or ignore incoming sync strobe—enable switch open
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)
- Options for SyncOut
  - Sync flow-through - SyncOut connected to SyncIn
  - Master mode, provides a sync at PWM boundaries—SyncOut connected to CTR = PRD
  - Master mode, provides a sync at any programmable point in time—SyncOut connected to CTR = CMPB
  - Module is in standalone mode and provides No sync to other modules—SyncOut connected to X (disabled)

For each choice of SyncOut, a module may also choose to load its own counter with a new phase value on a SyncIn strobe input or choose to ignore it, i.e., via the enable switch. Although various combinations are possible, the two most common—master module and slave module modes—are shown in Figure 20-56.

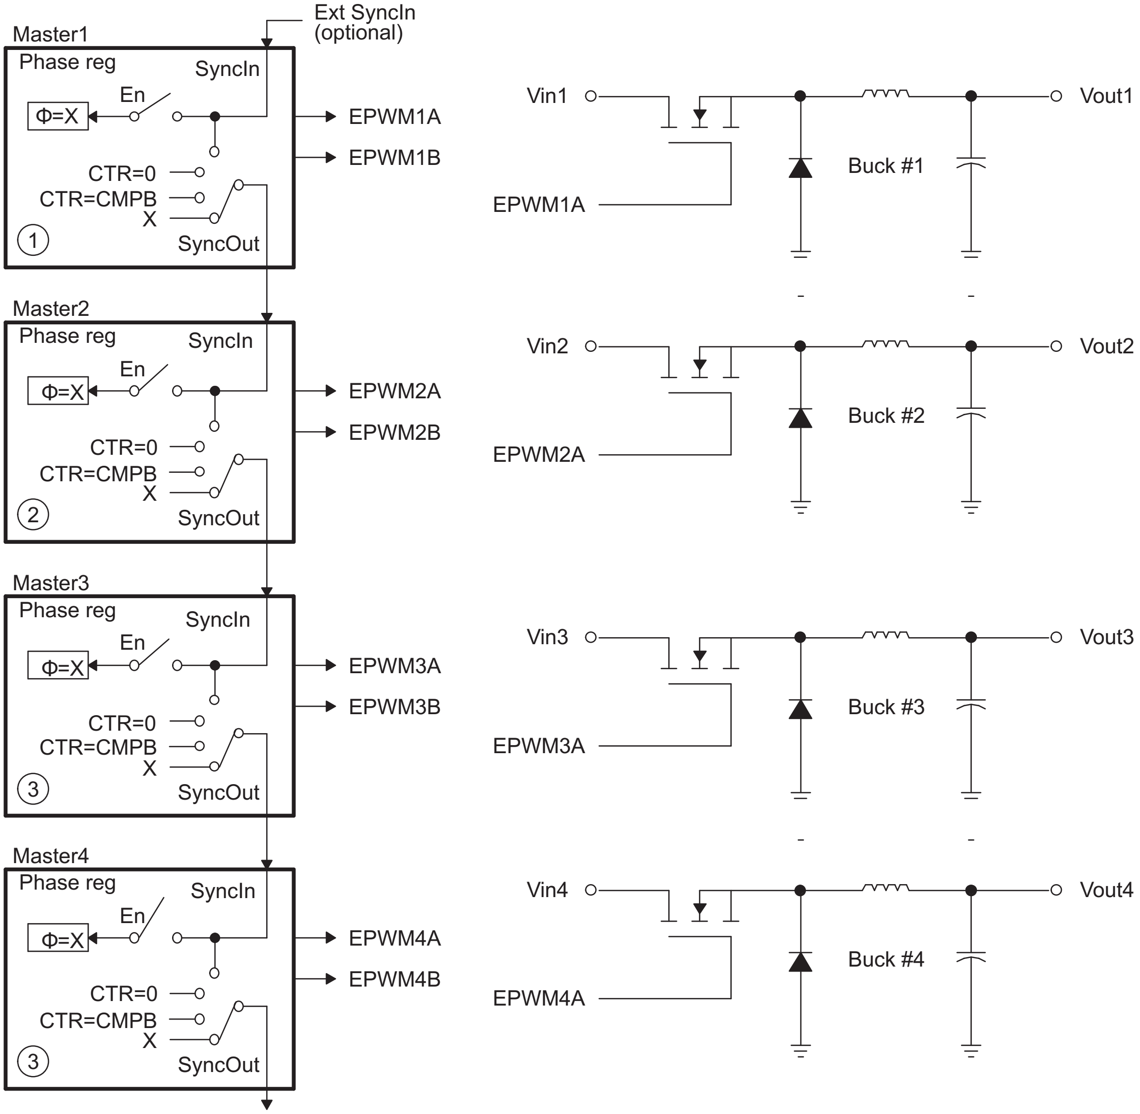
Figure 20-56. EPWM1 Configured as a Typical Master, EPWM2 Configured as a Slave



20.2.3.3 Controlling Multiple Buck Converters With Independent Frequencies

One of the simplest power converter topologies is the buck. A single ePWM module configured as a master can control two buck stages with the same PWM frequency. If independent frequency control is required for each buck converter, then one ePWM module must be allocated for each converter stage. Figure 20-57 shows four buck stages, each running at independent frequencies. In this case, all four ePWM modules are configured as Masters and no synchronization is used. Figure 20-58 shows the waveforms generated by the setup shown in Figure 20-57; note that only three waveforms are shown, although there are four stages.

Figure 20-57. Control of Four Buck Stages. Here $F_{PWM1} \neq F_{PWM2} \neq F_{PWM3} \neq F_{PWM4}$



NOTE: Θ = X indicates value in phase register is a "don't care"

Figure 20-58. Buck Waveforms for Figure 20-57 (Note: Only three bucks shown here)

```
// Run Time (Note: Example execution of one run-time instance)
//===========================================================
    EPwm1Regs.CMPA.half.CMPA = 700;               // adjust duty for output EPWM1A
    EPwm2Regs.CMPA.half.CMPA = 700;               // adjust duty for output EPWM2A
    EPwm3Regs.CMPA.half.CMPA = 500;               // adjust duty for output EPWM3A
```

20.2.3.4 Controlling Multiple Buck Converters With Same Frequencies

If synchronization is a requirement, ePWM module 2 can be configured as a slave and can operate at integer multiple (N) frequencies of module 1. The sync signal from master to slave ensures these modules remain locked. Figure 20-59 shows such a configuration; Figure 20-60 shows the waveforms generated by the configuration.

Figure 20-59. Control of Four Buck Stages. (Note: $F_{PWM2} = N \times F_{PWM1}$)

```
// Run Time (Note: Example execution of one run-time instance)
//=========================================================
     EPwm1Regs.CMPA.half.CMPA = 400;       // adjust duty for output EPWM1A
     EPwm1Regs.CMPB = 200;                 // adjust duty for output EPWM1B
     EPwm2Regs.CMPA.half.CMPA = 500;       // adjust duty for output EPWM2A
     EPwm2Regs.CMPB = 300;                 // adjust duty for output EPWM2B
```

20.2.3.5 Controlling Multiple Half H-Bridge (HHB) Converters

Topologies that require control of multiple switching elements can also be addressed with these same ePWM modules. It is possible to control a Half-H bridge stage with a single ePWM module. This control can be extended to multiple stages. Figure 20-61 shows control of two synchronized Half-H bridge stages where stage 2 can operate at integer multiple (N) frequencies of stage 1. Figure 20-62 shows the waveforms generated by the configuration shown in Figure 20-61.

Module 2 (slave) is configured for Sync flow-through; if required, this configuration allows for a third Half-H bridge to be controlled by PWM module 3 and also, most importantly, to remain in synchronization with master module 1.

Figure 20-61. Control of Two Half-H Bridge Stages ($F_{PWM2} = N \times F_{PWM1}$)

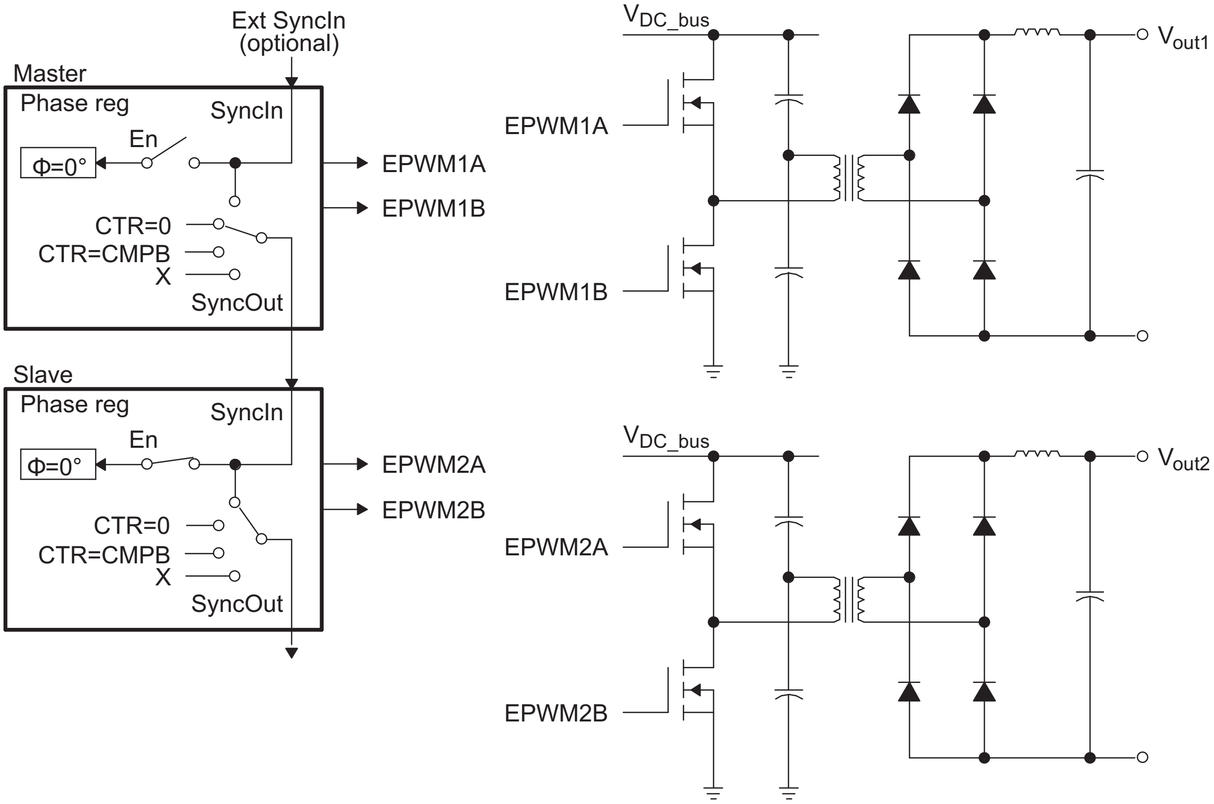

Figure 20-62. Half-H Bridge Waveforms for Figure 20-61 (Note: Here $F_{PWM2} = F_{PWM1}$)

```
// Run Time (Note: Example execution of one run-time instance)
//=========================================================
     EPwm1Regs.CMPA.half.CMPA = 400; // adjust duty for output EPWM1A
     EPwm1Regs.CMPB = 200;           // adjust duty for output EPWM1B
     EPwm2Regs.CMPA.half.CMPA = 500; // adjust duty for output EPWM2A
     EPwm2Regs.CMPB = 250;           // adjust duty for output EPWM2B
```

20.2.3.6 Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)

The idea of multiple modules controlling a single power stage can be extended to the 3-phase Inverter case. In such a case, six switching elements can be controlled using three PWM modules, one for each leg of the inverter. Each leg must switch at the same frequency and all legs must be synchronized. A master + two slaves configuration can easily address this requirement. Figure 20-63 shows how six PWM modules can control two independent 3-phase Inverters; each running a motor.

As in the cases shown in the previous sections, we have a choice of running each inverter at a different frequency (module 1 and module 4 are masters as in Figure 20-63), or both inverters can be synchronized by using one master (module 1) and five slaves. In this case, the frequency of modules 4, 5, and 6 (all equal) can be integer multiples of the frequency for modules 1, 2, 3 (also all equal).

```

20.2.3.7 Practical Applications Using Phase Control Between PWM Modules

So far, none of the examples have made use of the phase register (TBPHS). It has either been set to zero or its value has been a don't care. However, by programming appropriate values into TBPHS, multiple PWM modules can address another class of power topologies that rely on phase relationship between legs (or stages) for correct operation. As described in the TB module section, a PWM module can be configured to allow a SyncIn pulse to cause the TBPHS register to be loaded into the TBCNT register. To illustrate this concept, Figure 20-65 shows a master and slave module with a phase relationship of 120°, that is, the slave leads the master.

Figure 20-65. Configuring Two PWM Modules for Phase Control

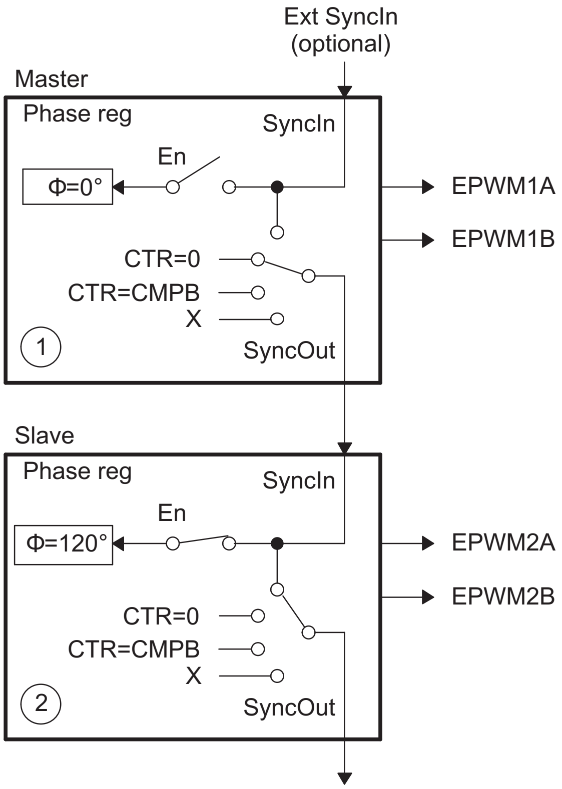

Figure 20-66 shows the associated timing waveforms for this configuration. Here, TBPRD = 600 for both master and slave. For the slave, TBPHS = 200 (200/600 × 360° = 120°). Whenever the master generates a SyncIn pulse (CTR = PRD), the value of TBPHS = 200 is loaded into the slave TBCNT register so the slave time-base is always leading the master's time-base by 120°.

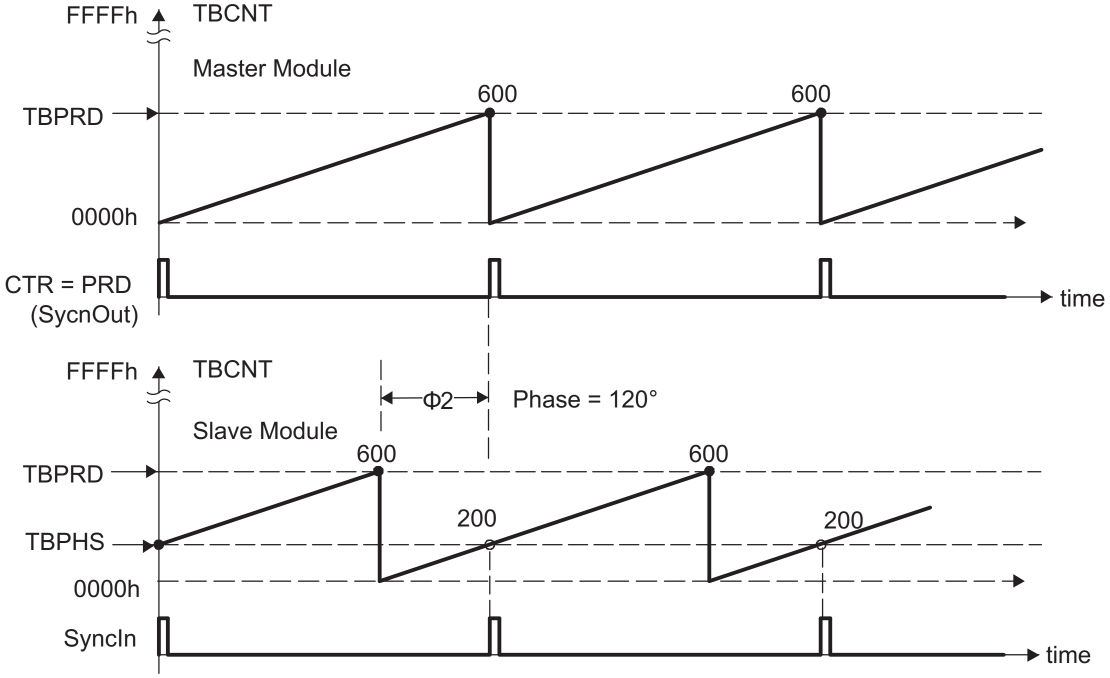
Figure 20-66. Timing Waveforms Associated With Phase Control Between 2 Modules



20.2.3.8 Controlling a 3-Phase Interleaved DC/DC Converter

A popular power topology that makes use of phase-offset between modules is shown in Figure 20-67. This system uses three PWM modules, with module 1 configured as the master. To work, the phase relationship between adjacent modules must be F = 120°. This is achieved by setting the slave TBPHS registers 2 and 3 with values of 1/3 and 2/3 of the period value, respectively. For example, if the period register is loaded with a value of 600 counts, then TBPHS (slave 2) = 200 and TBPHS (slave 3) = 400. Both slave modules are synchronized to the master 1 module.

This concept can be extended to four or more phases, by setting the TBPHS values appropriately. The following formula gives the TBPHS values for N phases:

TBPHS(N,M) = (TBPRD/N) × (M - 1)

Where:

N = number of phases

M = PWM module number

For example, for the 3-phase case (N = 3), TBPRD = 600,

TBPHS(3,2) = (600/3) × (2 - 1) = 200 × 1 = 200 (Phase value for Slave module 2)

TBPHS(3,3) = (600/3) × (3 - 1) = 200 × 2 = 400 (Phase value for Slave module 3)

Figure 20-68 shows the waveforms for the configuration in Figure 20-67.

```

20.2.3.9 Controlling Zero Voltage Switched Full Bridge (ZVSFB) Converter

The example given in Figure 20-69 assumes a static or constant phase relationship between legs (modules). In such a case, control is achieved by modulating the duty cycle. It is also possible to dynamically change the phase value on a cycle-by-cycle basis. This feature lends itself to controlling a class of power topologies known as *phase-shifted full bridge*, or *zero voltage switched full bridge.* Here the controlled parameter is not duty cycle (this is kept constant at approximately 50 percent); instead it is the phase relationship between legs. Such a system can be implemented by allocating the resources of two PWM modules to control a single power stage, which in turn requires control of four switching elements. Figure 20-70 shows a master/slave module combination synchronized together to control a full H-bridge. In this case, both master and slave modules are required to switch at the same PWM frequency. The phase is controlled by using the slave's phase register (TBPHS). The master's phase register is not used and therefore can be initialized to zero.

R/W-0h	R/W-0h	R/W-0h		R/W-0h	R/W-0h	R/W-0h	

Table 20-59. TBCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	FREE_SOFT	R/W	0h	Emulation Mode Bits. These bits select the behavior of the ePWM time-base counter during emulation suspend events. Emulation debug events can be set up in the Debug Subsystem. 0h (R/W) = Stop after the next time-base counter increment or decrement 1h (R/W) = Stop when counter completes a whole cycle. (a) Up-count mode: stop when the time-base counter = period (TBCNT = TBPRD). (b) Down-count mode: stop when the time-base counter = 0000 (TBCNT = 0000h). (c) Up-down-count mode: stop when the time-base counter = 0000 (TBCNT = 0000h). 2h (R/W) = Free run 3h (R/W) = Free run
13	PHSDIR	R/W	0h	Phase Direction Bit. This bit is only used when the time-base counter is configured in the up-down-count mode. The PHSDIR bit indicates the direction the time-base counter (TBCNT) will count after a synchronization event occurs and a new phase value is loaded from the phase (TBPHS) register. This is irrespective of the direction of the counter before the synchronization event.. In the up-count and down-count modes this bit is ignored. 0h (R/W) = Count down after the synchronization event. 1h (R/W) = Count up after the synchronization event.
12-10	CLKDIV	R/W	0h	Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value. TBCLK = SYSCLKOUT/(HSPCLKDIV * CLKDIV) 0h (R/W) = /1 (default on reset) 1h (R/W) = /2 2h (R/W) = /4 3h (R/W) = /8 4h (R/W) = /16 5h (R/W) = /32 6h (R/W) = /64 7h (R/W) = /128

Table 20-59. TBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9-7	HSPCLKDIV	R/W	0h	High-Speed Time-base Clock Prescale Bits. These bits determine part of the time-base clock prescale value. TBCLK = SYSCLKOUT/(HSPCLKDIV * CLKDIV). This divisor emulates the HSPCLK in the TMS320x281x system as used on the Event Manager (EV) peripheral. 0h (R/W) = /1 1h (R/W) = /2 (default on reset) 2h (R/W) = /4 3h (R/W) = /6 4h (R/W) = /8 5h (R/W) = /10 6h (R/W) = /12 7h (R/W) = /14
6	SWFSYNC	R/W	0h	Software Forced Synchronization Pulse. 0h (R/W) = Writing a 0 has no effect and reads always return a 0. 1h (R/W) = Writing a 1 forces a one-time synchronization pulse to be generated. This event is ORed with the EPWMxSYNCI input of the ePWM module. SWFSYNC is valid (operates) only when EPWMxSYNCI is selected by SYNCOSEL = 00.
5-4	SYNCOSEL	R/W	0h	Synchronization Output Select. These bits select the source of the EPWMxSYNCO signal. 0h (R/W) = EPWMxSYNC: 1h (R/W) = CTR = 0: Time-base counter equal to zero (TBCNT = 0000h) 2h (R/W) = CTR = CMPB : Time-base counter equal to counter-compare B (TBCNT = CMPB) 3h (R/W) = Disable EPWMxSYNCO signal
3	PRDLD	R/W	0h	Active Period Register Load From Shadow Register Select 0h (R/W) = The period register (TBPRD) is loaded from its shadow register when the time-base counter, TBCNT, is equal to zero. A write or read to the TBPRD register accesses the shadow register. 1h (R/W) = Load the TBPRD register immediately without using a shadow register. A write or read to the TBPRD register directly accesses the active register.
2	PHSEN	R/W	0h	Counter Register Load From Phase Register Enable 0h (R/W) = Do not load the time-base counter (TBCNT) from the time-base phase register (TBPHS) 1h (R/W) = Load the time-base counter with the phase register when an EPWMxSYNCI input signal occurs or when a software synchronization is forced by the SWFSYNC bit.
1-0	CTRMODE	R/W	0h	Counter Mode. The time-base counter mode is normally configured once and not changed during normal operation. If you change the mode of the counter, the change will take effect at the next TBCLK edge and the current counter value shall increment or decrement from the value before the mode change. These bits set the time-base counter mode of operation as follows: 0h (R/W) = Up-count mode 1h (R/W) = Down-count mode 2h (R/W) = Up-down-count mode 3h (R/W) = Stop-freeze counter operation (default on reset)

20.2.4.2 TBSTS Register (Offset = 2h) [reset = 0h]

TBSTS is shown in Figure 20-72 and described in Table 20-60.

Return to Summary Table.

Figure 20-72. TBSTS Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	**6**	**5**	**4**	**3**	**2**	**1**	**0**
RESERVED					CTRMAX	SYNCI	CTRDIR
R-0h					0h	W1C-0h	R-0h

Table 20-60. TBSTS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R	0h	
2	CTRMAX		0h	Time-Base Counter Max Latched Status Bit. 0h (R/W) = Reading a 0 indicates the time-base counter never reached its maximum value. Writing a 0 will have no effect. 1h (R/W) = Reading a 1 on this bit indicates that the time-base counter reached the max value 0xFFFF. Writing a 1 to this bit will clear the latched event.
1	SYNCI	W1C	0h	Input Synchronization Latched Status Bit. 0h (R/W) = Writing a 0 will have no effect. Reading a 0 indicates no external synchronization event has occurred. 1h (R/W) = Reading a 1 on this bit indicates that an external synchronization event has occurred (EPWMxSYNCI). Writing a 1 to this bit will clear the latched event.
0	CTRDIR	R	0h	Time-Base Counter Direction Status Bit. At reset, the counter is frozen, therefore, this bit has no meaning. To make this bit meaningful, you must first set the appropriate mode via TBCTL[CTRMODE]. 0h (R/W) = Time-Base Counter is currently counting down. 1h (R/W) = Time-Base Counter is currently counting up.

20.2.4.3 TBPHSHR Register (Offset = 4h) [reset = 0h]

TBPHSHR is shown in Figure 20-73 and described in Table 20-61.

Return to Summary Table.

Figure 20-73. TBPHSHR Register

<table>
<tr><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td></tr>

15-8	TBPHSH	R/W	0h	Time-base phase high-resolution bits
7-0	RESERVED	R	0h	

20.2.4.4 TBPHS Register (Offset = 6h) [reset = 0h]

TBPHS is shown in Figure 20-74 and described in Table 20-62.

Return to Summary Table.

This register is only available on ePWM instances that include the high-resolution PWM (HRPWM) extension, otherwise, this location is reserved.

Figure 20-74. TBPHS Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TBPHS															
R/W-0h															

Table 20-62. TBPHS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	TBPHS	R/W	0h	These bits set time-base counter phase of the selected ePWM relative to the time-base that is supplying the synchronization input signal. (a) If TBCTL[PHSEN] = 0, then the synchronization event is ignored and the time-base counter is not loaded with the phase. (b) If TBCTL[PHSEN] = 1, then the time-base counter (TBCNT) will be loaded with the phase (TBPHS) when a synchronization event occurs. The synchronization event can be initiated by the input synchronization signal (EPWMxSYNCI) or by a software forced synchronization.

20.2.4.5 TBCNT Register (Offset = 8h) [reset = 0h]

TBCNT is shown in Figure 20-75 and described in Table 20-63.

Return to Summary Table.

Figure 20-75. TBCNT Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TBCNT															
R/W-0h															

Table 20-63. TBCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	TBCNT	R/W	0h	Reading these bits gives the current time-base counter value. Writing to these bits sets the current time-base counter value. The update happens as soon as the write occurs. The write is NOT synchronized to the time-base clock (TBCLK) and the register is not shadowed.

20.2.4.6 TBPRD Register (Offset = Ah) [reset = 0h]

TBPRD is shown in Figure 20-76 and described in Table 20-64.

Return to Summary Table.

Figure 20-76. TBPRD Register

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TBPRD															
R/W-0h															

Table 20-64. TBPRD Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	TBPRD	R/W	0h	These bits determine the period of the time-base counter. This sets the PWM frequency. Shadowing of this register is enabled and disabled by the TBCTL[PRDLD] bit. By default this register is shadowed. (a) If TBCTL[PRDLD] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the active register will be loaded from the shadow register when the time-base counter equals zero. (b) If TBCTL[PRDLD] = 1, then the shadow is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. (c) The active and shadow registers share the same memory map address.

20.2.4.7 CMPCTL Register (Offset = Eh) [reset = 0h]

CMPCTL is shown in Figure 20-77 and described in Table 20-65.

Return to Summary Table.

CMPA															
R/W-0h															

Table 20-67. CMPA Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	CMPA	R/W	0h	The value in the active CMPA register is continuously compared to the time-base counter (TBCNT). When the values are equal, the counter-compare module generates a "time-base counter equal to counter compare A" event. This event is sent to the action-qualifier where it is qualified and converted it into one or more actions. These actions can be applied to either the EPWMxA or the EPWMxB output depending on the configuration of the AQCTLA and AQCTLB registers. The actions that can be defined in the AQCTLA and AQCTLB registers include the following. (a) Do nothing the event is ignored. (b) Clear: Pull the EPWMxA and/or EPWMxB signal low. (c) Set: Pull the EPWMxA and/or EPWMxB signal high. (d) Toggle the EPWMxA and/or EPWMxB signal. Shadowing of this register is enabled and disabled by the CMPCTL[SHDWAMODE] bit. By default this register is shadowed. (a) If CMPCTL[SHDWAMODE] = 0, then the shadow is enabled and any write or read will automatically go to the shadow register. In this case, the CMPCTL[LOADAMODE] bit field determines which event will load the active register from the shadow register. (b) Before a write, the CMPCTL[SHDWAFULL] bit can be read to determine if the shadow register is currently full. (c) If CMPCTL[SHDWAMODE] = 1, then the shadow register is disabled and any write or read will go directly to the active register, that is the register actively controlling the hardware. (d) In either mode, the active and shadow registers share the same memory map address.

20.2.4.10 CMPB Register (Offset = 14h) [reset = 0h]

CMPB is shown in Figure 20-80 and described in Table 20-68.

Return to Summary Table.

7	**6**	**5**	**4**	**3**	**2**	**1**	**0**
RESERVED		IN_MODE		POLSEL		OUT_MODE	
R-0h		R/W-0h		R/W-0h		R/W-0h	

Table 20-73. DBCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-6	RESERVED	R	0h	
5-4	IN_MODE	R/W	0h	Dead Band Input Mode Control. Bit 5 controls the S5 switch and bit 4 controls the S4 switch. This allows you to select the input source to the falling-edge and rising-edge delay. To produce classical dead-band waveforms, the default is EPWMxA In is the source for both falling and rising-edge delays. 0h (R/W) = EPWMxA In (from the action-qualifier) is the source for both falling-edge and rising-edge delay. 1h (R/W) = EPWMxB In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxA In (from the action-qualifier) is the source for falling-edge delayed signal. 2h (R/W) = EPWMxA In (from the action-qualifier) is the source for rising-edge delayed signal. EPWMxB In (from the action-qualifier) is the source for falling-edge delayed signal. 3h (R/W) = EPWMxB In (from the action-qualifier) is the source for both rising-edge delay and falling-edge delayed signal.
3-2	POLSEL	R/W	0h	Polarity Select Control. Bit 3 controls the S3 switch and bit 2 controls the S2 switch. This allows you to selectively invert one of the delayed signals before it is sent out of the dead-band submodule. The following descriptions correspond to classical upper/lower switch control as found in one leg of a digital motor control inverter. These assume that DBCTL[OUT_MODE] = 1,1 and DBCTL[IN_MODE] = 0,0. Other enhanced modes are also possible, but not regarded as typical usage modes. 0h (R/W) = Active high (AH) mode. Neither EPWMxA nor EPWMxB is inverted (default). 1h (R/W) = Active low complementary (ALC) mode. EPWMxA is inverted. 2h (R/W) = Active high complementary (AHC). EPWMxB is inverted. 3h (R/W) = Active low (AL) mode. Both EPWMxA and EPWMxB are inverted.

Table 20-73. DBCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1-0	OUT_MODE	R/W	0h	Dead-band Output Mode Control. Bit 1 controls the S1 switch and bit 0 controls the S0 switch. This allows you to selectively enable or bypass the dead-band generation for the falling-edge and rising-edge delay. 0h (R/W) = Dead-band generation is bypassed for both output signals. In this mode, both the EPWMxA and EPWMxB output signals from the action-qualifier are passed directly to the PWM-chopper submodule. In this mode, the POLSEL and IN_MODE bits have no effect. 1h (R/W) = Disable rising-edge delay. The EPWMxA signal from the action-qualifier is passed straight through to the EPWMxA input of the PWM-chopper submodule. The falling-edge delayed signal is seen on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE]. 2h (R/W) = Disable falling-edge delay. The EPWMxB signal from the action-qualifier is passed straight through to the EPWMxB input of the PWM-chopper submodule. The rising-edge delayed signal is seen on output EPWMxA. The input signal for the delay is determined by DBCTL[IN_MODE]. 3h (R/W) = Dead-band is fully enabled for both rising-edge delay on output EPWMxA and falling-edge delay on output EPWMxB. The input signal for the delay is determined by DBCTL[IN_MODE].

20.2.4.16 DBRED Register (Offset = 20h) [reset = 0h]

DBRED is shown in Figure 20-86 and described in Table 20-74.

Return to Summary Table.

Table 20-83. ETPS Register Field Descriptions

Bit	Field	Type	Reset	Description
15-4	RESERVED	R	0h	
3-2	INTCNT	R	0h	ePWM Interrupt Event (EPWMx_INT) Counter Register. These bits indicate how many selected ETSEL[INTSEL] events have occurred. These bits are automatically cleared when an interrupt pulse is generated. If interrupts are disabled, ETSEL[INT] = 0 or the interrupt flag is set, ETFLG[INT] = 1, the counter will stop counting events when it reaches the period value ETPS[INTCNT] = ETPS[INTPRD]. 0h (R/W) = No events have occurred. 1h (R/W) = 1 event has occurred. 2h (R/W) = 2 events have occurred. 3h (R/W) = 3 events have occurred.
1-0	INTPRD	R/W	0h	ePWM Interrupt (EPWMx_INT) Period Select. These bits determine how many selected ETSEL[INTSEL] events need to occur before an interrupt is generated. To be generated, the interrupt must be enabled (ETSEL[INT] = 1). If the interrupt status flag is set from a previous interrupt (ETFLG[INT] = 1) then no interrupt will be generated until the flag is cleared via the ETCLR[INT] bit. This allows for one interrupt to be pending while another is still being serviced. Once the interrupt is generated, the ETPS[INTCNT] bits will automatically be cleared. Writing a INTPRD value that is the same as the current counter value will trigger an interrupt if it is enabled and the status flag is clear. Writing a INTPRD value that is less than the current counter value will result in an undefined state. If a counter event occurs at the same instant as a new zero or non-zero INTPRD value is written, the counter is incremented. 0h (R/W) = Disable the interrupt event counter. No interrupt will be generated and ETFRC[INT] is ignored. 1h (R/W) = Generate an interrupt on the first event INTCNT = 01 (first event) 2h (R/W) = Generate interrupt on ETPS[INTCNT] = 1,0 (second event) 3h (R/W) = Generate interrupt on ETPS[INTCNT] = 1,1 (third event)

3	PULSESEL	R/W	0h	Pulse select bits. Selects which pulse to use for timing events in the HRPWM module. Note: The user needs to select the pulse to match the selection in the EPWM module. If TBPHSHR bus is selected, then CNT_zero pulse should be used. If COMPAHR bus is selected, then it should match the bit setting of the CMPCTL[LOADMODE] bits in the EPWM module as follows. 0: CNT_zero pulse. 1h: PRD_eq pulse. 2h: CNT_zero or PRD_eq (should not use with HRPWM). 3h: No loads (should not use with HRPWM). 0h (R/W) = Select CNT_zero pulse 1h (R/W) = Select PRD_eq pulse
2	DELBUSSEL	R/W	0h	Delay Bus Select Bit: Selects which bus is used to select the delay for the PWM pulse. 0h (R/W) = Select CMPAHR(8) bus from compare module of EPWM (default on reset). 1h (R/W) = Select TBPHSHR(8) bus from time base module.
1-0	DELMODE	R/W	0h	Delay Mode Bits: Selects which edge of the PWM pulse the delay is inserted. Note: When DELMODE = 0,0, the HRCALM[CALMODE] bits are ignored and the delay line is in by-pass mode. Additionally, DLYIN is connected to CALIN and a continuous low value is fed to the delay line to minimize activity in the module. 0h (R/W) = No delay inserted (default on reset) 1h (R/W) = Delay inserted rising edge 2h (R/W) = Delay inserted falling edge 3h (R/W) = Delay inserted on both edges

20.3 Enhanced Capture (eCAP) Module

20.3.1 Introduction

20.3.1.1 Purpose of the Peripheral

Uses for eCAP include:

- Sample rate measurements of audio inputs
- Speed measurements of rotating machinery (for example, toothed sprockets sensed via Hall sensors)
- Elapsed time measurements between position sensor pulses
- Period and duty cycle measurements of pulse train signals
- Decoding current or voltage amplitude derived from duty cycle encoded current/voltage sensors

20.3.1.2 Features

The eCAP module includes the following features:

- 32-bit time base counter
- 4-event time-stamp registers (each 32 bits)
- Edge polarity selection for up to four sequenced time-stamp capture events
- Interrupt on either of the four events
- Single shot capture of up to four event time-stamps
- Continuous mode capture of time-stamps in a four-deep circular buffer
- Absolute time-stamp capture
- Difference (Delta) mode time-stamp capture
- All above resources dedicated to a single input pin
- When not used in capture mode, the ECAP module can be configured as a single channel PWM output

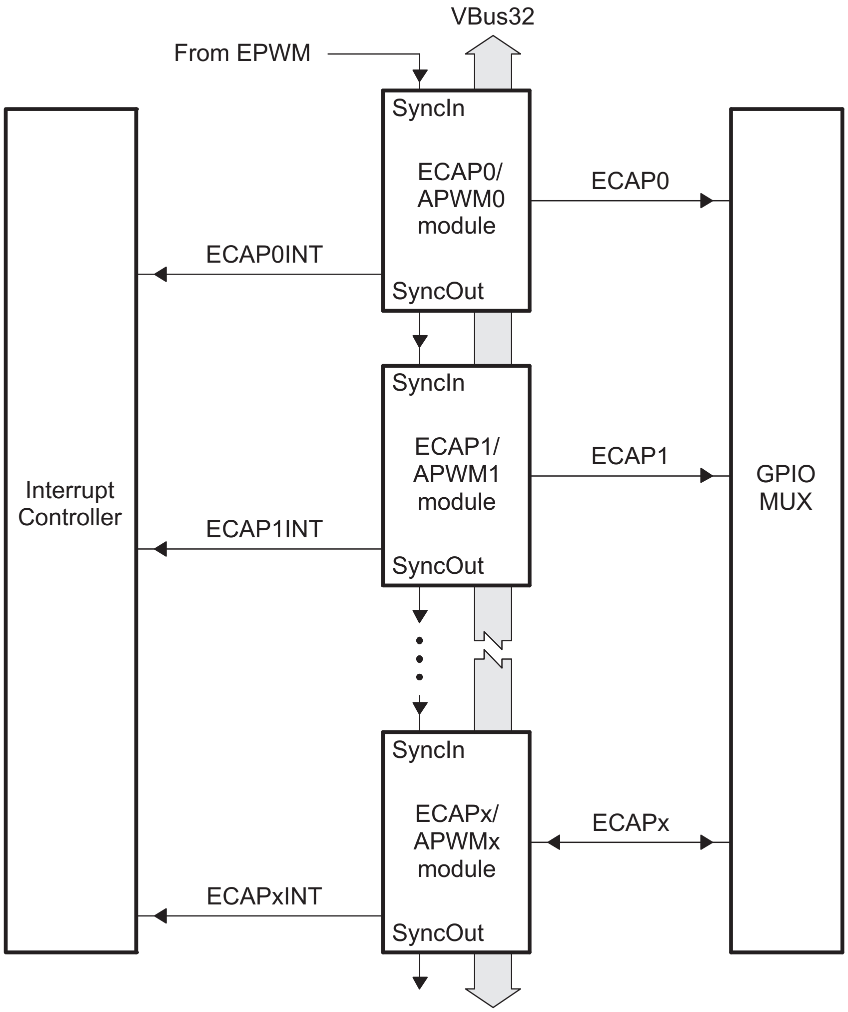
20.3.2 Functional Description

The eCAP module represents one complete capture channel that can be instantiated multiple times depending on the target device. In the context of this guide, one eCAP channel has the following independent key resources:

- Dedicated input capture pin
- 32-bit time base counter
- 4 × 32-bit time-stamp capture registers (CAP1-CAP4)
- 4-stage sequencer (Modulo4 counter) that is synchronized to external events, ECAP pin rising/falling edges.
- Independent edge polarity (rising/falling edge) selection for all 4 events
- Input capture signal prescaling (from 2-62)
- One-shot compare register (2 bits) to freeze captures after 1 to 4 time-stamp events
- Control for continuous time-stamp captures using a 4-deep circular buffer (CAP1-CAP4) scheme
- Interrupt capabilities on any of the 4 capture events

Multiple identical eCAP modules can be contained in a system as shown in Figure 20-101. The number of modules is device-dependent and is based on target application needs. In this chapter, the letter x within a signal or module name is used to indicate a generic eCAP instance on a device.

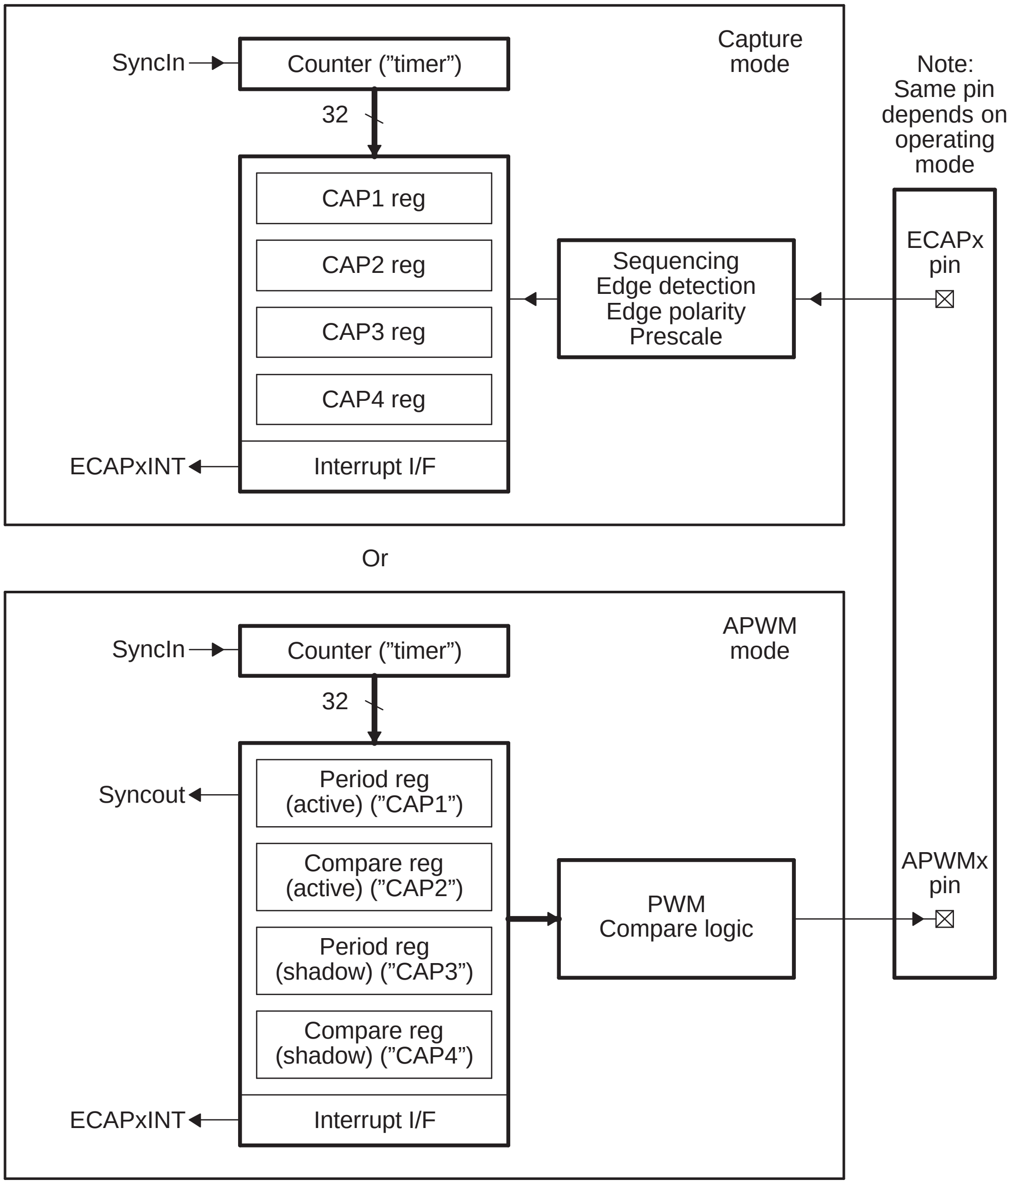
Figure 20-101. Multiple eCAP Modules



20.3.2.1 Capture and APWM Operating Mode

You can use the eCAP module resources to implement a single-channel PWM generator (with 32 bit capabilities) when it is not being used for input captures. The counter operates in count-up mode, providing a time-base for asymmetrical pulse width modulation (PWM) waveforms. The CAP1 and CAP2 registers become the active period and compare registers, respectively, while CAP3 and CAP4 registers become the period and capture shadow registers, respectively. Figure 20-102 is a high-level view of both the capture and auxiliary pulse-width modulator (APWM) modes of operation.

Figure 20-102. Capture and APWM Modes of Operation



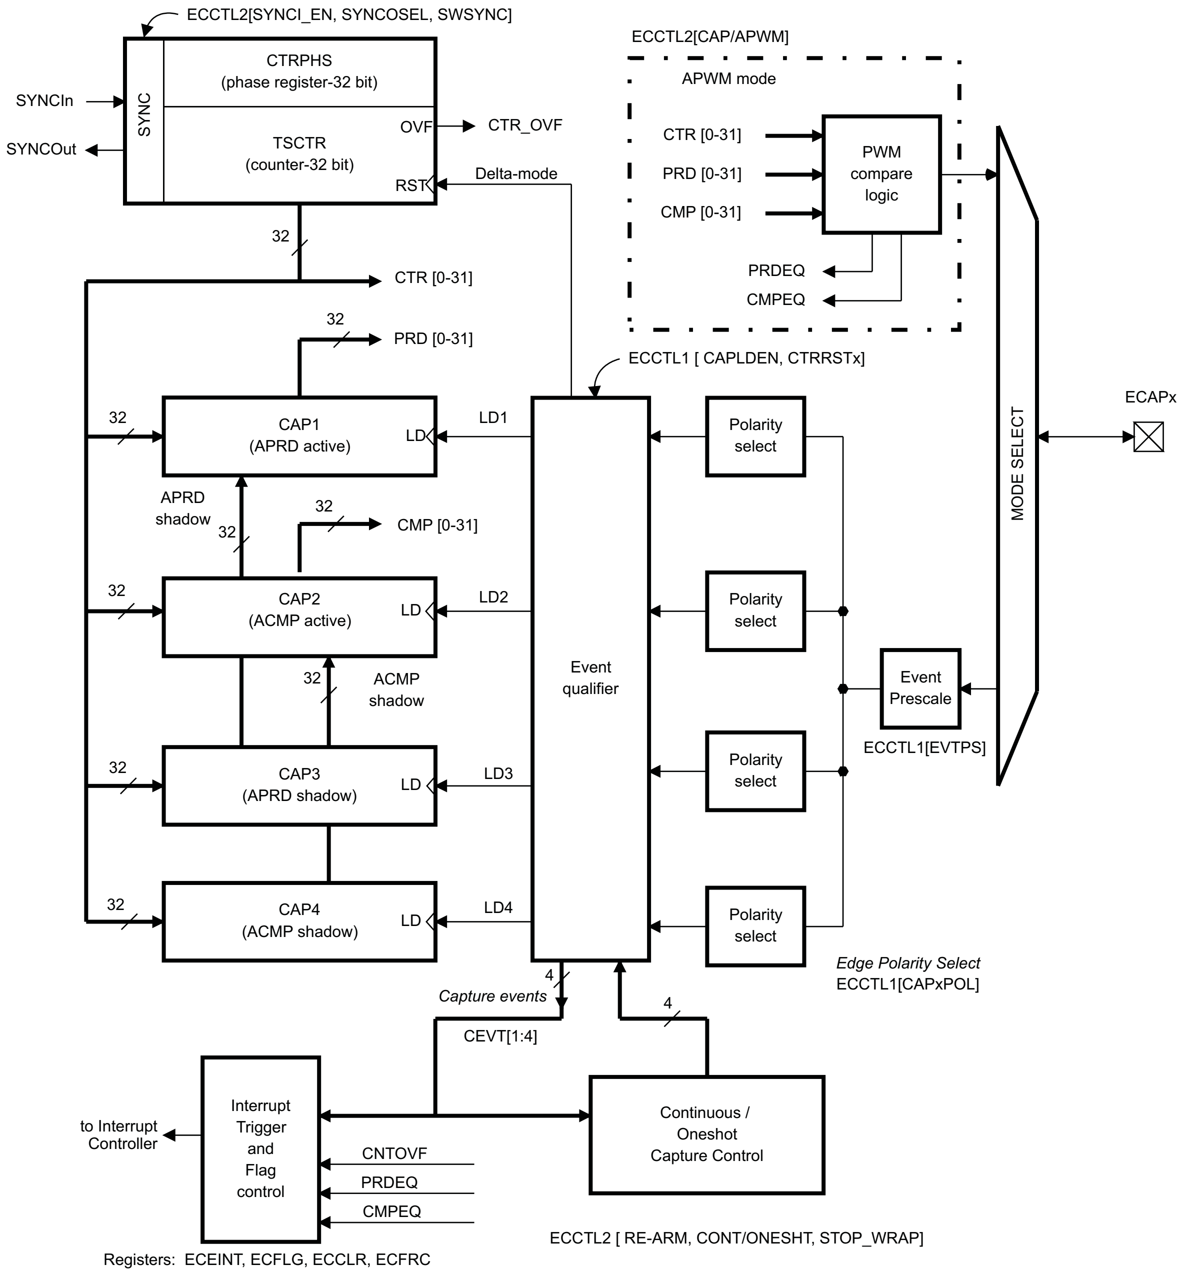
(1) A single pin is shared between CAP and APWM functions. In capture mode, it is an input; in APWM mode, it is an output.

(2) In APWM mode, writing any value to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

20.3.2.2 Capture Mode Description

Figure 20-103 shows the various components that implement the capture function.

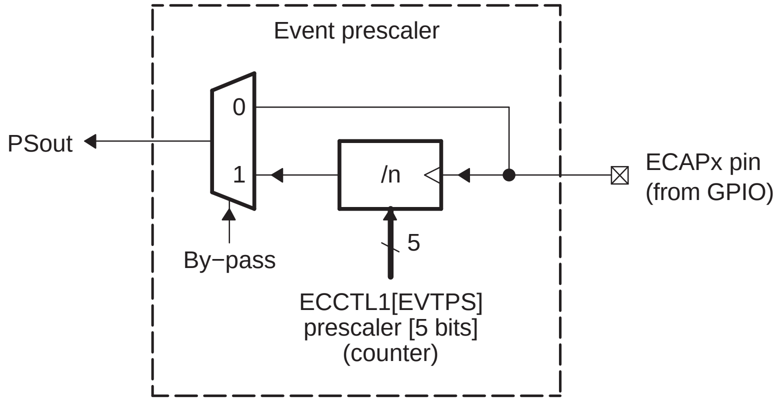
Figure 20-103. Capture Function Diagram



20.3.2.2.1 Event Prescaler

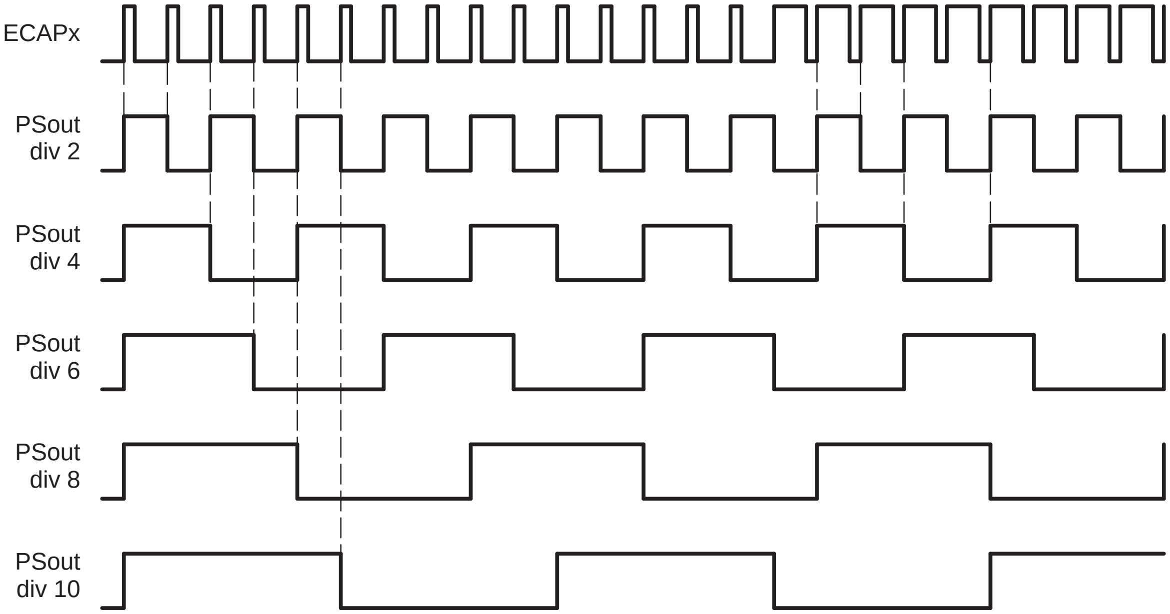
An input capture signal (pulse train) can be prescaled by N = 2-62 (in multiples of 2) or can bypass the prescaler. This is useful when very high frequency signals are used as inputs. Figure 20-104 shows a functional diagram and Figure 20-105 shows the operation of the prescale function.

Figure 20-104. Event Prescale Control



(1) When a prescale value of 1 is chosen (ECCTL1[13:9] = 0000) the input capture signal by-passes the prescale logic completely.

Figure 20-105. Prescale Function Waveforms



20.3.2.2.2 Edge Polarity Select and Qualifier

- Four independent edge polarity (rising edge/falling edge) selection multiplexers are used, one for each capture event.
- Each edge (up to 4) is event qualified by the Modulo4 sequencer.
- The edge event is gated to its respective CAP*n* register by the Mod4 counter. The CAP*n* register is loaded on the falling edge.

20.3.2.2.3 Continuous/One-Shot Control

- The Mod4 (2 bit) counter is incremented via edge qualified events (CEVT1-CEVT4).
- The Mod4 counter continues counting (0->1->2->3->0) and wraps around unless stopped.
- A 2-bit stop register is used to compare the Mod4 counter output, and when equal stops the Mod4 counter and inhibits further loads of the CAP1-CAP4 registers. This occurs during one-shot operation.

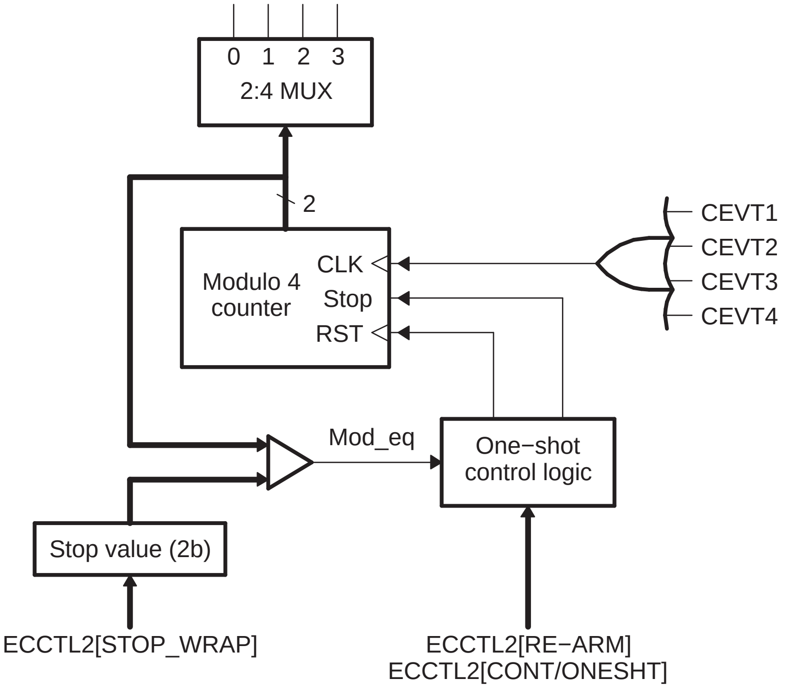
The continuous/one-shot block (Figure 20-106) controls the start/stop and reset (zero) functions of the Mod4 counter via a mono-shot type of action that can be triggered by the stop-value comparator and re-armed via software control.

Once armed, the eCAP module waits for 1-4 (defined by stop-value) capture events before freezing both the Mod4 counter and contents of CAP1-4 registers (time-stamps).

Re-arming prepares the eCAP module for another capture sequence. Also re-arming clears (to zero) the Mod4 counter and permits loading of CAP1-4 registers again, providing the CAPLDEN bit is set.

In continuous mode, the Mod4 counter continues to run (0->1->2->3->0, the one-shot action is ignored, and capture values continue to be written to CAP1-4 in a circular buffer sequence.

Figure 20-106. Continuous/One-shot Block Diagram



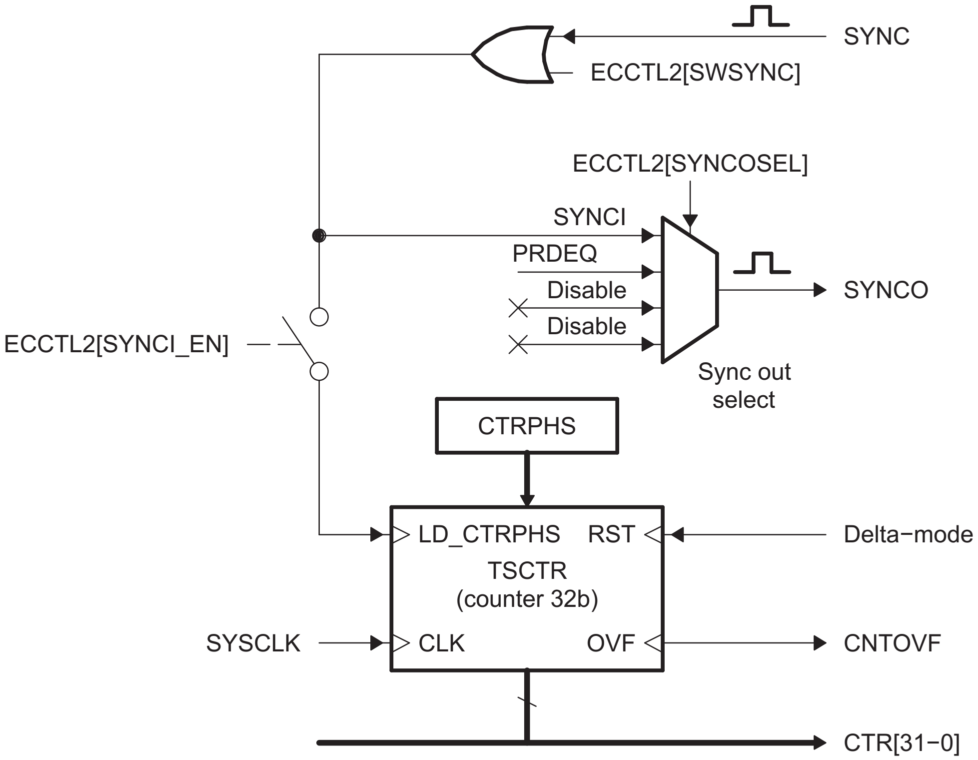
20.3.2.2.4 32-Bit Counter and Phase Control

This counter (Figure 20-107) provides the time-base for event captures, and is clocked via the system clock.

A phase register is provided to achieve synchronization with other counters, via a hardware and software forced sync. This is useful in APWM mode when a phase offset between modules is needed.

On any of the four event loads, an option to reset the 32-bit counter is given. This is useful for time difference capture. The 32-bit counter value is captured first, then it is reset to 0 by any of the LD1-LD4 signals.

Figure 20-107. Counter and Synchronization Block Diagram



20.3.2.2.5 CAP1-CAP4 Registers

These 32-bit registers are fed by the 32-bit counter timer bus, CTR[0-31] and are loaded (capture a time-stamp) when their respective LD inputs are strobed.

Loading of the capture registers can be inhibited via control bit CAPLDEN. During one-shot operation, this bit is cleared (loading is inhibited) automatically when a stop condition occurs, StopValue = Mod4.

CAP1 and CAP2 registers become the active period and compare registers, respectively, in APWM mode.

CAP3 and CAP4 registers become the respective shadow registers (APRD and ACMP) for CAP1 and CAP2 during APWM operation.

20.3.2.2.6 Interrupt Control

An Interrupt can be generated on capture events (CEVT1-CEVT4, CNTOVF) or APWM events (PRDEQ, CMPEQ). See Figure 20-108.

A counter overflow event (FFFF FFFFh->0000 0000h) is also provided as an interrupt source (CNTOVF).

The capture events are edge and sequencer qualified (that is, ordered in time) by the polarity select and Mod4 gating, respectively.

One of these events can be selected as the interrupt source (from the eCAP*n* module) going to the interrupt controller.

Seven interrupt events (CEVT1, CEVT2, CEVT3, CEVT4, CNTOVF, PRDEQ, CMPEQ) can be generated. The interrupt enable register (ECEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (ECFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated to the interrupt controller only if any of the interrupt events are enabled, the flag bit is 1, and the INT flag bit is 0. The interrupt service routine must clear the global interrupt flag bit and the serviced event via the interrupt clear register (ECCLR) before any other interrupt pulses are generated. You can force an interrupt event via the interrupt force register (ECFRC). This is useful for test purposes.

Note that the interrupts coming from the eCAP module are also used as DMA events. The interrupt registers should be used to enable and clear the current DMA event in order for the eCAP module to generate subsequent DMA events.

20.3.2.2.7 Shadow Load and Lockout Control

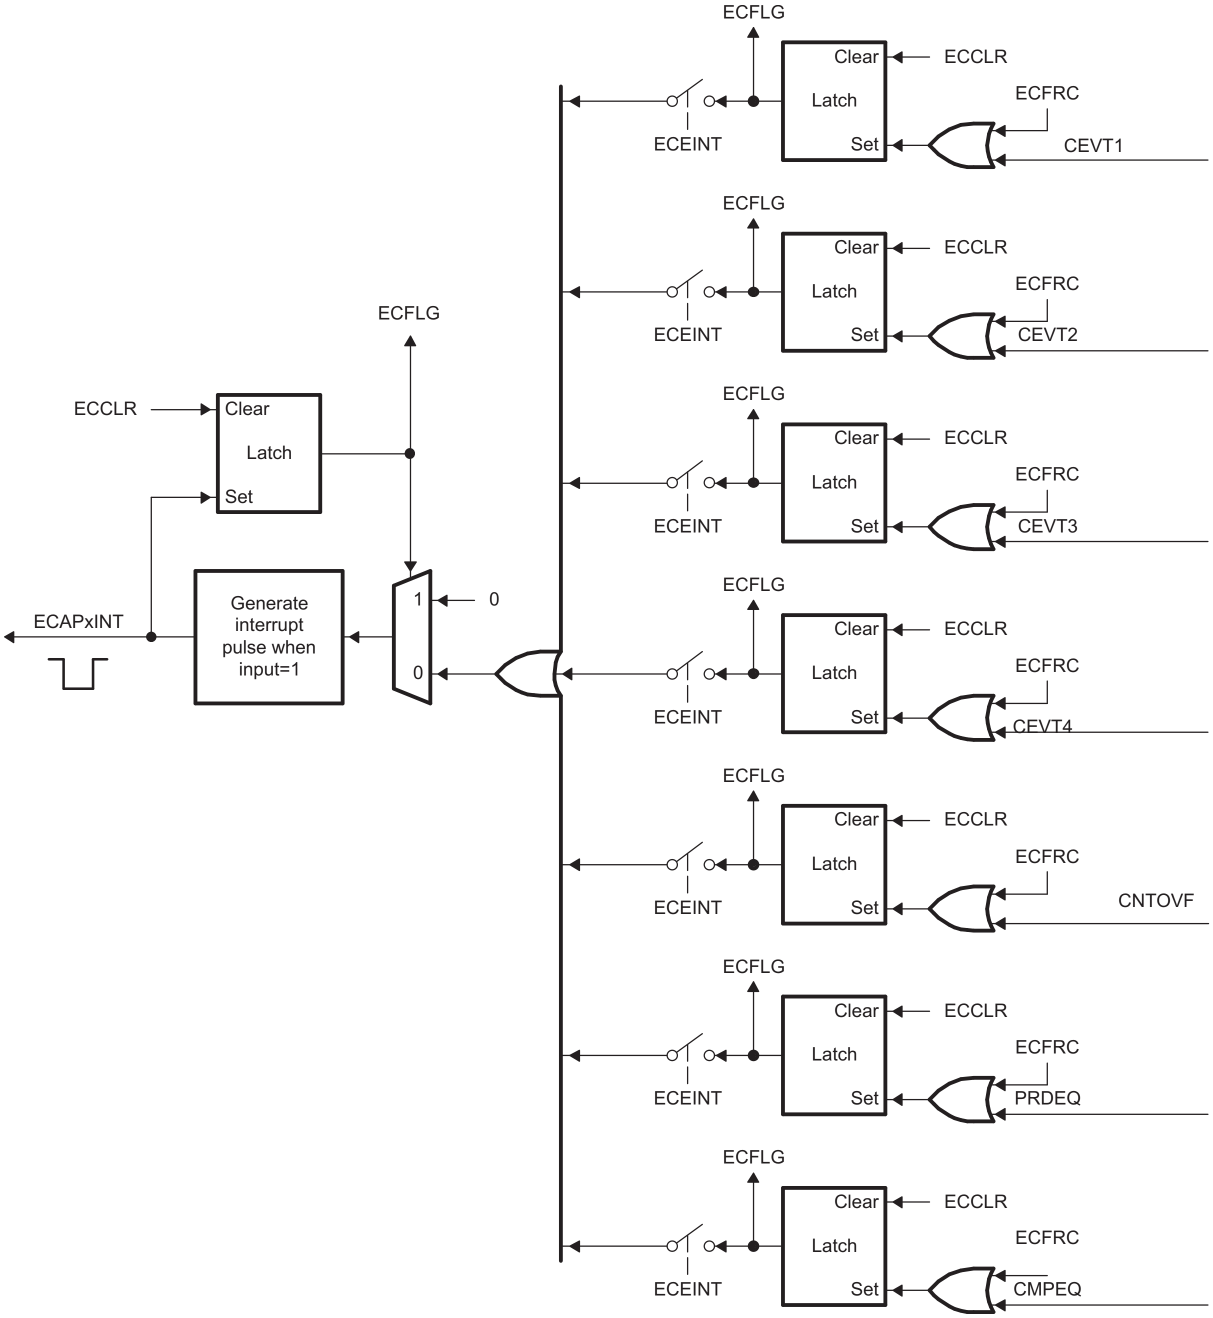
In capture mode, this logic inhibits (locks out) any shadow loading of CAP1 or CAP2 from APRD and ACMP registers, respectively.

In APWM mode, shadow loading is active and two choices are permitted:

- Immediate - APRD or ACMP are transferred to CAP1 or CAP2 immediately upon writing a new value.
- On period equal, CTR[31:0] = PRD[31:0]

NOTE: The CEVT1, CEVT2, CEVT3, CEVT4 flags are only active in capture mode (ECCTL2[CAP/APWM == 0]). The PRDEQ, CMPEQ flags are only valid in APWM mode (ECCTL2[CAP/APWM == 1]). CNTOVF flag is valid in both modes.

Figure 20-108. Interrupts in eCAP Module

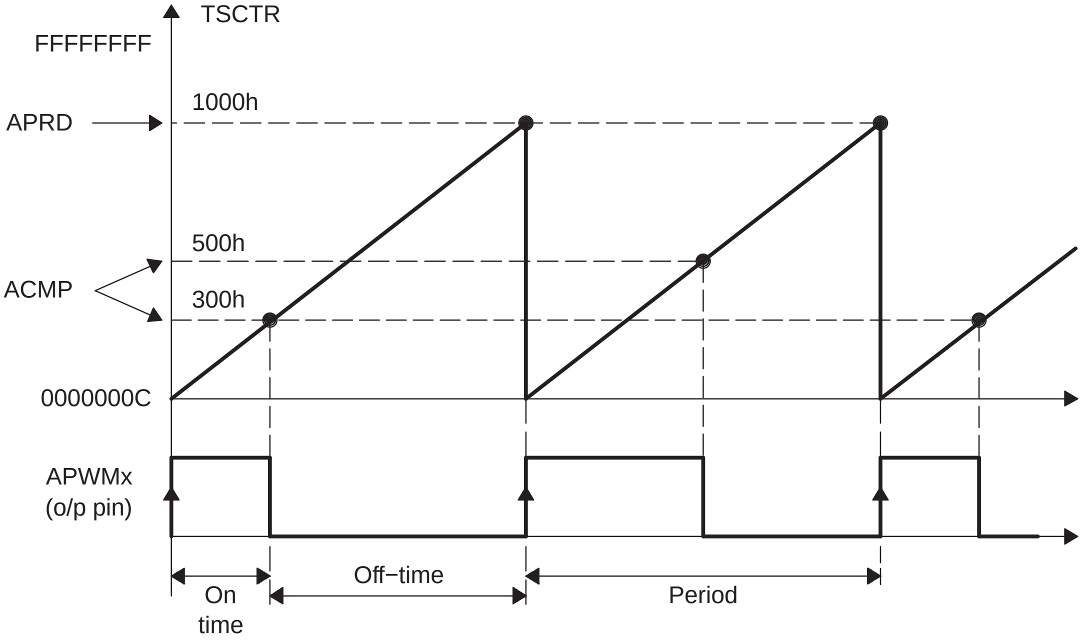


20.3.2.2.8 APWM Mode Operation

Main operating highlights of the APWM section:

- The time-stamp counter bus is made available for comparison via 2 digital (32-bit) comparators.
- When CAP1/2 registers are not used in capture mode, their contents can be used as Period and Compare values in APWM mode.
- Double buffering is achieved via shadow registers APRD and ACMP (CAP3/4). The shadow register contents are transferred over to CAP1/2 registers either immediately upon a write, or on a PRDEQ trigger.
- In APWM mode, writing to CAP1/CAP2 active registers will also write the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 will invoke the shadow mode.
- During initialization, you must write to the active registers for both period and compare. This automatically copies the initial values into the shadow values. For subsequent compare updates, during run-time, you only need to use the shadow registers.

Figure 20-109. PWM Waveform Details Of APWM Mode Operation



The behavior of APWM active-high mode (APWMPOL == 0) is:

```
CMP = 0x00000000, output low for duration of period (0% duty)
CMP = 0x00000001, output high 1 cycle
CMP = 0x00000002, output high 2 cycles
CMP = PERIOD, output high except for 1 cycle (<100% duty)
CMP = PERIOD+1, output high for complete period (100% duty)
CMP > PERIOD+1, output high for complete period
```

The behavior of APWM active-low mode (APWMPOL == 1) is:

```
CMP = 0x00000000, output high for duration of period (0% duty)
CMP = 0x00000001, output low 1 cycle
CMP = 0x00000002, output low 2 cycles
CMP = PERIOD, output low except for 1 cycle (<100% duty)
CMP = PERIOD+1, output low for complete period (100% duty)
CMP > PERIOD+1, output low for complete period
```

20.3.3 Use Cases

The following sections will provide Applications examples and code snippets to show how to configure and operate the eCAP module. For clarity and ease of use, below are useful #defines which will help in the understanding of the examples.

```
// ECCTL1 ( ECAP Control Reg 1)
//==========================
// CAPxPOL bits
#define    EC_RISING              0x0
#define    EC_FALLING             0x1

// CTRRSTx bits
#define    EC_ABS_MODE            0x0
#define    EC_DELTA_MODE          0x1

// PRESCALE bits
#define    EC_BYPASS              0x0
#define    EC_DIV1                0x0
#define    EC_DIV2                0x1
#define    EC_DIV4                0x2
#define    EC_DIV6                0x3
#define    EC_DIV8                0x4
#define    EC_DIV10               0x5

// ECCTL2 ( ECAP Control Reg 2)
//==========================
// CONT/ONESHOT bit
#define    EC_CONTINUOUS          0x0
#define    EC_ONESHOT             0x1

// STOPVALUE bit
#define    EC_EVENT1              0x0
#define    EC_EVENT2              0x1
#define    EC_EVENT3              0x2
#define    EC_EVENT4              0x3

// RE-ARM bit
#define    EC_ARM                 0x1

// TSCTRSTOP bit
#define    EC_FREEZE              0x0
#define    EC_RUN                 0x1

// SYNCO_SEL bit
#define    EC_SYNCIN              0x0
#define    EC_CTR_PRD             0x1
#define    EC_SYNCO_DIS           0x2

// CAP/APWM mode bit
#define    EC_CAP_MODE            0x0
#define    EC_APWM_MODE           0x1

// APWMPOL bit
#define    EC_ACTV_HI             0x0
#define    EC_ACTV_LO             0x1

// Generic
#define    EC_DISABLE             0x0
#define    EC_ENABLE              0x1
#define    EC_FORCE               0x1
```

20.3.3.1 Absolute Time-Stamp Operation Rising Edge Trigger Example

Figure 20-110 shows an example of continuous capture operation (Mod4 counter wraps around). In this figure, TSCTR counts-up without resetting and capture events are qualified on the rising edge only, this gives period (and frequency) information.

On an event, the TSCTR contents (time-stamp) is first captured, then Mod4 counter is incremented to the next state. When the TSCTR reaches FFFF FFFFh (maximum value), it wraps around to 0000 0000h (not shown in Figure 20-110), if this occurs, the CNTOVF (counter overflow) flag is set, and an interrupt (if enabled) occurs, CNTOVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. Captured time-stamps are valid at the point indicated by the diagram, after the 4th event, hence event CEVT4 can conveniently be used to trigger an interrupt and the CPU can read data from the CAP*n* registers.

Figure 20-110. Capture Sequence for Absolute Time-Stamp, Rising Edge Detect

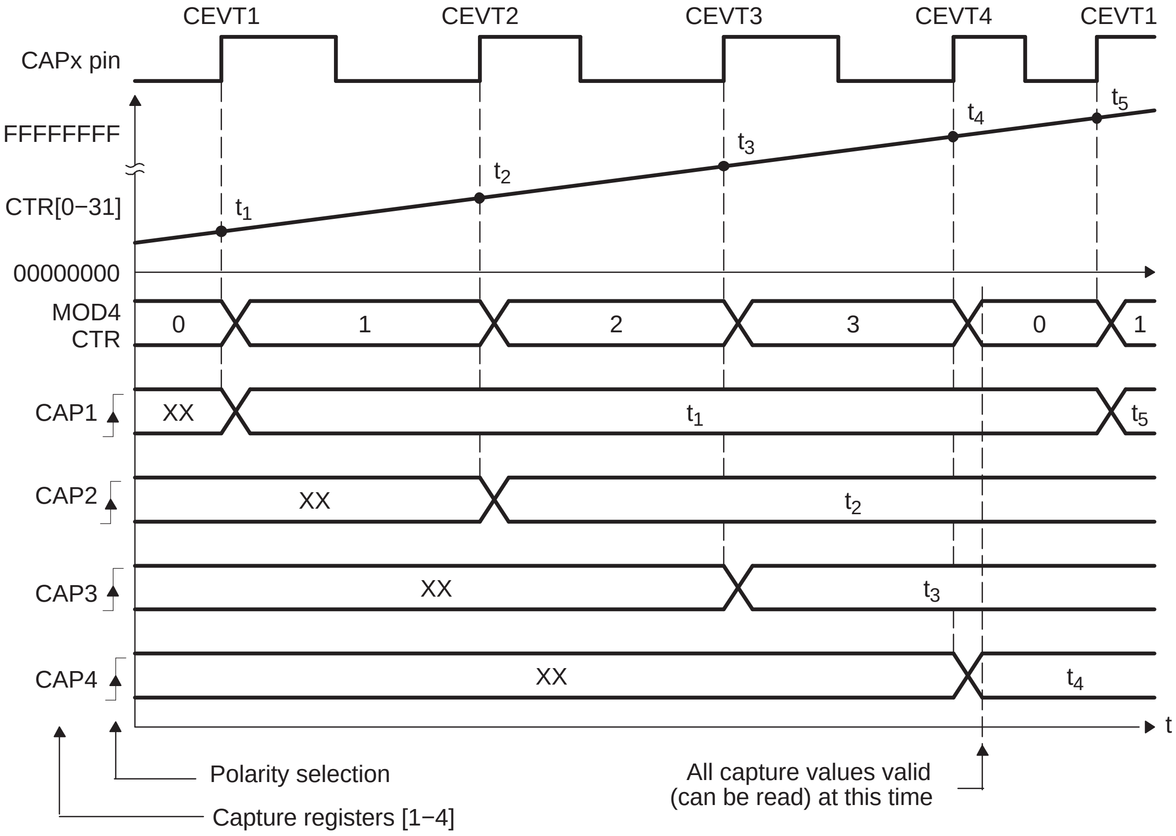


Table 20-89. ECAP Initialization for CAP Mode Absolute Time, Rising Edge Trigger

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_RISING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_RISING
ECCTL1	CTRRST1	EC_ABS_MODE
ECCTL1	CTRRST2	EC_ABS_MODE
ECCTL1	CTRRST3	EC_ABS_MODE
ECCTL1	CTRRST4	EC_ABS_MODE
ECCTL1	CAPLDEN	EC_ENABLE

ECCTL2	SYNCI_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

Example 20-9. Code Snippet for CAP Mode Absolute Time, Rising Edge Trigger

```
// Code snippet for CAP mode Absolute Time, Rising edge trigger

// Run Time ( e.g. CEVT4 triggered ISR call)
//==========================================
    TSt1 = ECAPxRegs.CAP1;        // Fetch Time-Stamp captured at t1
    TSt2 = ECAPxRegs.CAP2;        // Fetch Time-Stamp captured at t2
    TSt3 = ECAPxRegs.CAP3;        // Fetch Time-Stamp captured at t3
    TSt4 = ECAPxRegs.CAP4;        // Fetch Time-Stamp captured at t4

    Period1 = TSt2-TSt1;        // Calculate 1st period
    Period2 = TSt3-TSt2;        // Calculate 2nd period
    Period3 = TSt4-TSt3;        // Calculate 3rd period
```

20.3.3.2 Absolute Time-Stamp Operation Rising and Falling Edge Trigger Example

In Figure 20-111 the eCAP operating mode is almost the same as in the previous section except capture events are qualified as either rising or falling edge, this now gives both period and duty cycle information: Period1 = $t_3 - t_1$, Period2 = $t_5 - t_3$, …etc. Duty Cycle1 (on-time %) = ($t_2 - t_1$) / Period1 x 100%, etc. Duty Cycle1 (off-time %) = ($t_3 - t_2$) / Period1 x 100%, etc.

Figure 20-111. Capture Sequence for Absolute Time-Stamp, Rising and Falling Edge Detect

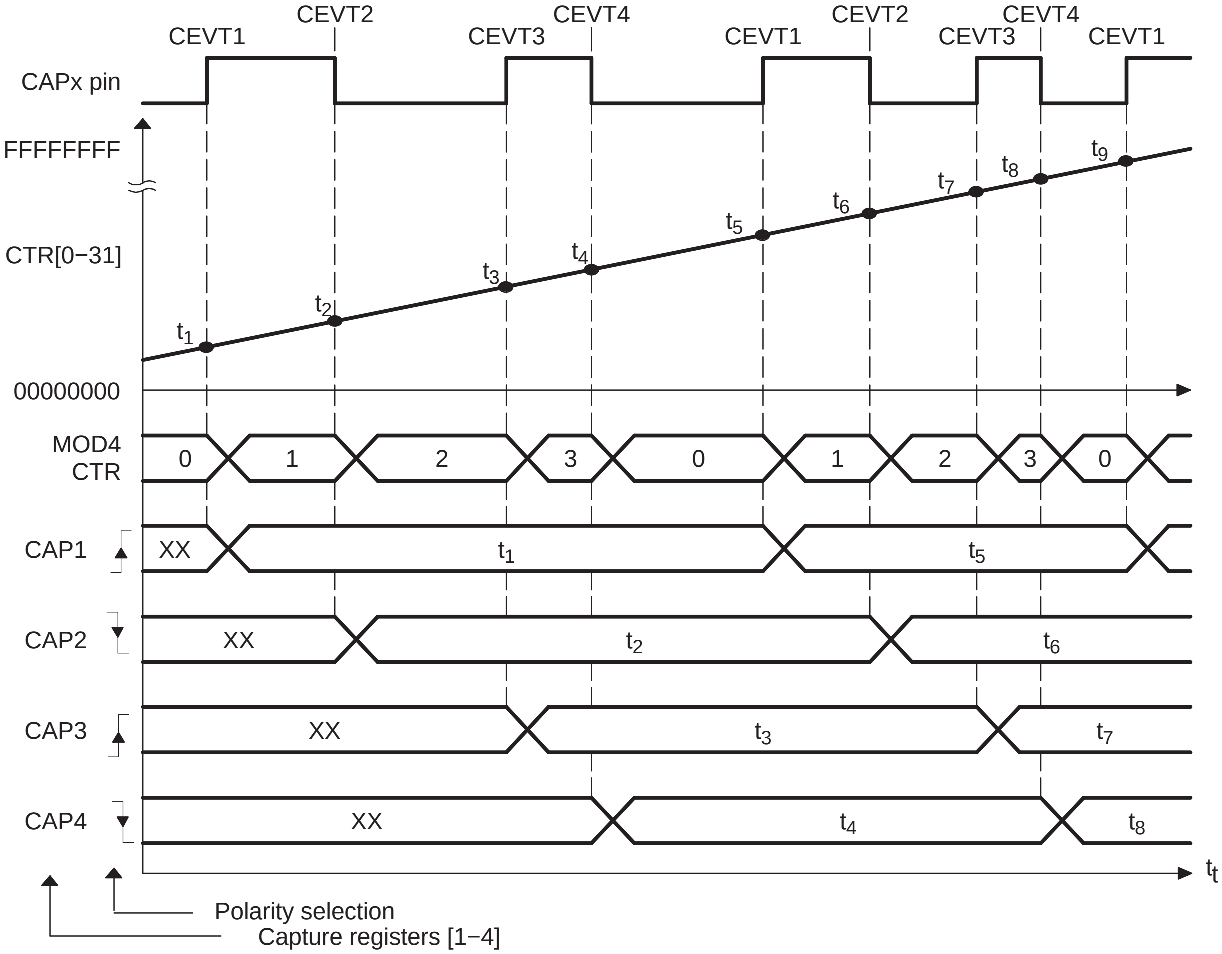

Table 20-90. ECAP Initialization for CAP Mode Absolute Time, Rising and Falling Edge Trigger

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_FALLING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_FALLING
ECCTL1	CTRRST1	EC_ABS_MODE
ECCTL1	CTRRST2	EC_ABS_MODE
ECCTL1	CTRRST3	EC_ABS_MODE
ECCTL1	CTRRST4	EC_ABS_MODE
ECCTL1	CAPLDEN	EC_ENABLE
ECCTL1	PRESCALE	EC_DIV1
ECCTL2	CAP_APWM	EC_CAP_MODE
ECCTL2	CONT_ONESHT	EC_CONTINUOUS
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	SYNCI_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

Example 20-10. Code Snippet for CAP Mode Absolute Time, Rising and Falling Edge Trigger

```
// Code snippet for CAP mode Absolute Time, Rising & Falling edge triggers

// Run Time ( e.g. CEVT4 triggered ISR call)
//==========================================
    TSt1 = ECAPxRegs.CAP1;        // Fetch Time-Stamp captured at t1
    TSt2 = ECAPxRegs.CAP2;        // Fetch Time-Stamp captured at t2
    TSt3 = ECAPxRegs.CAP3;        // Fetch Time-Stamp captured at t3
    TSt4 = ECAPxRegs.CAP4;        // Fetch Time-Stamp captured at t4

    Period1 = TSt3-TSt1;        // Calculate 1st period
    DutyOnTime1 = TSt2-TSt1;    // Calculate On time
    DutyOffTime1 = TSt3-TSt2;    // Calculate Off time
```

20.3.3.3 Time Difference (Delta) Operation Rising Edge Trigger Example

Figure 20-112 shows how the eCAP module can be used to collect Delta timing data from pulse train waveforms. Here Continuous Capture mode (TSCTR counts-up without resetting, and Mod4 counter wraps around) is used. In Delta-time mode, TSCTR is Reset back to Zero on every valid event. Here Capture events are qualified as Rising edge only. On an event, TSCTR contents (time-stamp) is captured first, and then TSCTR is reset to Zero. The Mod4 counter then increments to the next state. If TSCTR reaches FFFF FFFFh (maximum value), before the next event, it wraps around to 0000 0000h and continues, a CNTOVF (counter overflow) Flag is set, and an Interrupt (if enabled) occurs. The advantage of Delta-time Mode is that the CAP*n* contents directly give timing data without the need for CPU calculations: Period1 = T_1, Period2 = T_2,…etc. As shown in Figure 20-112, the CEVT1 event is a good trigger point to read the timing data, T_1, T_2, T_3, T_4 are all valid here.

Figure 20-112. Capture Sequence for Delta Mode Time-Stamp, Rising Edge Detect

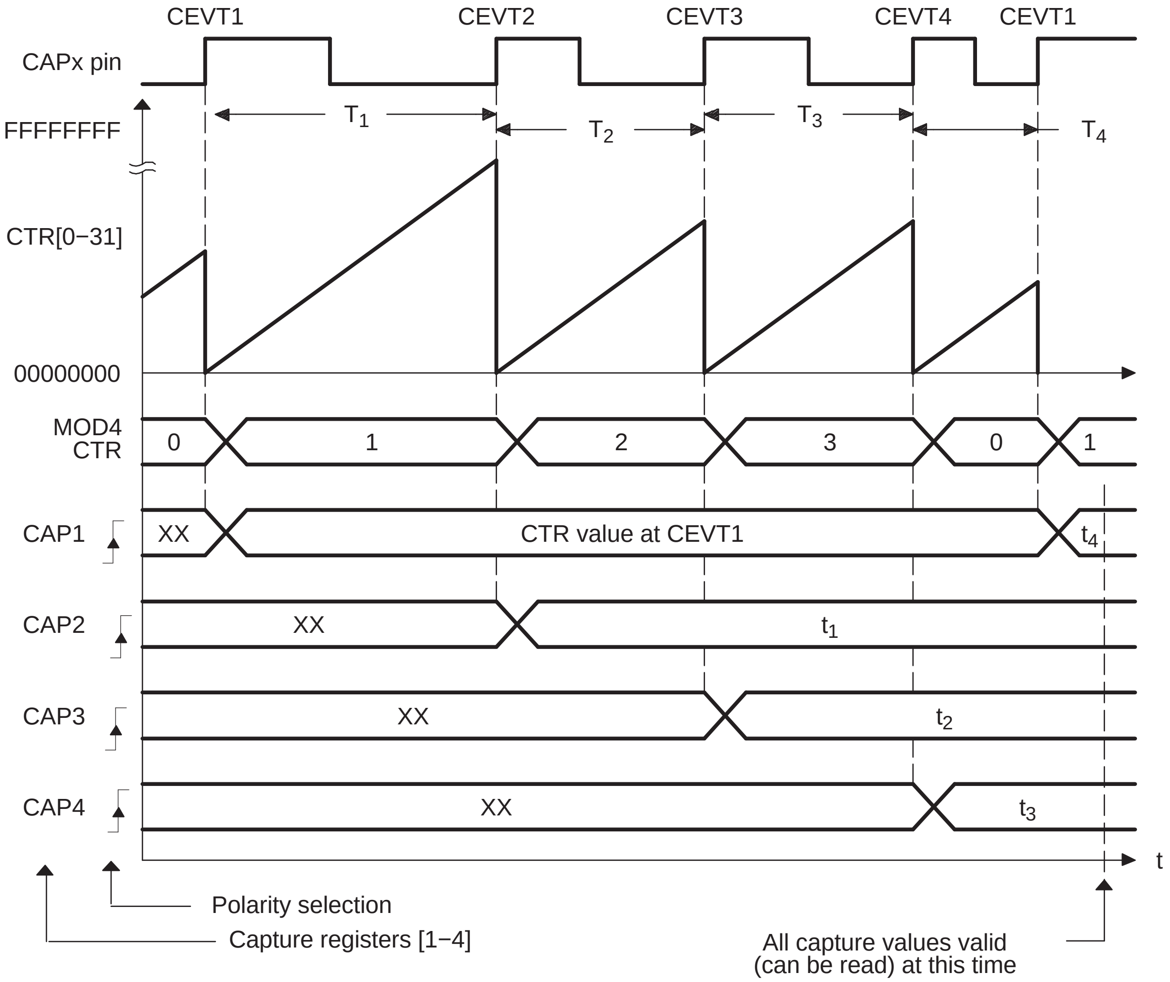

Table 20-91. ECAP Initialization for CAP Mode Delta Time, Rising Edge Trigger

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_RISING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_RISING
ECCTL1	CTRRST1	EC_DELTA_MODE
ECCTL1	CTRRST2	EC_DELTA_MODE
ECCTL1	CTRRST3	EC_DELTA_MODE
ECCTL1	CTRRST4	EC_DELTA_MODE
ECCTL1	CAPLDEN	EC_ENABLE
ECCTL1	PRESCALE	EC_DIV1
ECCTL2	CAP_APWM	EC_CAP_MODE
ECCTL2	CONT_ONESHT	EC_CONTINUOUS
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	SYNCI_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

Example 20-11. Code Snippet for CAP Mode Delta Time, Rising Edge Trigger

```
// Code snippet for CAP mode Delta Time, Rising edge trigger

// Run Time ( e.g. CEVT1 triggered ISR call)
//==========================================
// Note: here Time-stamp directly represents the Period value.
    Period4 = ECAPxRegs.CAP1;    // Fetch Time-Stamp captured at T1
    Period1 = ECAPxRegs.CAP2;    // Fetch Time-Stamp captured at T2
    Period2 = ECAPxRegs.CAP3;    // Fetch Time-Stamp captured at T3
    Period3 = ECAPxRegs.CAP4;    // Fetch Time-Stamp captured at T4
```

20.3.3.4 Time Difference (Delta) Operation Rising and Falling Edge Trigger Example

In Figure 20-113 the eCAP operating mode is almost the same as in previous section except Capture events are qualified as either Rising or Falling edge, this now gives both Period and Duty cycle information: Period1 = $T_1 + T_2$, Period2 = $T_3 + T_4$, …etc Duty Cycle1 (on-time %) = T_1 / Period1 × 100%, etc Duty Cycle1 (off-time %) = T_2 / Period1 × 100%, etc

During initialization, you must write to the active registers for both period and compare. This will then automatically copy the init values into the shadow values. For subsequent compare updates, that is, during run-time, only the shadow registers must be used.

Figure 20-113. Capture Sequence for Delta Mode Time-Stamp, Rising and Falling Edge Detect

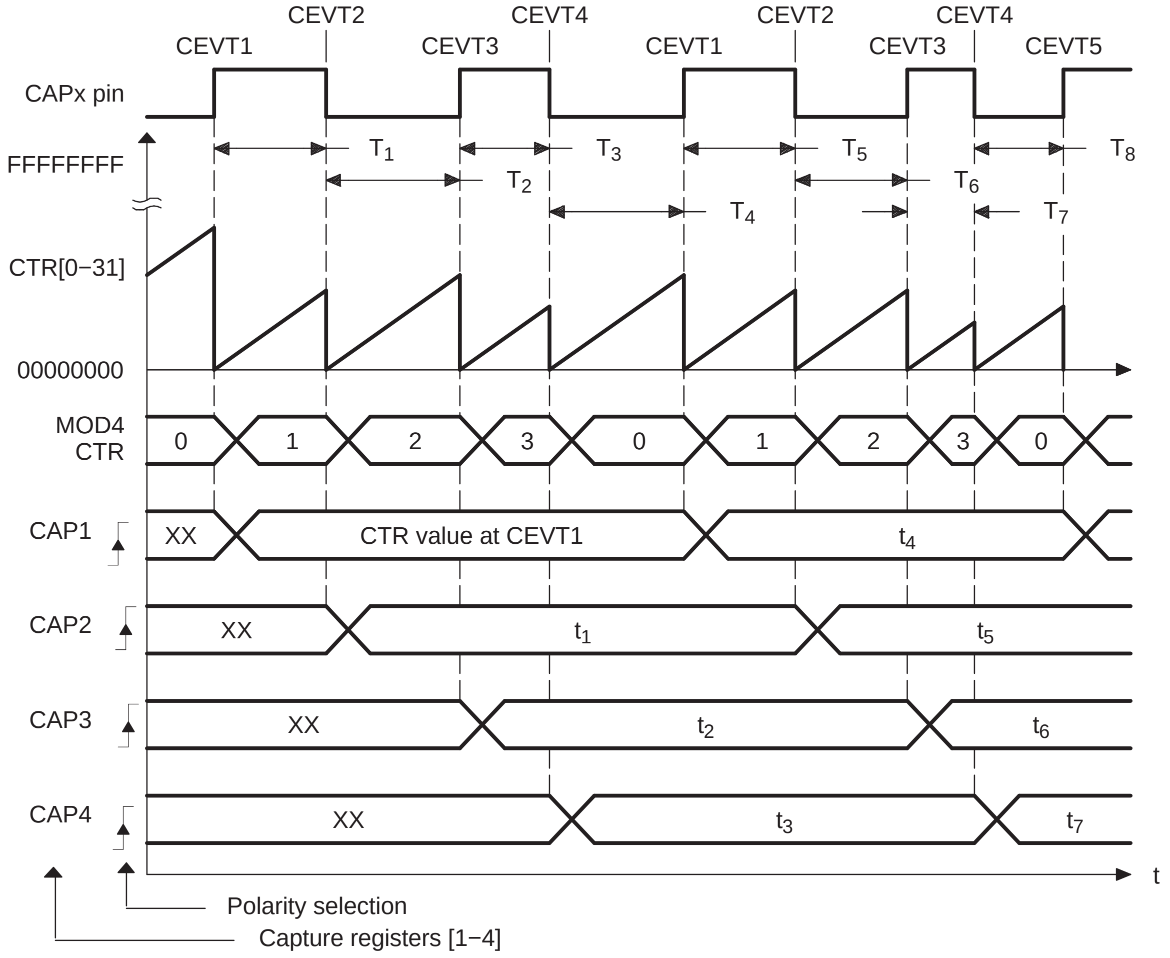

Table 20-92. ECAP Initialization for CAP Mode Delta Time, Rising and Falling Edge Triggers

Register	Bit	Value
ECCTL1	CAP1POL	EC_RISING
ECCTL1	CAP2POL	EC_FALLING
ECCTL1	CAP3POL	EC_RISING
ECCTL1	CAP4POL	EC_FALLING
ECCTL1	CTRRST1	EC_DELTA_MODE
ECCTL1	CTRRST2	EC_DELTA_MODE
ECCTL1	CTRRST3	EC_DELTA_MODE
ECCTL1	CTRRST4	EC_DELTA_MODE
ECCTL1	CAPLDEN	EC_ENABLE
ECCTL1	PRESCALE	EC_DIV1
ECCTL2	CAP_APWM	EC_CAP_MODE
ECCTL2	CONT_ONESHT	EC_CONTINUOUS
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	SYNCI_EN	EC_DISABLE
ECCTL2	TSCTRSTOP	EC_RUN

Example 20-12. Code Snippet for CAP Mode Delta Time, Rising and Falling Edge Triggers

```
// Code snippet for CAP mode Delta Time, Rising and Falling edge triggers

// Run Time ( e.g. CEVT1 triggered ISR call)
//==========================================
// Note: here Time-stamp directly represents the Duty cycle values.
    DutyOnTime1 =  ECAPxRegs.CAP2;    // Fetch Time-Stamp captured at T2
    DutyOffTime1 = ECAPxRegs.CAP3;    // Fetch Time-Stamp captured at T3
    DutyOnTime2 =  ECAPxRegs.CAP4;    // Fetch Time-Stamp captured at T4
    DutyOffTime2 = ECAPxRegs.CAP1;    // Fetch Time-Stamp captured at T1

    Period1 = DutyOnTime1 + DutyOffTime1;
    Period2 = DutyOnTime2 + DutyOffTime2;
```

20.3.3.5 Application of the APWM Mode

20.3.3.5.1 Simple PWM Generation (Independent Channel/s) Example

In this example, the eCAP module is configured to operate as a PWM generator. Here a very simple single channel PWM waveform is generated from output pin APWM*n*. The PWM polarity is active high, which means that the compare value (CAP2 reg is now a compare register) represents the on-time (high level) of the period. Alternatively, if the APWMPOL bit is configured for active low, then the compare value represents the off-time.

Figure 20-114. PWM Waveform Details of APWM Mode Operation

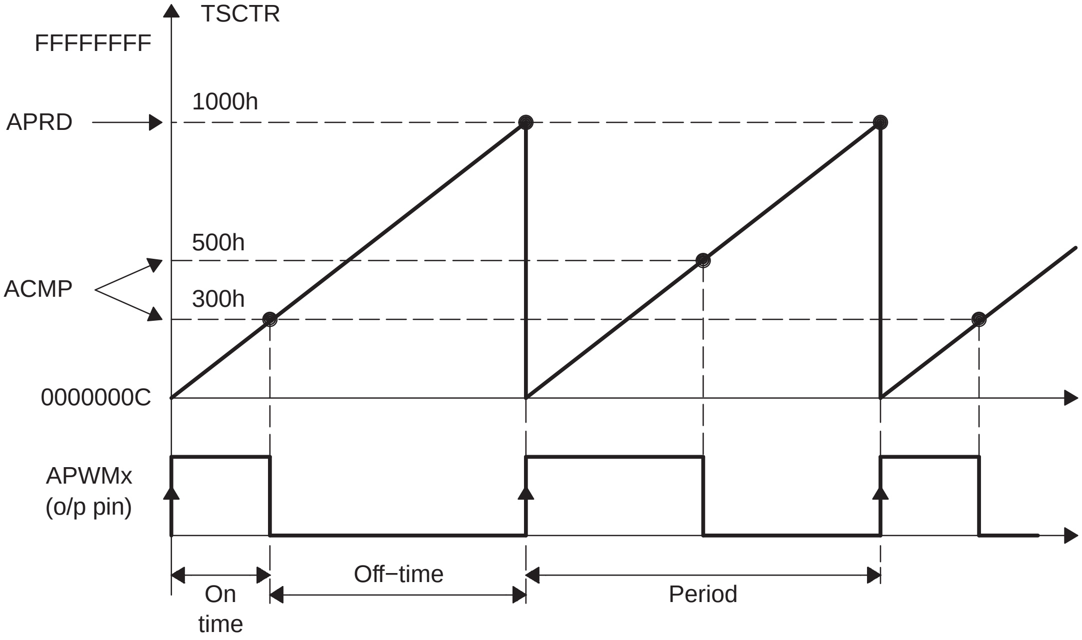

Table 20-93. ECAP Initialization for APWM Mode

Register	Bit	Value
CAP1	CAP1	0x1000
CTRPHS	CTRPHS	0x0
ECCTL2	CAP_APWM	EC_APWM_MODE
ECCTL2	APWMPOL	EC_ACTV_HI
ECCTL2	SYNCI_EN	EC_DISABLE
ECCTL2	SYNCO_SEL	EC_SYNCO_DIS
ECCTL2	TSCTRSTOP	EC_RUN

Example 20-13. Code Snippet for APWM Mode

```
// Code snippet for APWM mode Example 1

// Run Time (Instant 1, e.g. ISR call)
//======================
   ECAPxRegs.CAP2 = 0x300;      // Set Duty cycle i.e. compare value

// Run Time (Instant 2, e.g. another ISR call)
//======================
   ECAPxRegs.CAP2 = 0x500;      // Set Duty cycle i.e. compare value
```

20.3.3.5.2 Multichannel PWM Generation with Synchronization Example

Figure 20-115 takes advantage of the synchronization feature between eCAP modules. Here 4 independent PWM channels are required with different frequencies, but at integer multiples of each other to avoid "beat" frequencies. Hence one eCAP module is configured as the Master and the remaining 3 are Slaves all receiving their synch pulse (CTR = PRD) from the master. Note the Master is chosen to have the lower frequency (F1 = 1/20,000) requirement. Here Slave2 Freq = 2 × F1, Slave3 Freq = 4 × F1 and Slave4 Freq = 5 × F1. Note here values are in decimal notation. Also, only the APWM1 output waveform is shown.

Figure 20-115. Multichannel PWM Example Using 4 eCAP Modules

Example 20-14. Code Snippet for Multichannel PWM Generation with Synchronization

```
// Code snippet for APWM mode Example 2

// Run Time (Note: Example execution of one run-time instant)
//=========================================================
   ECAP1Regs.CAP2 = 7000;    // Set Duty cycle i.e., compare value = 7000
   ECAP2Regs.CAP2 = 2000;    // Set Duty cycle i.e., compare value = 2000
   ECAP3Regs.CAP2 = 550;     // Set Duty cycle i.e., compare value = 550
   ECAP4Regs.CAP2 = 6500;    // Set Duty cycle i.e., compare value = 6500
```

20.3.3.5.3 Multichannel PWM Generation with Phase Control Example

In Figure 20-116, the Phase control feature of the APWM mode is used to control a 3 phase Interleaved DC/DC converter topology. This topology requires each phase to be off-set by 120° from each other. Hence if “Leg” 1 (controlled by APWM1) is the reference Leg (or phase), that is, 0°, then Leg 2 need 120° off-set and Leg 3 needs 240° off-set. The waveforms in Figure 20-116 show the timing relationship between each of the phases (Legs). Note eCAP1 module is the Master and issues a sync out pulse to the slaves (modules 2, 3) whenever TSCTR = Period value.

Figure 20-116. Multiphase (channel) Interleaved PWM Example Using 3 eCAP Modules

Example 20-15. Code Snippet for Multichannel PWM Generation with Phase Control

```
// Code snippet for APWM mode Example 3

// Run Time (Note: Example execution of one run-time instant)
//=========================================================
// All phases are set to the same duty cycle
  ECAP1Regs.CAP2 = 700;     // Set Duty cycle i.e. compare value = 700
  ECAP2Regs.CAP2 = 700;     // Set Duty cycle i.e. compare value = 700
  ECAP3Regs.CAP2 = 700;     // Set Duty cycle i.e. compare value = 700
```

20.3.4 Registers

All 32-bit registers are aligned on even address boundaries and are organized in little-endian mode. The 16 least-significant bits of a 32-bit register are located on lowest address (even address).

NOTE: In APWM mode, writing to CAP1/CAP2 active registers also writes the same value to the corresponding shadow registers CAP3/CAP4. This emulates immediate mode. Writing to the shadow registers CAP3/CAP4 invokes the shadow mode.

20.3.5 PWMSS_ECAP Registers

Table 20-101 lists the memory-mapped registers for the PWMSS_ECAP. All register offset addresses not listed in Table 20-101 should be considered as reserved locations and the register contents should not be modified.

Table 20-101. PWMSS_ECAP Registers

Offset	Acronym	Register Name	Section
0h	TSCTR	Time-Stamp Counter Register	Section 20.3.5.1
4h	CTRPHS	Counter Phase Offset Value Register	Section 20.3.5.2
8h	CAP1	Capture 1 Register	Section 20.3.5.3

</table>

Table 20-109. ECCTL2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-11	RESERVED	R	0h	
10	APWMPOL	R/W	0h	APWM output polarity select. This is applicable only in APWM operating mode 0h (R/W) = Output is active high (Compare value defines high time) 1h (R/W) = Output is active low (Compare value defines low time)
9	CAP_APWM	R/W	0h	CAP/APWM operating mode select 0h (R/W) = ECAP module operates in capture mode. This mode forces the following configuration. (a) Inhibits TSCTR resets via PRDEQ event. (b) Inhibits shadow loads on CAP1 and 2 registers. (c) Permits user to enable CAP1-4 register load. (d) ECAPn/APWMn pin operates as a capture input. 1h (R/W) = ECAP module operates in APWM mode. This mode forces the following configuration. (a) Resets TSCTR on PRDEQ event (period boundary). (b) Permits shadow loading on CAP1 and 2 registers. (c) Disables loading of time-stamps into CAP1-4 registers. (d) ECAPn/APWMn pin operates as a APWM output.
8	SWSYNC	R/W	0h	Software-forced Counter (TSCTR) Synchronizing. This provides a convenient software method to synchronize some or all ECAP time bases. In APWM mode, the synchronizing can also be done via the PRDEQ event. Note: Selecting PRDEQ is meaningful only in APWM mode. However, you can choose it in CAP mode if you find doing so useful. 0h (R/W) = Writing a zero has no effect. Reading always returns a zero 1h (R/W) = Writing a one forces a TSCTR shadow load of current ECAP module and any ECAP modules down-stream providing the SYNCO_SEL bits are 0,0. After writing a 1, this bit returns to a zero.
7-6	SYNCO_SEL	R/W	0h	Sync-Out Select 0h (R/W) = Select sync-in event to be the sync-out signal (pass through) 1h (R/W) = Select PRDEQ event to be the sync-out signal 2h (R/W) = Disable sync out signal 3h (R/W) = Disable sync out signal
5	SYNCI_EN	R/W	0h	Counter (TSCTR) Sync-In select mode 0h (R/W) = Disable sync-in option 1h (R/W) = Enable counter (TSCTR) to be loaded from CTRPHS register upon either a SYNCI signal or a S/W force event.
4	TSCTRSTOP	R/W	0h	Time Stamp (TSCTR) Counter Stop (freeze) Control 0h (R/W) = TSCTR stopped 1h (R/W) = TSCTR free-running

Table 20-109. ECCTL2 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	REARM	R/W	0h	One-Shot Re-Arming Control, that is, wait for stop trigger. Note: The re-arm function is valid in one shot or continuous mode. 0h (R/W) = Has no effect (reading always returns a 0) 1h (R/W) = Arms the one-shot sequence as follows: 1) Resets the Mod4 counter to zero. 2) Unfreezes the Mod4 counter. 3) Enables capture register loads.
2-1	STOP_WRAP	R/W	3h	Stop value for one-shot mode. This is the number (between 1 and 4) of captures allowed to occur before the CAP (1 through 4) registers are frozen, that is, capture sequence is stopped. Wrap value for continuous mode. This is the number (between 1 and 4) of the capture register in which the circular buffer wraps around and starts again. Notes: STOP_WRAP is compared to Mod4 counter and, when equal, the following two actions occur. (1) Mod4 counter is stopped (frozen), and (2) Capture register loads are inhibited. In one-shot mode, further interrupt events are blocked until re-armed. 0h (R/W) = Stop after Capture Event 1 in one-shot mode. Wrap after Capture Event 1 in continuous mode. 1h (R/W) = Stop after Capture Event 2 in one-shot mode. Wrap after Capture Event 2 in continuous mode. 2h (R/W) = Stop after Capture Event 3 in one-shot mode. Wrap after Capture Event 3 in continuous mode. 3h (R/W) = Stop after Capture Event 4 in one-shot mode. Wrap after Capture Event 4 in continuous mode.
0	CONT_ONESHT	R/W	0h	Continuous or one-shot mode control (applicable only in capture mode) 0h (R/W) = Operate in continuous mode 1h (R/W) = Operate in one-shot mode

20.3.5.9 ECEINT Register (Offset = 2Ch) [reset = 0h]

ECEINT is shown in Figure 20-125 and described in Table 20-110.

Return to Summary Table.

The interrupt enable bits (CEVTn) block any of the selected events from generating an interrupt. Events will still be latched into the flag bit (ECFLG register) and can be forced or cleared via the ECFRC and ECCLR registers. The proper procedure for configuring peripheral modes and interrupts is: 1. Disable global interrupts. 2. Stop eCAP counter. 3. Disable eCAP interrupts. 4. Configure peripheral registers. 5. Clear spurious eCAP interrupt flags. 6. Enable eCAP interrupts. 7. Start eCAP counter. 8. Enable global interrupts.

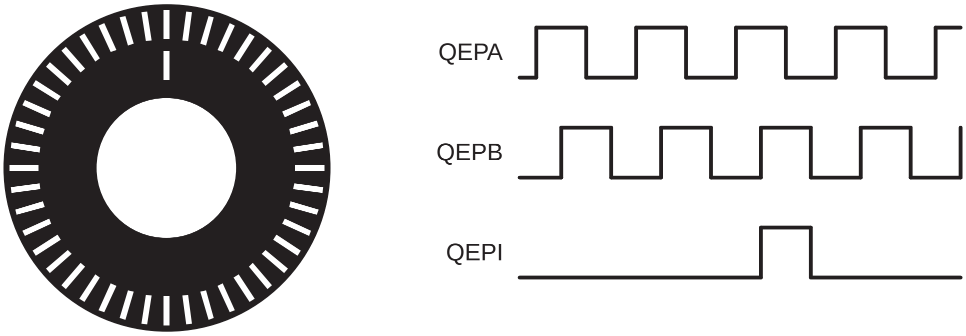
20.4 Enhanced Quadrature Encoder Pulse (eQEP) Module

20.4.1 Introduction

A single track of slots patterns the periphery of an incremental encoder disk, as shown in Figure 20-130. These slots create an alternating pattern of dark and light lines. The disk count is defined as the number of dark/light line pairs that occur per revolution (lines per revolution). As a rule, a second track is added to generate a signal that occurs once per revolution (index signal: QEPI), which can be used to indicate an absolute position. Encoder manufacturers identify the index pulse using different terms such as index, marker, home position, and zero reference.

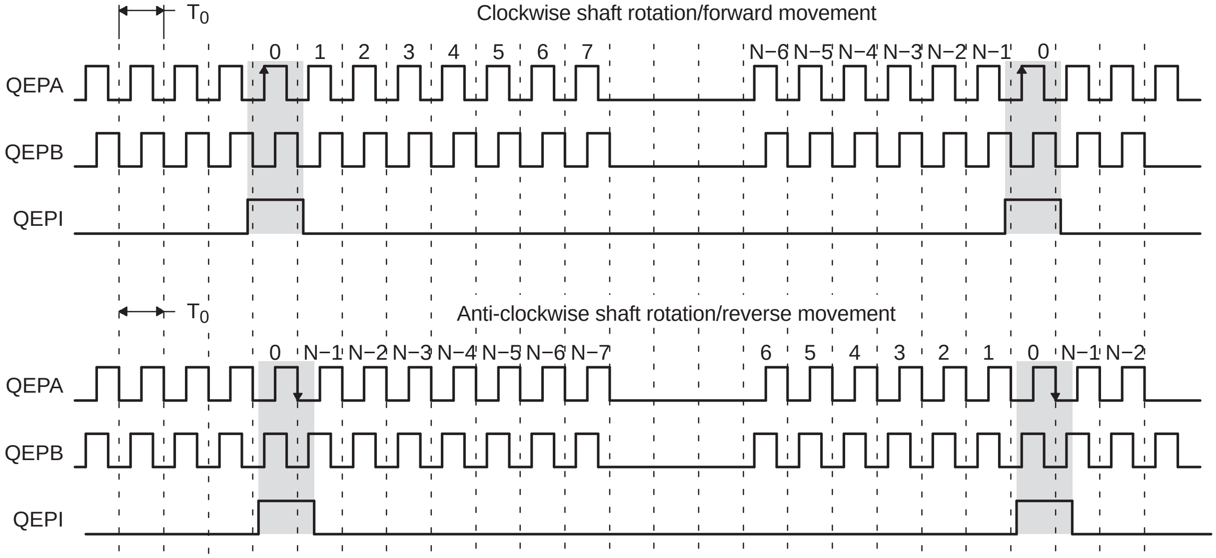
Figure 20-130. Optical Encoder Disk



To derive direction information, the lines on the disk are read out by two different photo-elements that "look" at the disk pattern with a mechanical shift of 1/4 the pitch of a line pair between them. This shift is realized with a reticle or mask that restricts the view of the photo-element to the desired part of the disk lines. As the disk rotates, the two photo-elements generate signals that are shifted 90 degrees out of phase from each other. These are commonly called the quadrature QEPA and QEPB signals. The clockwise direction for most encoders is defined as the QEPA channel going positive before the QEPB channel and vise versa as shown in Figure 20-131.

The encoder wheel typically makes one revolution for every revolution of the motor or the wheel may be at a geared rotation ratio with respect to the motor. Therefore, the frequency of the digital signal coming from the QEPA and QEPB outputs varies proportionally with the velocity of the motor. For example, a 2000-line encoder directly coupled to a motor running at 5000 revolutions per minute (rpm) results in a frequency of 166.6 KHz, so by measuring the frequency of either the QEPA or QEPB output, the processor can determine the velocity of the motor.

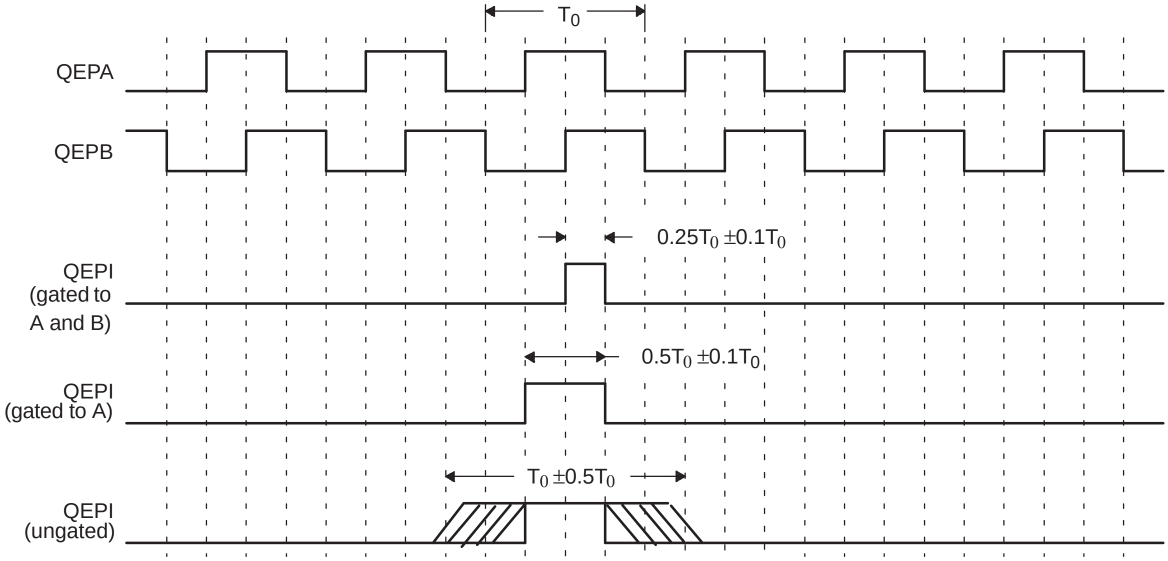
Figure 20-131. QEP Encoder Output Signal for Forward/Reverse Movement



Legend: N = lines per revolution

Quadrature encoders from different manufacturers come with two forms of index pulse (gated index pulse or ungated index pulse) as shown in Figure 20-132. A nonstandard form of index pulse is ungated. In the ungated configuration, the index edges are not necessarily coincident with A and B signals. The gated index pulse is aligned to any of the four quadrature edges and width of the index pulse and can be equal to a quarter, half, or full period of the quadrature signal.

Figure 20-132. Index Pulse Example



Some typical applications of shaft encoders include robotics and even computer input in the form of a mouse. Inside your mouse you can see where the mouse ball spins a pair of axles (a left/right, and an up/down axle). These axles are connected to optical shaft encoders that effectively tell the computer how fast and in what direction the mouse is moving.

General Issues: Estimating velocity from a digital position sensor is a cost-effective strategy in motor control. Two different first order approximations for velocity may be written as:

$$v(k) \approx \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \qquad (22)$$

$$v(k) \approx \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \qquad (23)$$

where

v(k): Velocity at time instant k

x(k): Position at time instant k

x(k-1): Position at time instant k - 1

T: Fixed unit time or inverse of velocity calculation rate

ΔX: Incremental position movement in unit time

t(k): Time instant "k"

t(k-1): Time instant "k - 1"

X: Fixed unit position

ΔT: Incremental time elapsed for unit position movement.

Equation 22 is the conventional approach to velocity estimation and it requires a time base to provide unit time event for velocity calculation. Unit time is basically the inverse of the velocity calculation rate.

The encoder count (position) is read once during each unit time event. The quantity [x(k) - x(k-1)] is formed by subtracting the previous reading from the current reading. Then the velocity estimate is computed by multiplying by the known constant 1/T (where T is the constant time between unit time events and is known in advance).

Estimation based on Equation 22 has an inherent accuracy limit directly related to the resolution of the position sensor and the unit time period T. For example, consider a 500-line per revolution quadrature encoder with a velocity calculation rate of 400 Hz. When used for position the quadrature encoder gives a four-fold increase in resolution, in this case, 2000 counts per revolution. The minimum rotation that can be detected is therefore 0.0005 revolutions, which gives a velocity resolution of 12 rpm when sampled at 400 Hz. While this resolution may be satisfactory at moderate or high speeds, for example, 1% error at 1200 rpm, it would clearly prove inadequate at low speeds. In fact, at speeds below 12 rpm, the speed estimate would erroneously be zero much of the time.

At low speed, Equation 23 provides a more accurate approach. It requires a position sensor that outputs a fixed interval pulse train, such as the aforementioned quadrature encoder. The width of each pulse is defined by motor speed for a given sensor resolution. Equation 23 can be used to calculate motor speed by measuring the elapsed time between successive quadrature pulse edges. However, this method suffers from the opposite limitation, as does Equation 22. A combination of relatively large motor speeds and high sensor resolution makes the time interval ΔT small, and thus more greatly influenced by the timer resolution. This can introduce considerable error into high-speed estimates.

For systems with a large speed range (that is, speed estimation is needed at both low and high speeds), one approach is to use Equation 23 at low speed and have the software switch over to Equation 22 when the motor speed rises above some specified threshold.

20.4.2 Functional Description

This section provides the eQEP inputs and functional description.

NOTE: Multiple identical eQEP modules can be contained in a system. The number of modules is device-dependent and is based on target application needs. In this document, the letter x within a signal or module name is used to indicate a generic eQEP instance on a device.

20.4.2.1 EQEP Inputs

The eQEP inputs include two pins for quadrature-clock mode or direction-count mode, an index (or 0 marker), and a strobe input.

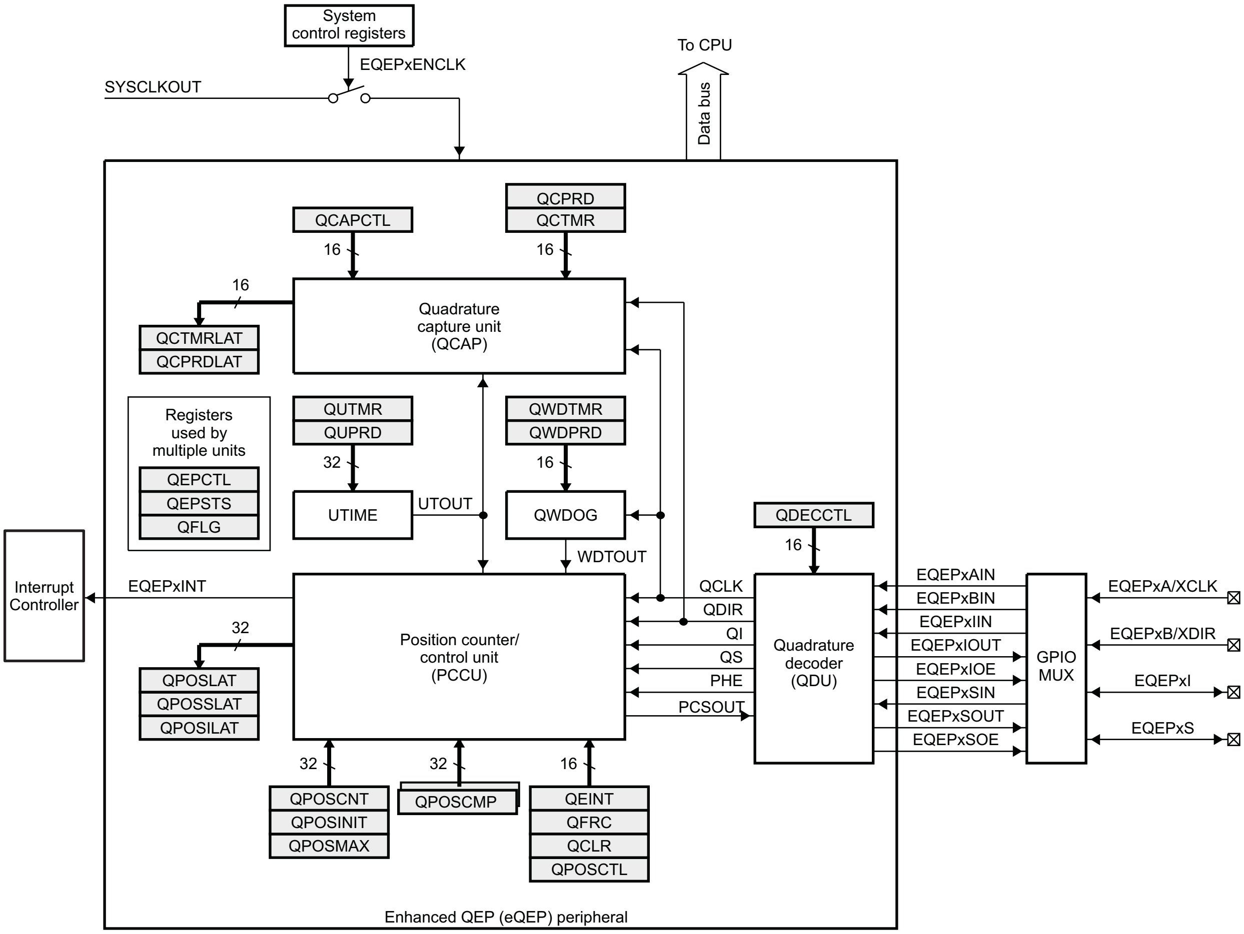
- QEPA/XCLK and QEPB/XDIR: These two pins can be used in quadrature-clock mode or direction-count mode.
  - Quadrature-clock Mode: The eQEP encoders provide two square wave signals (A and B) 90 electrical degrees out of phase whose phase relationship is used to determine the direction of rotation of the input shaft and number of eQEP pulses from the index position to derive the relative position information. For forward or clockwise rotation, QEPA signal leads QEPB signal and vice versa. The quadrature decoder uses these two inputs to generate quadrature-clock and direction signals.
  - Direction-count Mode: In direction-count mode, direction and clock signals are provided directly from the external source. Some position encoders have this type of output instead of quadrature output. The QEPA pin provides the clock input and the QEPB pin provides the direction input.
- QEPI: Index or Zero Marker: The eQEP encoder uses an index signal to assign an absolute start position from which position information is incrementally encoded using quadrature pulses. This pin is connected to the index output of the eQEP encoder to optionally reset the position counter for each revolution. This signal can be used to initialize or latch the position counter on the occurrence of a desired event on the index pin.
- QEPS: Strobe Input: This general-purpose strobe signal can initialize or latch the position counter on the occurrence of a desired event on the strobe pin. This signal is typically connected to a sensor or limit switch to notify that the motor has reached a defined position.

20.4.2.2 Functional Description

The eQEP peripheral contains the following major functional units (as shown in Figure 20-133):

- Programmable input qualification for each pin (part of the GPIO MUX)
- Quadrature decoder unit (QDU)
- Position counter and control unit for position measurement (PCCU)
- Quadrature edge-capture unit for low-speed measurement (QCAP)
- Unit time base for speed/frequency measurement (UTIME)
- Watchdog timer for detecting stalls (QWDOG)

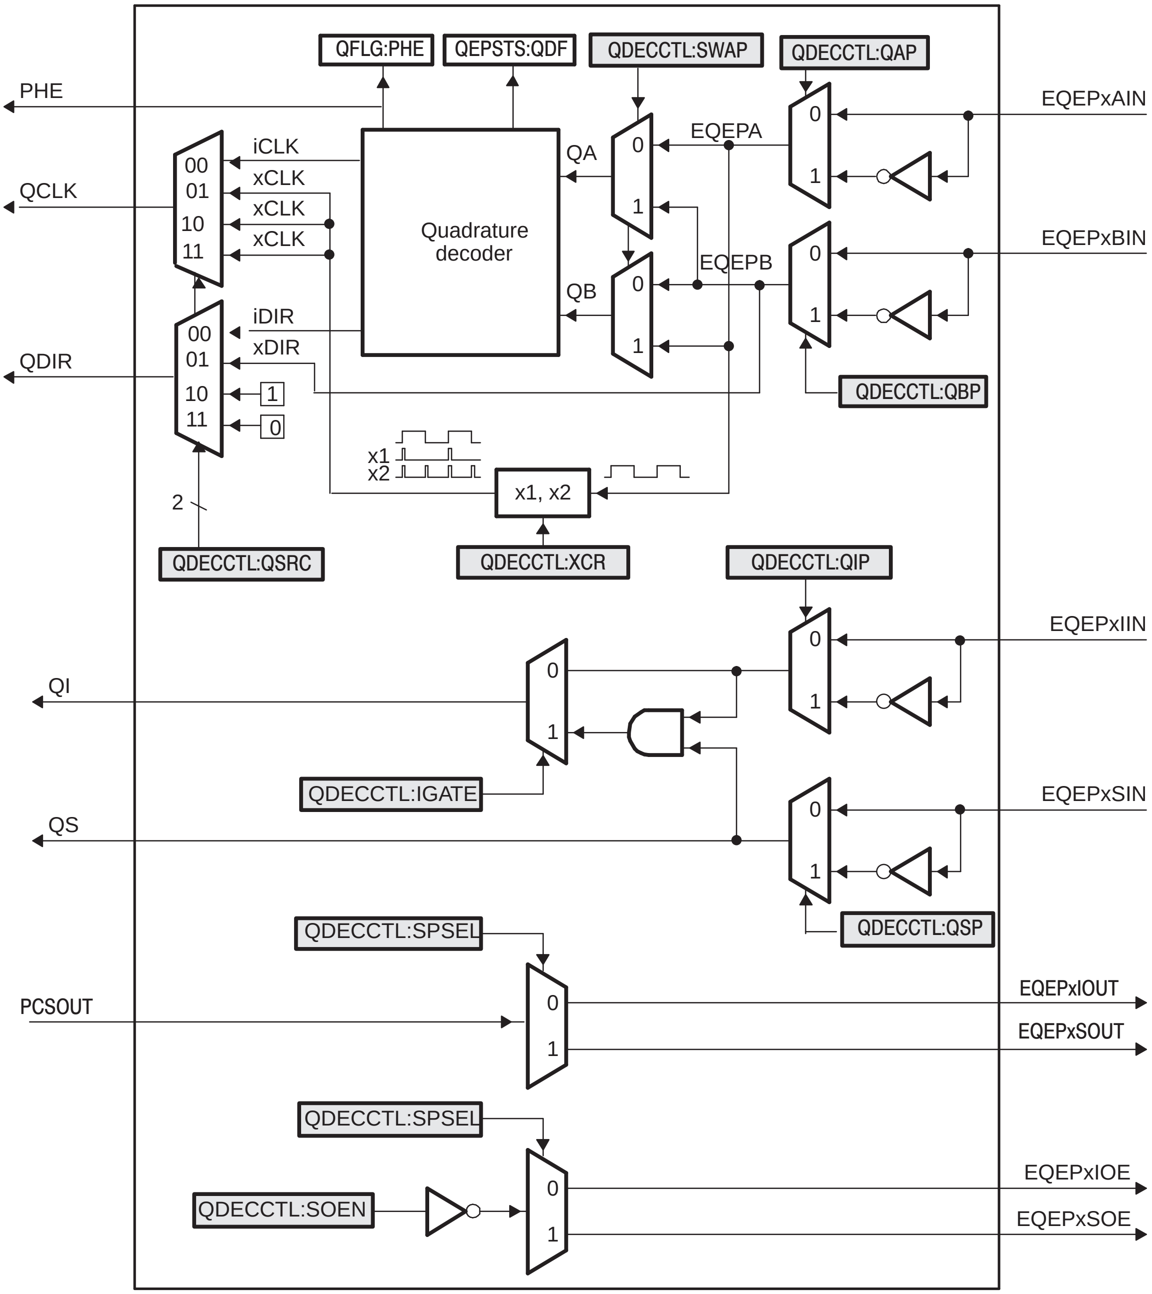
Figure 20-133. Functional Block Diagram of the eQEP Peripheral



20.4.2.3 Quadrature Decoder Unit (QDU)

Figure 20-134 shows a functional block diagram of the QDU.

Figure 20-134. Functional Block Diagram of Decoder Unit



20.4.2.3.1 Position Counter Input Modes

Clock and direction input to position counter is selected using the QSRC bit in the eQEP decoder control register (QDECCTL), based on interface input requirement as follows:

- Quadrature-count mode
- Direction-count mode
- UP-count mode
- DOWN-count mode

20.4.2.3.1.1 Quadrature Count Mode

The quadrature decoder generates the direction and clock to the position counter in quadrature count mode.

Direction Decoding— The direction decoding logic of the eQEP circuit determines which one of the sequences (QEPA, QEPB) is the leading sequence and accordingly updates the direction information in the QDF bit in the eQEP status register (QEPSTS). Table 20-115 and Figure 20-135 show the direction decoding logic in truth table and state machine form. Both edges of the QEPA and QEPB signals are sensed to generate count pulses for the position counter. Therefore, the frequency of the clock generated by the eQEP logic is four times that of each input sequence. Figure 20-136 shows the direction decoding and clock generation from the eQEP input signals.

Phase Error Flag— In normal operating conditions, quadrature inputs QEPA and QEPB will be 90 degrees out of phase. The phase error flag (PHE) is set in the QFLG register when edge transition is detected simultaneously on the QEPA and QEPB signals to optionally generate interrupts. State transitions marked by dashed lines in Figure 20-135 are invalid transitions that generate a phase error.

Count Multiplication— The eQEP position counter provides 4x times the resolution of an input clock by generating a quadrature-clock (QCLK) on the rising/falling edges of both eQEP input clocks (QEPA and QEPB) as shown in Figure 20-136.

Reverse Count— In normal quadrature count operation, QEPA input is fed to the QA input of the quadrature decoder and the QEPB input is fed to the QB input of the quadrature decoder. Reverse counting is enabled by setting the SWAP bit in the eQEP decoder control register (QDECCTL). This will swap the input to the quadrature decoder thereby reversing the counting direction.

Table 20-115. Quadrature Decoder Truth Table

	QB↑	TOGGLE	Increment or Decrement

Figure 20-135. Quadrature Decoder State Machine

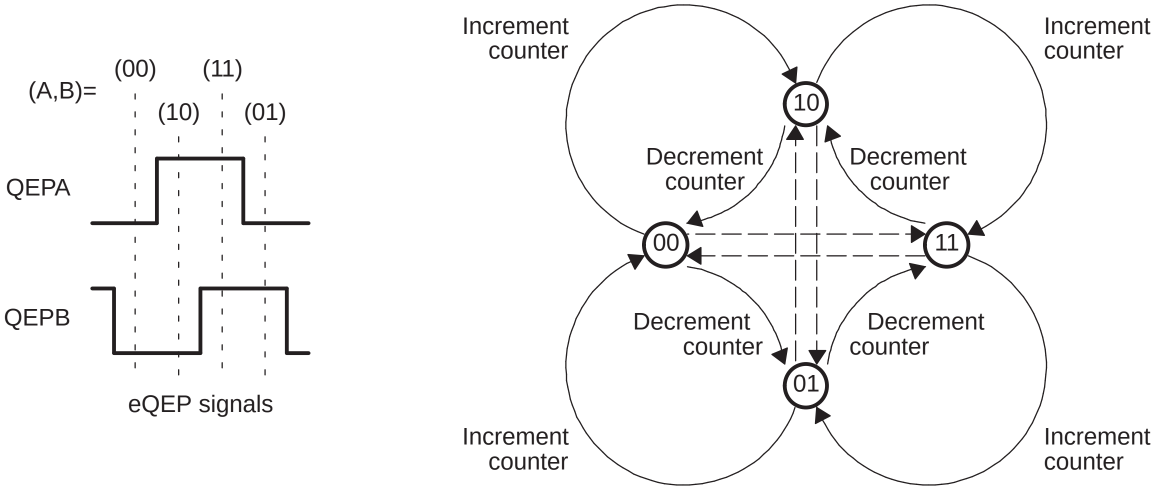

Figure 20-136. Quadrature-clock and Direction Decoding

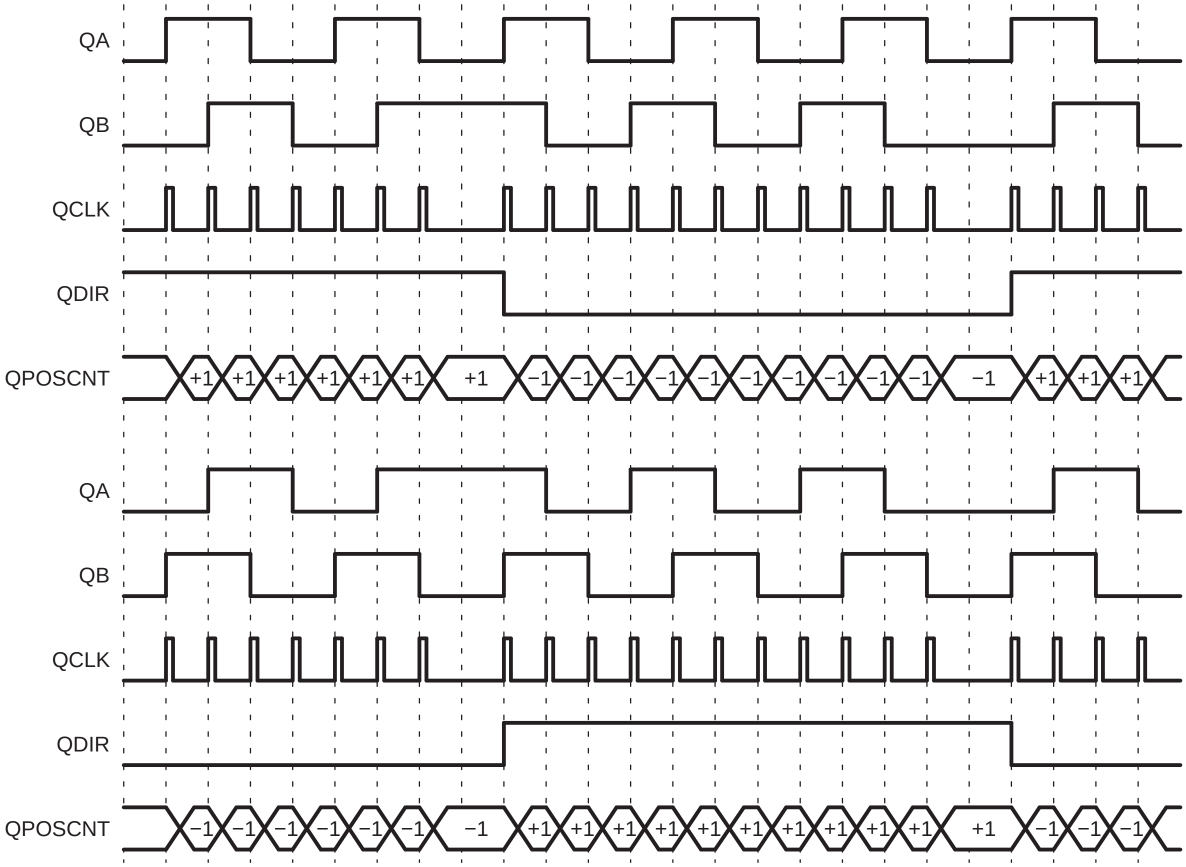


20.4.2.3.1.2 Direction-count Mode

Some position encoders provide direction and clock outputs, instead of quadrature outputs. In such cases, direction-count mode can be used. QEPA input will provide the clock for position counter and the QEPB input will have the direction information. The position counter is incremented on every rising edge of a QEPA input when the direction input is high and decremented when the direction input is low.

20.4.2.3.1.3 Up-Count Mode

The counter direction signal is hard-wired for up count and the position counter is used to measure the frequency of the QEPA input. Setting of the XCR bit in the eQEP decoder control register (QDECCTL) enables clock generation to the position counter on both edges of the QEPA input, thereby increasing the measurement resolution by 2× factor.

20.4.2.3.1.4 Down-Count Mode

The counter direction signal is hardwired for a down count and the position counter is used to measure the frequency of the QEPA input. Setting of the XCR bit in the eQEP decoder control register (QDECCTL) enables clock generation to the position counter on both edges of a QEPA input, thereby increasing the measurement resolution by 2× factor.

20.4.2.3.2 eQEP Input Polarity Selection

Each eQEP input can be inverted using the in the eQEP decoder control register (QDECCTL[8:5]) control bits. As an example, setting of the QIP bit in QDECCTL inverts the index input.

20.4.2.3.3 Position-Compare Sync Output

The eQEP peripheral includes a position-compare unit that is used to generate the position-compare sync signal on compare match between the position counter register (QPOSCNT) and the position-compare register (QPOSCMP). This sync signal can be output using an index pin or strobe pin of the EQEP peripheral.

Setting the SOEN bit in the eQEP decoder control register (QDECCTL) enables the position-compare sync output and the SPSEL bit in QDECCTL selects either an eQEP index pin or an eQEP strobe pin.

20.4.2.4 Position Counter and Control Unit (PCCU)

The position counter and control unit provides two configuration registers (QEPCTL and QPOSCTL) for setting up position counter operational modes, position counter initialization/latch modes and position-compare logic for sync signal generation.

20.4.2.4.1 Position Counter Operating Modes

Position counter data may be captured in different manners. In some systems, the position counter is accumulated continuously for multiple revolutions and the position counter value provides the position information with respect to the known reference. An example of this is the quadrature encoder mounted on the motor controlling the print head in the printer. Here the position counter is reset by moving the print head to the home position and then position counter provides absolute position information with respect to home position.

In other systems, the position counter is reset on every revolution using index pulse and position counter provides rotor angle with respect to index pulse position.

Position counter can be configured to operate in following four modes

- Position Counter Reset on Index Event
- Position Counter Reset on Maximum Position
- Position Counter Reset on the first Index Event
- Position Counter Reset on Unit Time Out Event (Frequency Measurement)

In all the above operating modes, position counter is reset to 0 on overflow and to QPOSMAX register value on underflow. Overflow occurs when the position counter counts up after QPOSMAX value. Underflow occurs when position counter counts down after "0". Interrupt flag is set to indicate overflow/underflow in QFLG register.

20.4.2.4.1.1 Position Counter Reset on Index Event (QEPCTL[PCRM] = 00)

If the index event occurs during the forward movement, then position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock.

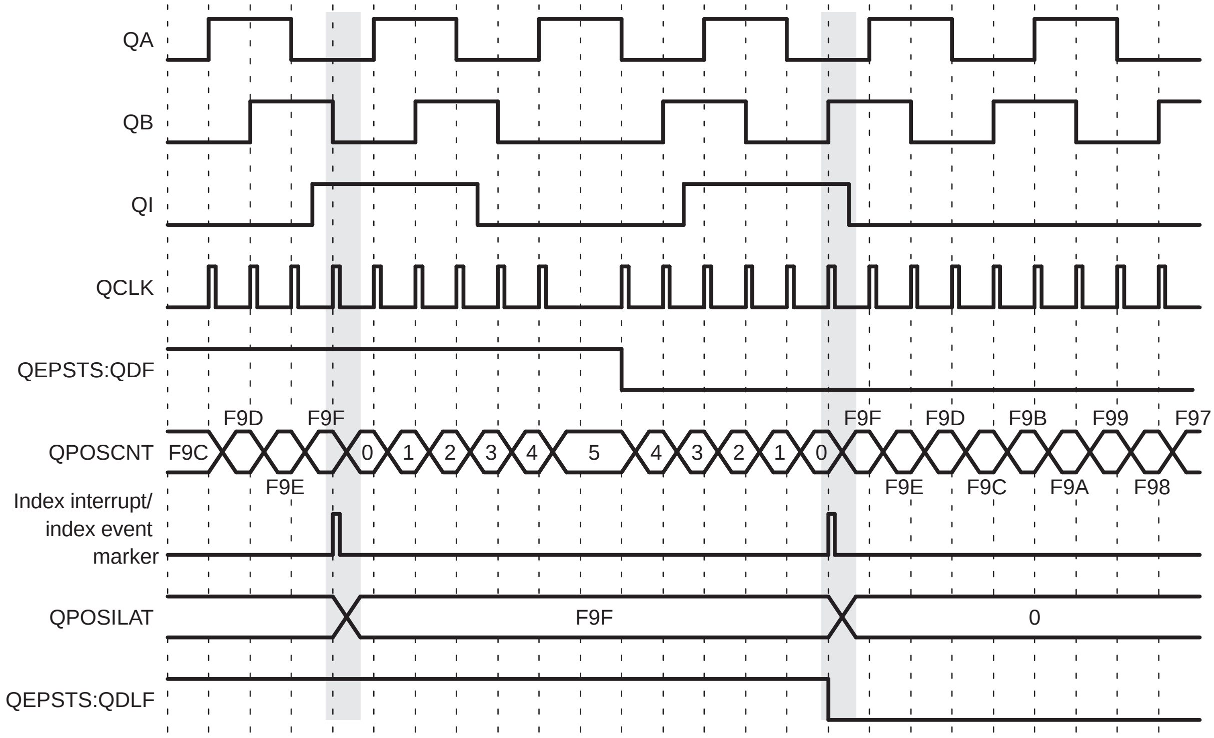
First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers, it also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for index event reset operation.

For example, if the first reset operation occurs on the falling edge of QEPB during the forward direction, then all the subsequent reset must be aligned with the falling edge of QEPB for the forward rotation and on the rising edge of QEPB for the reverse rotation as shown in Figure 20-137.

The position-counter value is latched to the QPOSILAT register and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker. The position-counter error flag (QEPSTS[PCEF]) and error interrupt flag (QFLG[PCE]) are set if the latched value is not equal to 0 or QPOSMAX. The position-counter error flag (QEPSTS[PCEF]) is updated on every index event marker and an interrupt flag (QFLG[PCE]) will be set on error that can be cleared only through software.

The index event latch configuration QEPCTL[IEL] bits are ignored in this mode and position counter error flag/interrupt flag are generated only in index event reset mode.

Figure 20-137. Position Counter Reset by Index Pulse for 1000 Line Encoder (QPOSMAX = 3999 or F9Fh)

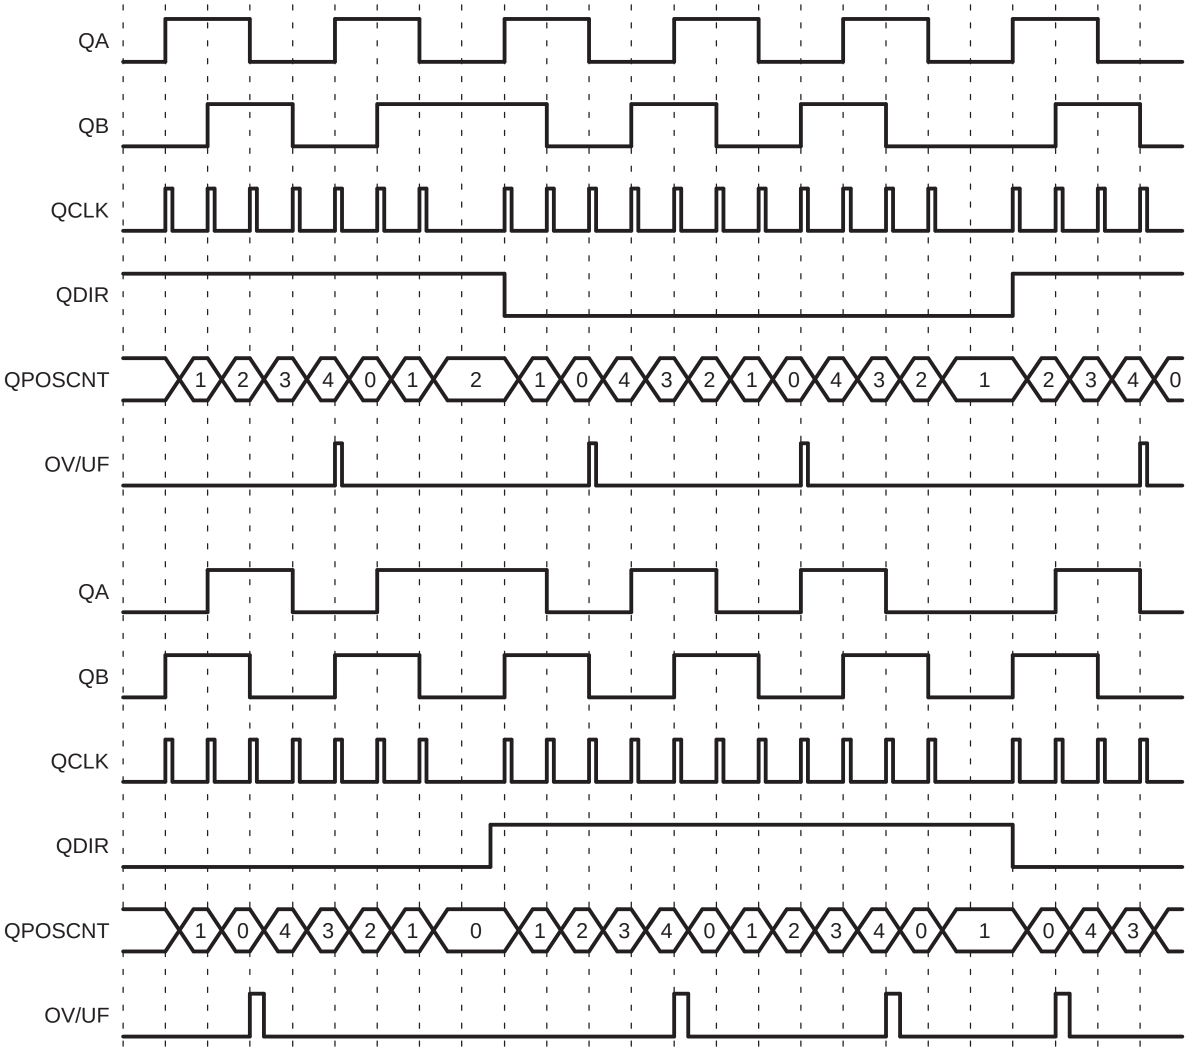


20.4.2.4.1.2 Position Counter Reset on Maximum Position (QEPCTL[PCRM]=01)

If the position counter is equal to QPOSMAX, then the position counter is reset to 0 on the next eQEP clock for forward movement and position counter overflow flag is set. If the position counter is equal to ZERO, then the position counter is reset to QPOSMAX on the next QEP clock for reverse movement and position counter underflow flag is set. Figure 20-138 shows the position counter reset operation in this mode.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers; it also remembers the quadrature edge on the first index marker so that the same relative quadrature transition is used for the software index marker (QEPCTL[IEL]=11).

Figure 20-138. Position Counter Underflow/Overflow (QPOSMAX = 4)



20.4.2.4.1.3 Position Counter Reset on the First Index Event (QEPCTL[PCRM] = 10)

If the index event occurs during forward movement, then the position counter is reset to 0 on the next eQEP clock. If the index event occurs during the reverse movement, then the position counter is reset to the value in the QPOSMAX register on the next eQEP clock. Note that this is done only on the first occurrence and subsequently the position counter value is not reset on an index event; rather, it is reset based on maximum position as described in Section 20.4.2.4.1.2.

First index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for software index marker (QEPCTL[IEL]=11).

20.4.2.4.1.4 Position Counter Reset on Unit Time out Event (QEPCTL[PCRM] = 11)

In this mode, the QPOSCNT value is latched to the QPOSLAT register and then the QPOSCNT is reset (to 0 or QPOSMAX, depending on the direction mode selected by QDECCTL[QSRC] bits on a unit time event). This is useful for frequency measurement.

20.4.2.4.2 Position Counter Latch

The eQEP index and strobe input can be configured to latch the position counter (QPOSCNT) into QPOSILAT and QPOSSLAT, respectively, on occurrence of a definite event on these pins.

20.4.2.4.2.1 Index Event Latch

In some applications, it may not be desirable to reset the position counter on every index event and instead it may be required to operate the position counter in full 32-bit mode (QEPCTL[PCRM] = 01 and QEPCTL[PCRM] = 10 modes).

In such cases, the eQEP position counter can be configured to latch on the following events and direction information is recorded in the QEPSTS[QDLF] bit on every index event marker.

- Latch on Rising edge (QEPCTL[IEL] = 01)
- Latch on Falling edge (QEPCTL[IEL] = 10)
- Latch on Index Event Marker (QEPCTL[IEL] = 11)

This is particularly useful as an error checking mechanism to check if the position counter accumulated the correct number of counts between index events. As an example, the 1000-line encoder must count 4000 times when moving in the same direction between the index events.

The index event latch interrupt flag (QFLG[IEL]) is set when the position counter is latched to the QPOSILAT register. The index event latch configuration bits (QEPCTZ[IEL]) are ignored when QEPCTL[PCRM] = 00.

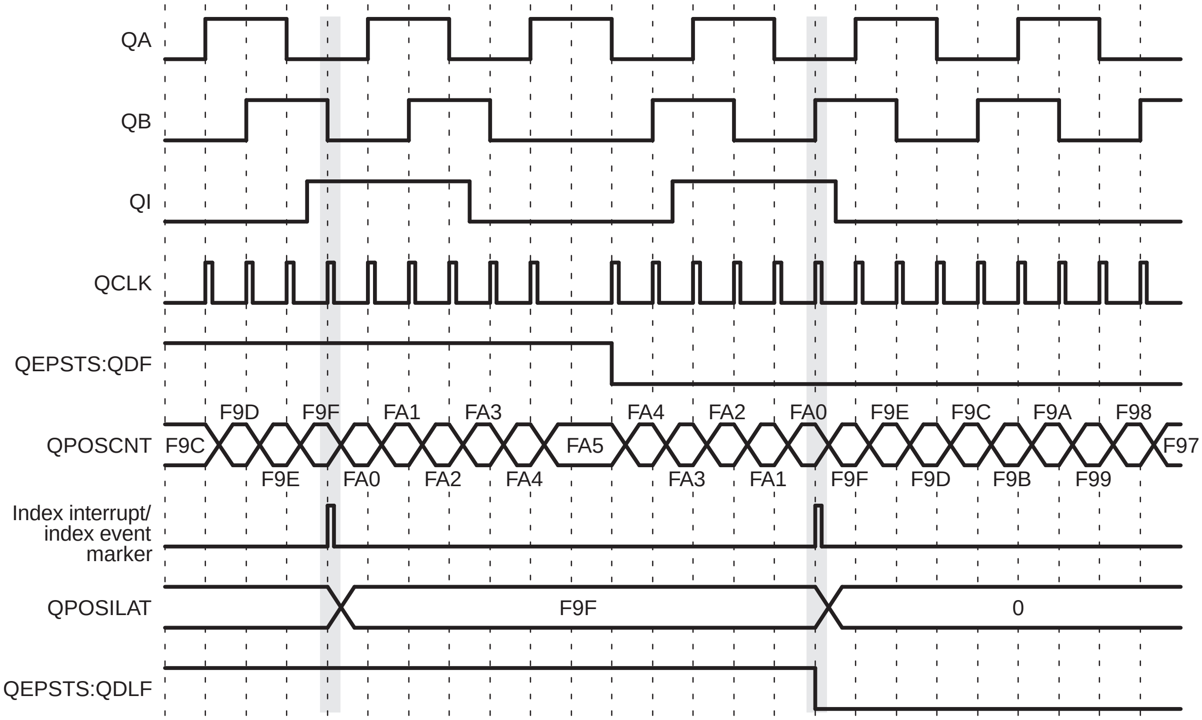
Latch on Rising Edge (QEPCTL[IEL] = 01)— The position counter value (QPOSCNT) is latched to the QPOSILAT register on every rising edge of an index input.

Latch on Falling Edge (QEPCTL[IEL] = 10)— The position counter value (QPOSCNT) is latched to the QPOSILAT register on every falling edge of index input.

Latch on Index Event Marker/Software Index Marker (QEPCTL[IEL] = 11)— The first index marker is defined as the quadrature edge following the first index edge. The eQEP peripheral records the occurrence of the first index marker (QEPSTS[FIMF]) and direction on the first index event marker (QEPSTS[FIDF]) in the QEPSTS registers. It also remembers the quadrature edge on the first index marker so that same relative quadrature transition is used for latching the position counter (QEPCTL[IEL] = 11).

Figure 20-139 shows the position counter latch using an index event marker.

Figure 20-139. Software Index Marker for 1000-line Encoder (QEPCTL[IEL] = 1)



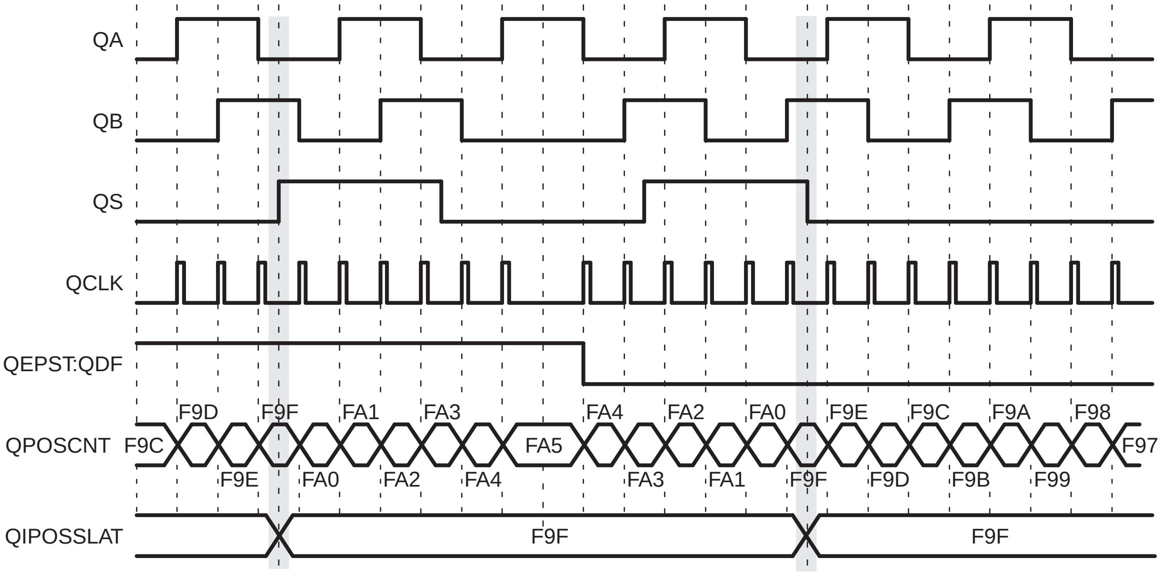
20.4.2.4.2.2 Strobe Event Latch

The position-counter value is latched to the QPOSSLAT register on the rising edge of the strobe input by clearing the QEPCTL[SEL] bit.

If the QEPCTL[SEL] bit is set, then the position counter value is latched to the QPOSSLAT register on the rising edge of the strobe input for forward direction and on the falling edge of the strobe input for reverse direction as shown in Figure 20-140.

The strobe event latch interrupt flag (QFLG[SEL]) is set when the position counter is latched to the QPOSSLAT register.

Figure 20-140. Strobe Event Latch (QEPCTL[SEL] = 1)



20.4.2.4.3 Position Counter Initialization

The position counter can be initialized using following events:

- Index event
- Strobe event
- Software initialization

Index Event Initialization (IEI)— The QEPI index input can be used to trigger the initialization of the position counter at the rising or falling edge of the index input.

If the QEPCTL[IEI] bits are 10, then the position counter (QPOSCNT) is initialized with a value in the QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

The index event initialization interrupt flag (QFLG[IEI]) is set when the position counter is initialized with a value in the QPOSINIT register.

Strobe Event Initialization (SEI)— If the QEPCTL[SEI] bits are 10, then the position counter is initialized with a value in the QPOSINIT register on the rising edge of strobe input.

If the QEPCTL[SEL] bits are 11, then the position counter (QPOSCNT) is initialized with a value in the QPOSINIT register on the rising edge of strobe input for forward direction and on the falling edge of strobe input for reverse direction.

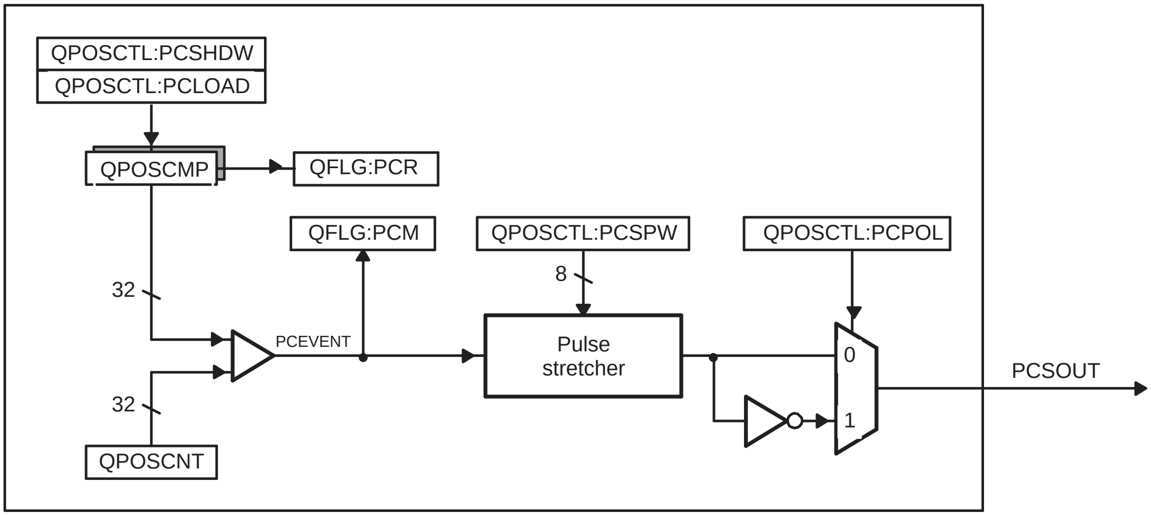
The strobe event initialization interrupt flag (QFLG[SEI]) is set when the position counter is initialized with a value in the QPOSINIT register.

Software Initialization (SWI)— The position counter can be initialized in software by writing a 1 to the QEPCTL[SWI] bit, which will automatically be cleared after initialization.

20.4.2.4.4 eQEP Position-compare Unit

The eQEP peripheral includes a position-compare unit that is used to generate a sync output and/or interrupt on a position-compare match. Figure 20-141 shows a diagram. The position-compare (QPOSCMP) register is shadowed and shadow mode can be enabled or disabled using the QPOSCTL[PSSHDW] bit. If the shadow mode is not enabled, the CPU writes directly to the active position compare register.

Figure 20-141. eQEP Position-compare Unit



In shadow mode, you can configure the position-compare unit (QPOSCTL[PCLOAD]) to load the shadow register value into the active register on the following events and to generate the position-compare ready (QFLG[PCR]) interrupt after loading.

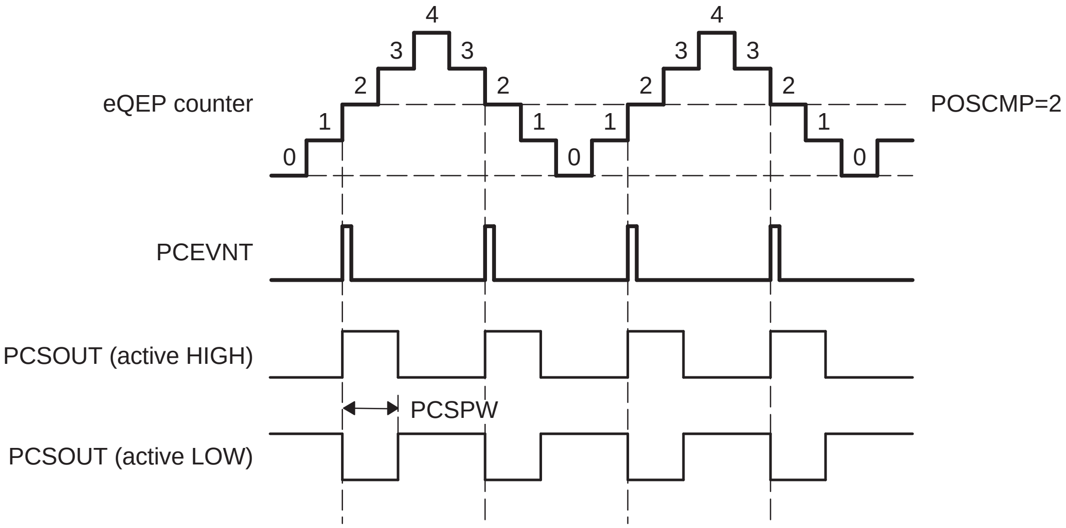
- Load on compare match
- Load on position-counter zero event

The position-compare match (QFLG[PCM]) is set when the position-counter value (QPOSCNT) matches with the active position-compare register (QPOSCMP) and the position-compare sync output of the programmable pulse width is generated on compare match to trigger an external device.

For example, if QPOSCMP = 2, the position-compare unit generates a position-compare event on 1 to 2 transitions of the eQEP position counter for forward counting direction and on 3 to 2 transitions of the eQEP position counter for reverse counting direction (see Figure 20-142).

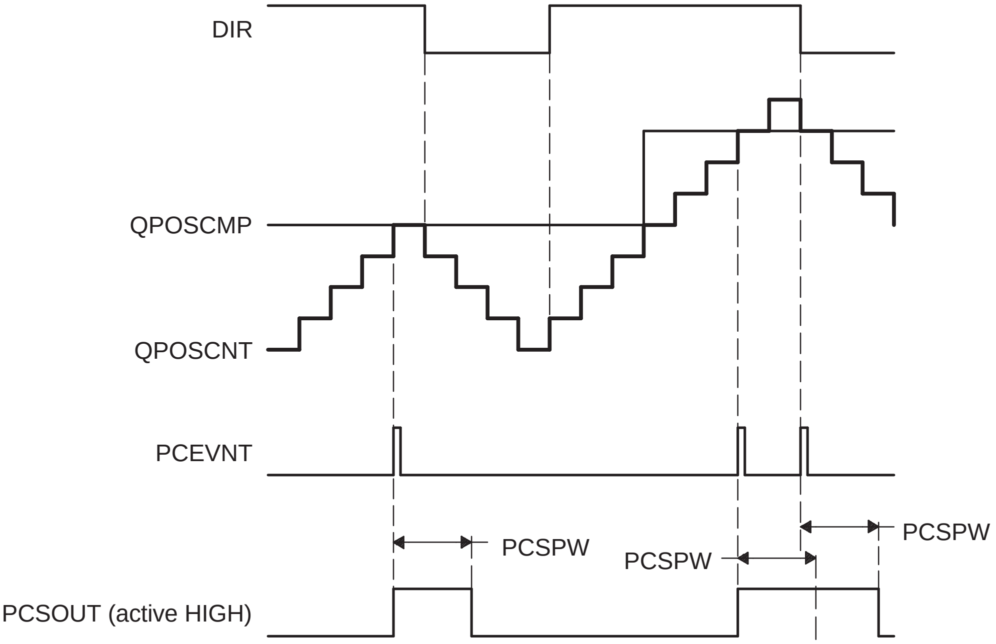
shows the layout of the eQEP Position-Compare Control Register (QPOSCTL) and describes the QPOSCTL bit fields.

Figure 20-142. eQEP Position-compare Event Generation Points



The pulse stretcher logic in the position-compare unit generates a programmable position-compare sync pulse output on the position-compare match. In the event of a new position-compare match while a previous position-compare pulse is still active, then the pulse stretcher generates a pulse of specified duration from the new position-compare event as shown in Figure 20-143.

Figure 20-143. eQEP Position-compare Sync Output Pulse Stretcher



20.4.2.5 eQEP Edge Capture Unit

The eQEP peripheral includes an integrated edge capture unit to measure the elapsed time between the unit position events as shown in Figure 20-144. This feature is typically used for low speed measurement using the following equation:

$$v(k) = \frac{X}{t(k) - t(k-1)} = \frac{X}{\Delta T} \tag{24}$$

where,

- X - Unit position is defined by integer multiple of quadrature edges (see Figure 20-145)
- ΔT - Elapsed time between unit position events
- v(k) - Velocity at time instant "k"

The eQEP capture timer (QCTMR) runs from prescaled SYSCLKOUT and the prescaler is programmed by the QCAPCTL[CCPS] bits. The capture timer (QCTMR) value is latched into the capture period register (QCPRD) on every unit position event and then the capture timer is reset, a flag is set in QEPSTS[UPEVNT] to indicate that new value is latched into the QCPRD register. Software can check this status flag before reading the period register for low speed measurement and clear the flag by writing 1.

Time measurement (ΔT) between unit position events will be correct if the following conditions are met:

- No more than 65,535 counts have occurred between unit position events.
- No direction change between unit position events.

The capture unit sets the eQEP overflow error flag (QEPSTS[COEF]) in the event of capture timer overflow between unit position events. If a direction change occurs between the unit position events, then an error flag is set in the status register (QEPSTS[CDEF]).

Capture Timer (QCTMR) and Capture period register (QCPRD) can be configured to latch on following events.

- CPU read of QPOSCNT register
- Unit time-out event

If the QEPCTL[QCLM] bit is cleared, then the capture timer and capture period values are latched into the QCTMRLAT and QCPRDLAT registers, respectively, when the CPU reads the position counter (QPOSCNT).

If the QEPCTL[QCLM] bit is set, then the position counter, capture timer, and capture period values are latched into the QPOSLAT, QCTMRLAT and QCPRDLAT registers, respectively, on unit time out.

Figure 20-146 shows the capture unit operation along with the position counter.

NOTE: The QCAPCTL register should not be modified dynamically (such as switching CAPCLK prescaling mode from QCLK/4 to QCLK/8). The capture unit must be disabled before changing the prescaler.

Figure 20-144. eQEP Edge Capture Unit

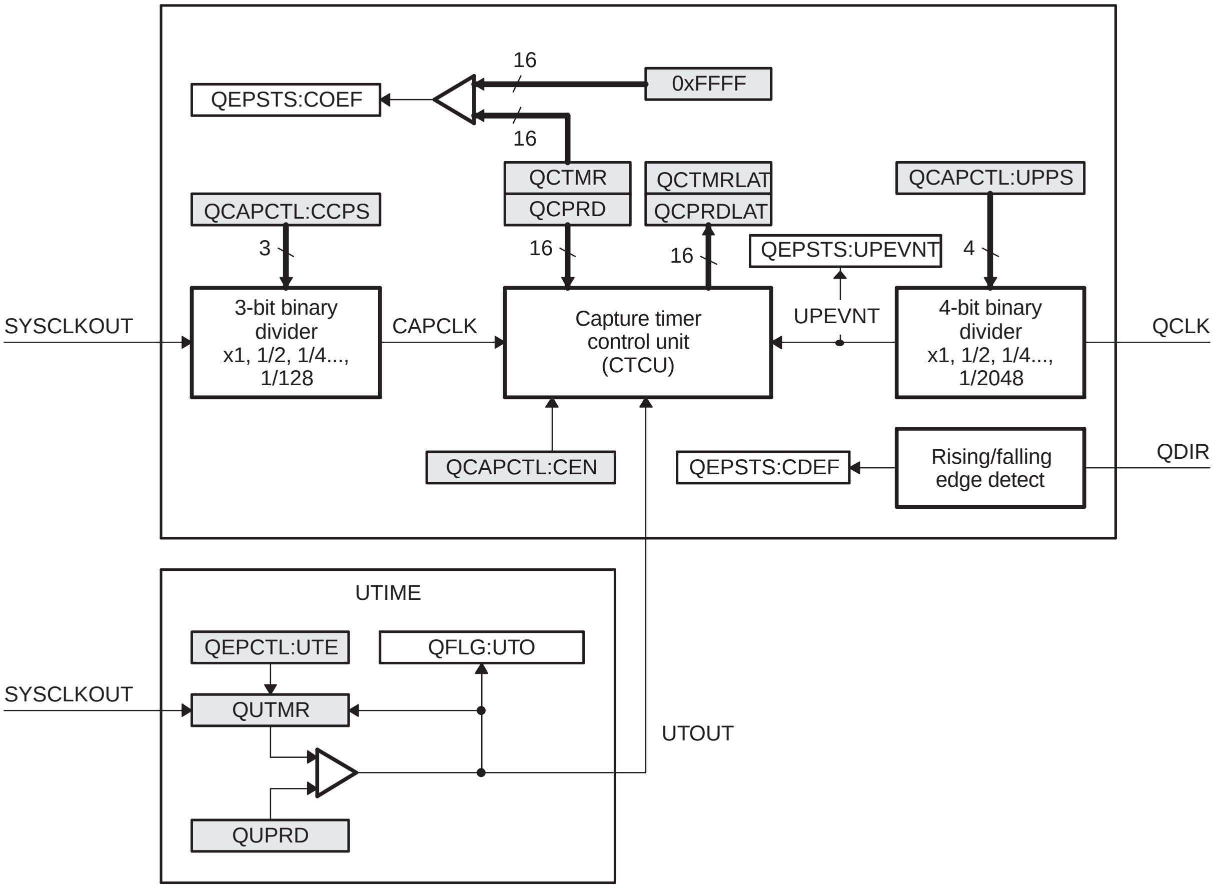


Figure 20-145. Unit Position Event for Low Speed Measurement (QCAPCTL[UPPS] = 0010)

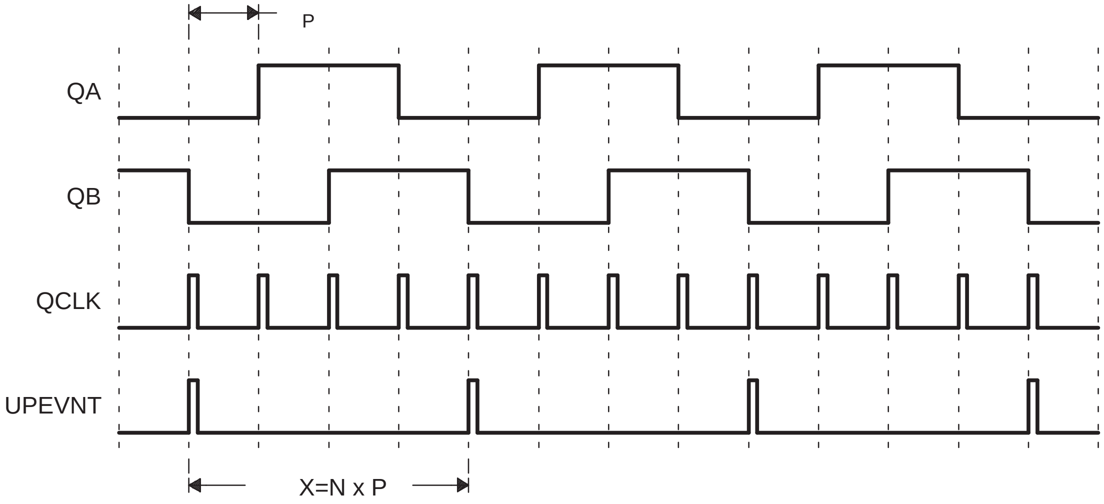
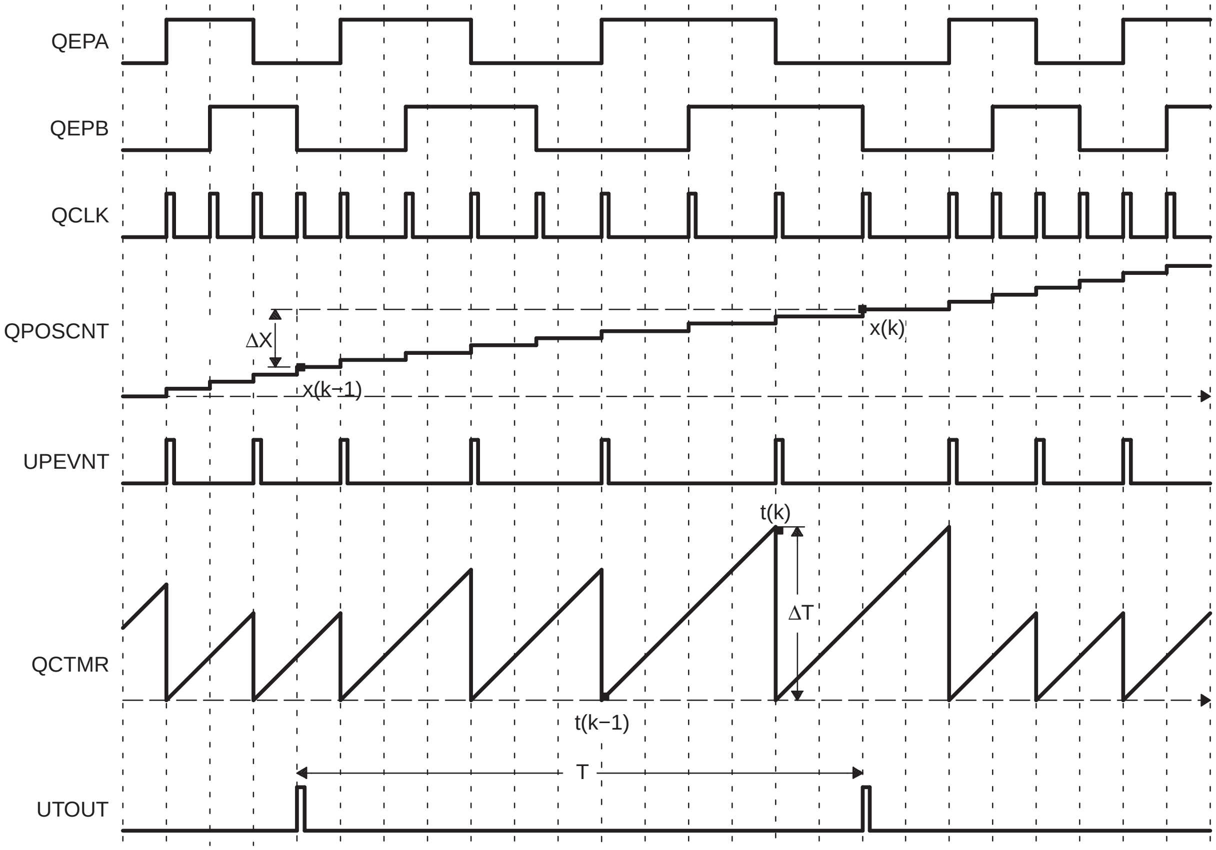


N - Number of quadrature periods selected using QCAPCTL[UPPS] bits

Figure 20-146. eQEP Edge Capture Unit - Timing Details



Velocity Calculation Equations:

$$v(k) = \frac{x(k) - x(k-1)}{T} = \frac{\Delta X}{T} \text{ o} \qquad (25)$$

where

v(k): Velocity at time instant k

x(k): Position at time instant k

x(k-1): Position at time instant k - 1

T: Fixed unit time or inverse of velocity calculation rate

ΔX: Incremental position movement in unit time

X: Fixed unit position

ΔT: Incremental time elapsed for unit position movement

t(k): Time instant "k"

t(k-1): Time instant "k - 1"

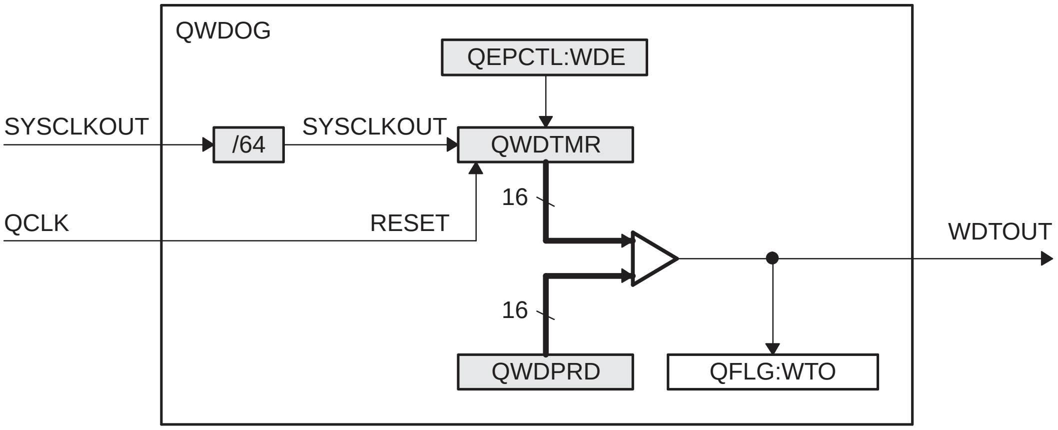
Unit time (T) and unit period (X) are configured using the QUPRD and QCAPCTL[UPPS] registers. Incremental position output and incremental time output is available in the QPOSLAT and QCPRDLAT registers.

Parameter	Relevant Register to Configure or Read the Information
T	Unit Period Register (QUPRD)
ΔX	Incremental Position = QPOSLAT(k) - QPOSLAT(K - 1)
X	Fixed unit position defined by sensor resolution and ZCAPCTL[UPPS] bits
ΔT	Capture Period Latch (QCPRDLAT)

20.4.2.6 eQEP Watchdog

The eQEP peripheral contains a 16-bit watchdog timer that monitors the quadrature-clock to indicate proper operation of the motion-control system. The eQEP watchdog timer is clocked from SYSCLKOUT/64 and the quadrate clock event (pulse) resets the watchdog timer. If no quadrature-clock event is detected until a period match (QWDPRD = QWDTMR), then the watchdog timer will time out and the watchdog interrupt flag will be set (QFLG[WTO]). The time-out value is programmable through the watchdog period register (QWDPRD).

Figure 20-147. eQEP Watchdog Timer

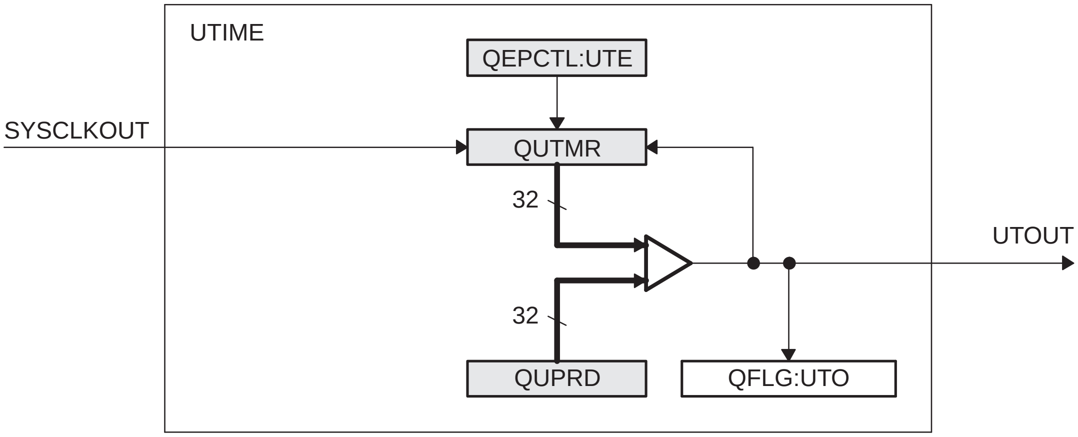


20.4.2.7 Unit Timer Base

The eQEP peripheral includes a 32-bit timer (QUTMR) that is clocked by SYSCLKOUT to generate periodic interrupts for velocity calculations. The unit time out interrupt is set (QFLG[UTO]) when the unit timer (QUTMR) matches the unit period register (QUPRD).

The eQEP peripheral can be configured to latch the position counter, capture timer, and capture period values on a unit time out event so that latched values are used for velocity calculation as described in Section Section 20.4.2.5.

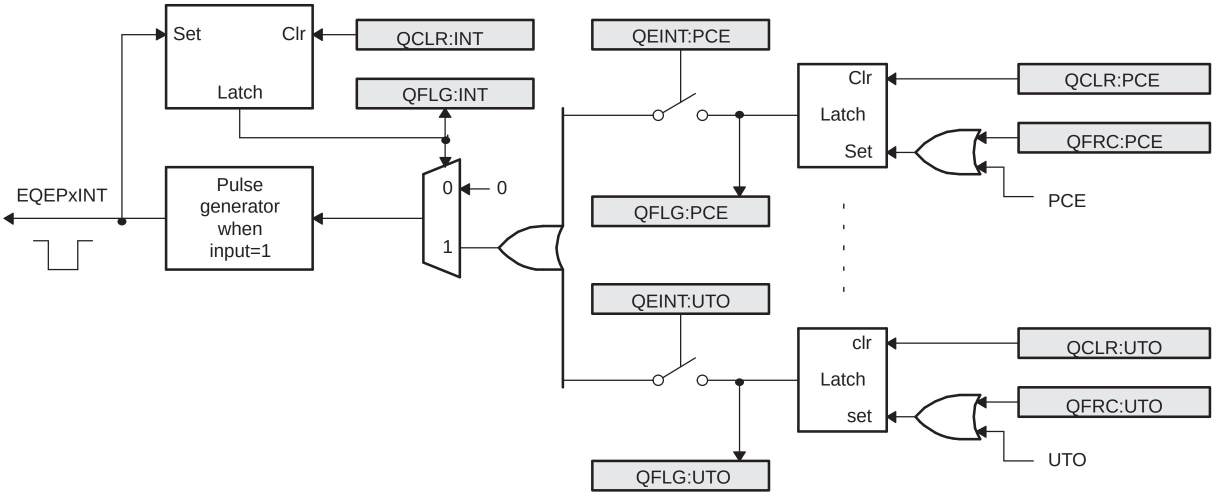
Figure 20-148. eQEP Unit Time Base



20.4.2.8 eQEP Interrupt Structure

Figure 20-149 shows how the interrupt mechanism works in the EQEP module.

Figure 20-149. EQEP Interrupt Generation



Eleven interrupt events (PCE, PHE, QDC, WTO, PCU, PCO, PCR, PCM, SEL, IEL, and UTO) can be generated. The interrupt control register (QEINT) is used to enable/disable individual interrupt event sources. The interrupt flag register (QFLG) indicates if any interrupt event has been latched and contains the global interrupt flag bit (INT). An interrupt pulse is generated only to the interrupt controller if any of the interrupt events is enabled, the flag bit is 1 and the INT flag bit is 0. The interrupt service routine will need to clear the global interrupt flag bit and the serviced event, via the interrupt clear register (QCLR), before any other interrupt pulses are generated. You can force an interrupt event by way of the interrupt force register (QFRC), which is useful for test purposes.

Note that the interrupts coming from the eQEP module are also used as DMA events. The interrupt registers should be used to enable and clear the current DMA event in order for the eQEP module to generate subsequent DMA events.

20.4.3 PWMSS_EQEP Registers

Table 20-116 lists the memory-mapped registers for the PWMSS_EQEP. All register offset addresses not listed in Table 20-116 should be considered as reserved locations and the register contents should not be modified.

Table 20-116. PWMSS_EQEP REGISTERS

Offset	Acronym	Register Name	Section
0h	QPOSCNT	eQEP Position Counter Register	Section 20.4.3.1

Table 20-129. QEPCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-14	FREE_SOFT	R/W	0h	Emulation Control Bits. In the values 0 through 3 listed below, x is different for the four following behaviors. QPOSCNT behavior, x refers to the Position counter. QWDTMR behavior, x refers to the Watchdog counter. QUTMR behavior, x refers to the Unit timer. QCTMR behavior, x refers to the Capture timer. 0h = x stops immediately. For QPOSCNT behavior, the stop is on emulation suspend. 1h = x continues to count until the rollover. 2h = x is unaffected by emulation suspend. 3h = x is unaffected by emulation suspend.
13-12	PCRM	R/W	0h	Position counter reset mode 0h = Position counter reset on an index event 1h = Position counter reset on the maximum position 2h = Position counter reset on the first index event 3h = Position counter reset on a unit time event
11-10	SEI	R/W	0h	Strobe event initialization of position counter 0h = Does nothing (action disabled) 1h = Does nothing (action disabled) 2h = Initializes the position counter on rising edge of the QEPS signal 3h = Clockwise Direction: Initializes the position counter on the rising edge of QEPS strobe. Counter Clockwise Direction: Initializes the position counter on the falling edge of QEPS strobe
9-8	IEI	R/W	0h	Index event initialization of position counter 0h = Do nothing (action disabled) 1h = Do nothing (action disabled) 2h = Initializes the position counter on the rising edge of the QEPI signal (QPOSCNT = QPOSINIT) 3h = Initializes the position counter on the falling edge of QEPI signal (QPOSCNT = QPOSINIT)
7	SWI	R/W	0h	Software initialization of position counter 0h = Do nothing (action disabled) 1h = Initialize position counter, this bit is cleared automatically
6	SEL	R/W	0h	Strobe event latch of position counter 0h = The position counter is latched on the rising edge of QEPS strobe (QPOSSLAT = POSCCNT). Latching on the falling edge can be done by inverting the strobe input using the QSP bit in the QDECCTL register. 1h = Clockwise Direction: Position counter is latched on rising edge of QEPS strobe. Counter Clockwise Direction: Position counter is latched on falling edge of QEPS strobe.

Table 20-129. QEPCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5-4	IEL	R/W	0h	Index event latch of position counter (software index marker) 0h = Reserved 1h = Latches position counter on rising edge of the index signal 2h = Latches position counter on falling edge of the index signal 3h = Software index marker. Latches the position counter and quadrature direction flag on index event marker. The position counter is latched to the QPOSILAT register and the direction flag is latched in the QEPSTS[QDLF] bit. This mode is useful for software index marking.
3	PHEN	R/W	0h	Quadrature position counter enable/software reset 0h = Reset the eQEP peripheral internal operating flags/read-only registers. Control/configuration registers are not disturbed by a software reset. 1h = eQEP position counter is enabled
2	QCLM	R/W	0h	eQEP capture latch mode 0h = Latch on position counter read by CPU. Capture timer and capture period values are latched into QCTMRLAT and QCPRDLAT registers when CPU reads the QPOSCNT register. 1h = Latch on unit time out. Position counter, capture timer and capture period values are latched into QPOSLAT, QCTMRLAT and QCPRDLAT registers on unit time out.
1	UTE	R/W	0h	eQEP unit timer enable 0h = Disable eQEP unit timer 1h = Enable unit timer
0	WDE	R/W	0h	eQEP watchdog enable 0h = Disable the eQEP watchdog timer 1h = Enable the eQEP watchdog timer

20.4.3.14 QCAPCTL Register (offset = 2Ch) [reset = 0h]

QCAPCTL is shown in Figure 20-163 and described in Table 20-130.

Universal Asynchronous Receiver/Transmitter (UART)

This chapter describes the UART of the device.

Topic **Page**

21.1 Introduction

21.1.1 UART Mode Features

The general features of the UART/IrDA module when operating in UART mode are:

- 16C750 compatibility
- Baud rate from 300 bps up to 3.6864 Mbps
- Auto-baud between 1200 bps and 115.2 Kbps
- Software/Hardware flow control
  - Programmable Xon/Xoff characters
  - Programmable Auto-RTS and Auto CTS
- Programmable serial interface characteristics
  - 5, 6, 7, or 8-bit characters
  - Even, odd, mark (always 1), space (always 0), or no parity (non-parity bit frame) bit generation and detection
  - 1, 1.5, or 2 stop bit generation
- False start bit detection
- Line break generation and detection
- Modem control functions (CTS, RTS, DSR, DTR, RI, and DCD)
- Fully prioritized interrupt system controls
- Internal test and loopback capabilities

21.1.2 IrDA Mode Features

The general features of the UART/IrDA when operating in IrDA mode are:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR) and fast infrared (FIR) communications (very fast infrared (VFIR) is not supported)
- Frame formatting: addition of variable xBOF characters and EOF characters
- Uplink/downlink CRC generation/detection
- Asynchronous transparency (automatic insertion of break character)
- 8-entry status FIFO (with selectable trigger levels) available to monitor frame length and frame errors
- Framing error, cyclic redundancy check (CRC) error, illegal symbol (FIR), abort pattern (SIR, MIR) detection

21.1.3 CIR Mode Features

The general features of the UART/IrDA when operating in CIR mode are:

- Support of consumer infrared (CIR) for remote control applications
- Transmit and receive
- Free data format (supports any remote control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3 or 1/4 carrier duty cycle

21.1.4 Unsupported UART Features

The following UART/IrDA module features are not supported in this device.

Table 21-1. Unsupported UART Features

Feature	Reason
Full modem control on UART0	DCD, DSR, DTR, RI not pinned-out
Full modem control on UART2-5	DCD, DSR, DTR, RI not pinned-out
Device wake-up on UART1-5	Wake-up not supported - no SWake connection

21.2 Integration

This device contains 6 instantiations of the UART/IrDA (UARTIRDAOCP) peripheral. There are six UART modules called UART0 – UART5. UART0 provides wakeup capability. Only UART 1 provides full modem control signals. All UARTs support IrDA and CIR modes and RTS/CTS flow control (subject to pin muxing configuration). Figure 21-1 shows an example of system connectivity using UART communication with hardware handshake.

Figure 21-1. UART/IrDA Module — UART Application

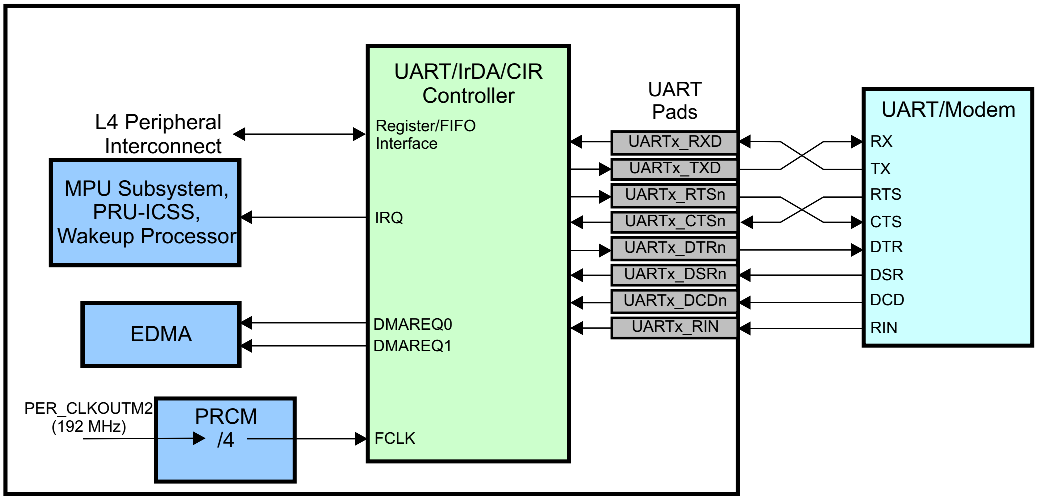

Figure 21-2 shows an example of system connectivity using infrared communication with remote control (consumer infrared).

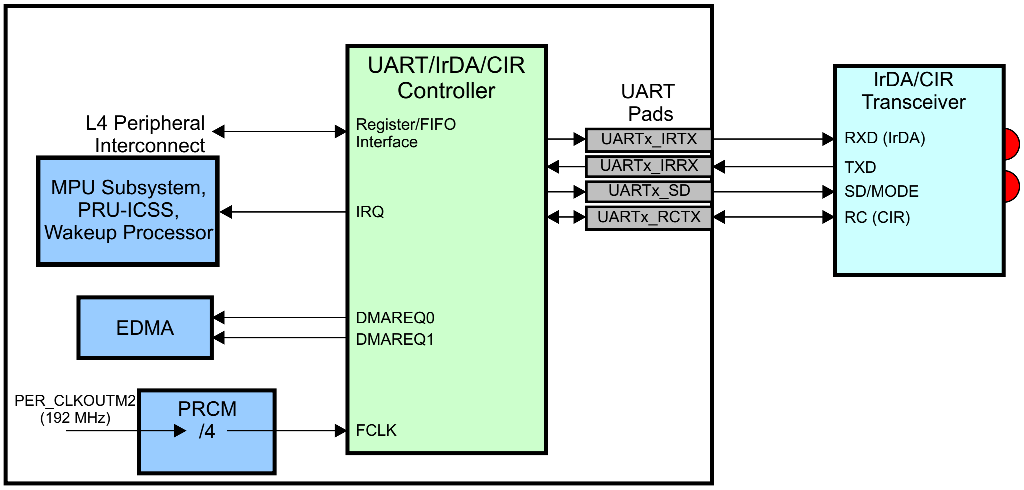
Figure 21-2. UART/IrDA Module — IrDA/CIR Application



21.2.1 UART Connectivity Attributes

The general connectivity attributes for each of the UART modules are shown in Table 21-2 and Table 21-3.

Table 21-2. UART0 Connectivity Attributes

Attributes	Type
Power Domain	Wake-Up Domain
Clock Domain	PD_WKUP_L4_WKUP_GCLK (OCP) PD_WKUP_UART0_GFCLK (Func)

Table 21-2. UART0 Connectivity Attributes (continued)

Attributes	Type
Reset Signals	WKUP_DOM_RST_N
Idle/Wakeup Signals	Smart Idle / Wakeup
Interrupt Requests	1 interrupt to MPU Subsystem (UART0INT), PRU-ICSS (nirq) and Wakeup Processor SWakeup to Wakeup Processor
DMA Requests	2 DMA requests to EDMA (TX – UTXEVT0, RX – URXEVT0)
Physical Address	L4 Wakeup slave port

Table 21-3. UART1–5 Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK (OCP) PD_PER_UART_GFCLK (Func)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	UART1-2 1 interrupt per instance to MPU Subsystem (UART1INT, UART2INT) and PRU-ICSS (nirq) UART3-5 1 interrupt per instance to only MPU Subsystem (UART3INT, UART4INT, UART5INT)
DMA Requests	2 DMA requests per instance to EDMA (TX – UTXEVTx, RX – URXEVTx)
Physical Address	L4 Peripheral slave port

21.2.2 UART Clock and Reset Management

The UART modules use separate functional and bus interface clocks.

Table 21-4. UART0 Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
CLK Interface clock From PRCM	26 MHz	M_OSC_CLK	pd_wkup_l4_wkup_gclk
FCLK Functional clock From PRCM	48 MHz	PER_CLKOUTM2 / 4	pd_wkup_uart0_gfclk

Table 21-5. UART1–5 Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
CLK Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk From PRCM
FCLK Functional clock	48 MHz	PER_CLKOUTM2 / 4	pd_per_uart_gfclk From PRCM

For UART operation, the functional clock is used to produce a baud rate up to 3.6M bits/s. Table 21-6 lists the supported baud rates, the requested divider, and the corresponding error versus the standard baud rate.

Table 21-6. UART Mode Baud and Error Rates

Baud rate	Over sampling	Divisor	Error (%)
300	16	10000	0
600	16	5000	0
1200	16	2500	0
2400	16	1250	0
4800	16	625	0
9600	16	313	0.16
14400	16	208	0.16
19200	16	156	0.16
28800	16	104	0.16
38400	16	78	0.16
57600	16	52	0.16
115200	16	26	0.16
230400	16	13	0.16
460800	13	8	0.16
921600	13	4	0.16
1843200	13	2	0.16
3000000	16	1	0
3686400	13	1	0.16

For IrDA operation, the internal functional clock divisor allows generation of SIR, MIR, or FIR baud rates as shown in Table 21-7.

Table 21-7. IrDA Mode Baud and Error Rates

Baud rate	IR mode	Encoding	Divisor	Error (%)
2400	SIR	3/16	1250	0
9600	SIR	3/16	312	0.16
19200	SIR	3/16	156	0.16
38400	SIR	3/16	78	0.16
57600	SIR	3/16	52	0.16
115200	SIR	3/16	26	0.16
576000	MIR	1/4	2	0
1152000	MIR	1/4	1	0
4000000	FIR	4PPM	1	0

21.2.3 UART Pin List

The UART interface pins are listed in Table 21-8. Pin functionality depends on the selected operating mode of the module.

Table 21-8. UART Pin List

Pin	Type	Description
UARTx_RXD / IRRX / RCRX	I	UART / IrDA / CIR Receive Data
UARTx_TXD / IRTX / RCTX	O/Z	UART / IrDA / CIR Transmit Data
UARTx_RTSn / SD	O/Z	UART Request to Send / IrDA Mode
UARTx_CTSn	I	UART Clear to Send
UARTx_DTRn(1)	O/Z	UART Data Terminal Ready
UARTx_DSRn(1)	I	UART Data Set Ready
UARTx_DCDn(1)	I	UART Data Carrier Detect
UARTx_RIn(1)	I	UART Ring Indicator

(1) UART1 only

The UART module can operate in three different modes based on the MODE_SELECT bits. The signal muxing based on these mode bits is shown in Table 21-9.

Table 21-9. UART Muxing Control

UARTx_TXD / IRTX / RCTX Function	UARTx_RXD / IRRX / RCRX Function	UARTx_RTSn / SD Function	UARTx_CTSn Function	Mode
TXD	RXD	RTSn	CTSn	UART
IRTX	IRRX	SD	not used	IrDA (SIR, MIR, FIR)
RCTX	RCRX	SD	not used	CIR

21.3 Functional Description

21.3.1 Block Diagram

The UART/IrDA/CIR module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two modes:

- Function mode: Routes the data to the chosen function (UART, IrDA, or CIR) and enables the mechanism corresponding to the chosen function
- Register mode: Enables conditional access to registers

For more information about mode configuration, see Section 21.3.7, *Mode Selection*.

Protocol formatting has three subcategories:

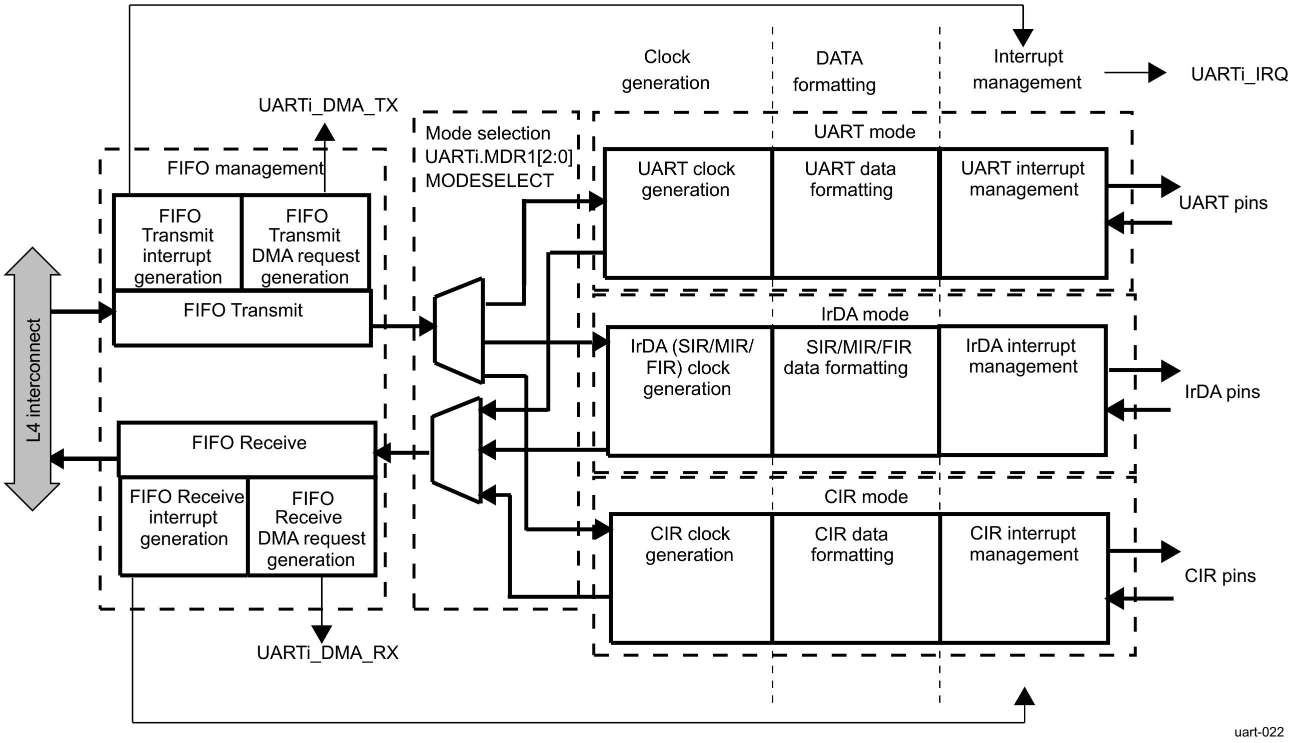
- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine that is responsible for the transition between FIFO data and frame data associated with it.
- Interrupt management: Different interrupt types are generated depending on the chosen function:
  - UART mode interrupts: Seven interrupts prioritized in six different levels
  - IrDA mode interrupts: Eight interrupts. The interrupt line is activated when any interrupt is generated (there is no priority).
  - CIR mode interrupts: A subset of existing IrDA mode interrupts is used.

  In each mode, when an interrupt is generated, the UART_IIR register indicates the interrupt type.

In parallel with these functional blocks, a power-saving strategy exists for each function.

Figure 21-3 is the UART/IrDA/CIR block diagram.

Figure 21-3. UART/IrDA/CIR Functional Specification Block Diagram



21.3.2 Clock Configuration

Each UART uses a 48-MHz functional clock for its logic and to generate external interface signals. Each UART uses an interface clock for register accesses. The PRCM module generates and controls all these clocks (for more information, see *Clock Domain Module Attributes*, in Chapter 6, *Power, Reset, and Clock Management*).

The idle and wake-up processes use a handshake protocol between the PRCM and the UART (for a description of the protocol, see *Module-Level Clock Management* in Chapter 6, *Power, Reset, and Clock Management*). The UARTi.UART_SYSC[4:3] IDLEMODE bit field controls UART idle mode.

21.3.3 Software Reset

The UARTi.UART_SYSC[1] SOFTRESET bit controls the software reset; setting this bit to 1 triggers a software reset functionally equivalent to hardware reset.

21.3.4 Power Management

21.3.4.1 UART Mode Power Management

21.3.4.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UARTi.UART_IER[4] SLEEP_MODE bit to 1 (when the UARTi.UART_EFR[4] ENHANCED_EN bit is set to 1).

Sleep mode is entered when all the following conditions exist:

- The serial data input line, uarti_rx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- The only pending interrupts are THR interrupts.

Sleep mode is a good way to lower UART power consumption, but this state can be achieved only when the UART is set to modem mode. Therefore, even if the UART has no key role functionally, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked by these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the uarti_rx line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the UARTi.UART_SCR[4] RX_CTS_WU_EN bit to 1. To understand how to manage the interrupt, see Section 21.3.5.2, *Wake-Up Interrupt*.

NOTE: There must be no writing to the divisor latches, UARTi.UART_DLL and UARTi.UART_DLH, to set the baud clock (BCLK) while in sleep mode. It is advisable to disable sleep mode using the UARTi.UART_IER[4] SLEEP_MODE bit before writing to the UARTi.UART_DLL register or the UARTi.UART_DLH register.

21.3.4.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. Power-reduction techniques can be applied at the system level by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol used at the system level to shut down the UART clocks in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the UARTi.UART_SYSC[2] ENAWAKEUP bit and the UARTi.UART_WER register).

For more information, see *Module Level Clock Management* in Chapter 6, *Power, Reset, and Clock Management*.

21.3.4.2 IrDA/CIR Mode Power Management

21.3.4.2.1 Module Power Saving

In IrDA/CIR modes, sleep mode is enabled by setting the UARTi.MDR[3] IR_SLEEP bit to 1.

Sleep mode is entered when all the following conditions exist:

- The serial data input line, uarti.rx_irrx, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the uarti_rx_irrx line or when data is written to the TX FIFO.

21.3.4.2.2 System Power Saving

System power saving for the IrDA/CIR mode has the same function as for the UART mode (see Section 21.3.4.1.2, *System Power Saving*).

21.3.4.3 Local Power Management

Table 21-10 describes power-management features available for the UART.

NOTE: For information about source clock gating and sleep/wake-up transitions description, see *Module-Level Clock Management* in Chapter 6, *Power, Reset, and Clock Management*.

Table 21-10. Local Power-Management Features

Feature	Registers	Description
Clock autogating	UART_SYSC[0] AUTOIDLE	This bit allows local power optimization in the module by gating the UARTi_ICLK clock on interface activity or gating the UARTi_FCLK clock on internal activity.
Slave idle modes	UART_SYSC[4:3] IDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	UART_SYSC[2] ENAWAKEUP	This bit enables the wake-up feature at module level.
Wake-Up sources enable	N/A	Feature not available

21.3.5 Interrupt Requests

The UART IrDA CIR module generates interrupts. All interrupts can be enabled/disabled by writing to the appropriate bit in the interrupt enable register (IER). The interrupt status of the device can be checked at any time by reading the interrupt identification register (IIR). The UART, IrDA, and CIR modes have different interrupts in the UART IrDA CIR module and therefore have different IER and IIR mappings according to the selected mode.

21.3.5.1 UART Mode Interrupt Management

21.3.5.1.1 UART Interrupts

UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UARTi.UART_IIR) sets the UARTi.UART_IIR[0] IT_PENDING bit to 0 to indicate that an interrupt is pending, and indicates the type of interrupt through the UARTi.UART_IIR[5:1] bit field. Table 21-11 summarizes the interrupt control functions.

Table 21-11. UART Mode Interrupts

UART_IIR[5:0]	Priority Level	Interrupt Type	Interrupt Source	Interrupt Reset Method
000001	None	None	None	None
000110	1	Receiver line status	OE, FE, PE, or BI errors occur in characters in the RX FIFO.	FE, PE, BI: Read the UART_RHR register. OE: Read the UART_LSR register.
001100	2	RX time-out	Stale data in RX FIFO	Read the UART_RHR register.
000100	2	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read the UART_RHR register until the interrupt condition disappears.
000010	3	THR interrupt	TFE (UART_THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to the UART_THR until the interrupt condition disappears.
000000	4	Modem status	See the UART_MSR register.	Read the UART_MSR register.
010000	5	XOFF interrupt/special character interrupt	Receive XOFF characters/special character	Receive XON character(s), if XOFF interrupt/read of the UART_IIR register, if special character interrupt.
100000	6	CTS, RTS, DSR	RTS pin or CTS pin or DSR change state from active (low) to inactive (high).	Read the UART_IIR register.

For the receiver-line status interrupt, the RX_FIFO_STS bit (UARTi.UART_LSR[7]) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UARTi.UART_IIR register.

21.3.5.2 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that works differently from other interrupts. This interrupt is enabled when the UARTi.UART_SCR[4] RXCTSDSRWAKEUPENABLE bit is set to 1. The UARTi.UART_IIR register is not modified when this occurs; the UARTi.UART_SSR[1] RXCTSDSRWAKEUPSTS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, it can be cleared only by resetting the UARTi.UART_SCR[4] RXCTSDSRWAKEUPENABLE bit. This bit must be re-enabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

A wake-up interrupt can also occur if the WER[7] TXWAKEUPEN bit is set to 1 and one of the following occurs:

- THR interrupt occurred if it is enabled (omitted if TX DMA request is enabled).
- TX DMA request occurred if it is enabled.
- TX_STATUS_IT occurred if it is enabled (only IrDA and CIR modes). Cannot be used with THR interrupt.

CAUTION

Wake-Up interface implementation in IrDA mode is based on the UARTi_SIDLEACK low-to-high transition instead of the UARTi_SIDLEACK state.

This does not ensure wake-up event generation as expected when configured in smart-idle mode, and the system wakes up for a short period.

21.3.5.3 IrDA Mode Interrupt Management

21.3.5.3.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UARTi.UART_IER). The interrupt status of the device can be checked by reading the interrupt identification register (UARTi.UART_IIR).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UARTi.UART_IER and UARTi.UART_IIR mappings, depending on the selected mode.

IrDA modes have eight possible interrupts (see Table 21-12). The interrupt line is activated when any interrupt is generated (there is no priority).

Table 21-12. IrDA Mode Interrupts

UART_IIR Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read the UART_RHR register until the interrupt condition disappears.
1	THR interrupt	TFE (UART_THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to the UART_THR until the interrupt condition disappears.

Table 21-12. IrDA Mode Interrupts (continued)

UART_IIR Bit	Interrupt Type	Interrupt Source	Interrupt Reset Method
2	Last byte in RX FIFO	Last byte of frame in RX FIFO is available to be read at the RHR port.	Read the UART_RHR register.
3	RX overrun	Write to the UART_RHR register when the RX FIFO is full.	Read UART_RESUME register.
4	Status FIFO interrupt	Status FIFO triggers level reached.	Read STATUS FIFO.
5	TX status	1. UART_THR empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error. OR 2. Transmission of the last bit of the IrDA frame completed successfully.	1. Read the UART_RESUME register. OR 2. Read the UART_IIR register.
6	Receiver line status interrupt	CRC, ABORT, or frame-length error is written into the STATUS FIFO.	Read the STATUS FIFO (read until empty - maximum of eight reads required).
7	Received EOF	Received end-of-frame	Read the UART_IIR register.

21.3.5.4 CIR Mode Interrupt Management

21.3.5.4.1 CIR Interrupts

The CIR function generates interrupts that can be enabled and disabled by writing to the appropriate bit in the interrupt enable register (UARTi.UART_IER). The interrupt status of the device can be checked by reading the interrupt identification register (UARTi.UART_IIR).

UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UARTi.UART_IER and UARTi.UART_IIR mappings, depending on the selected mode.

Table 21-13 lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UARTi.UART_IIR[5] bit is to indicate that the last bit of infrared data was passed to the uart_cts_rctx pin.

Table 21-13. CIR Mode Interrupts

UART_IIR Bit Number	Interrupt Type	Interrupt Source	Interrupt Reset Method
0	RHR interrupt	DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable)	Read UART_RHR until interrupt condition disappears.
1	THR interrupt	TFE (UART_THR empty) (FIFO disable) TX FIFO below trigger level (FIFO enable)	Write to the UART_THR register until the interrupt condition disappears.
2	RX_STOP_IT	Receive stop interrupt (depending on value set in the BOF Length Register (UART_EBLR).	Read IIR
3	RX overrun	Write to RHR when RX FIFO is full.	Read RESUME register.
4	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
5	TX status	Transmission of the last bit of the frame is complete successfully.	Read the UART_IIR register.
6	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode
7	N/A for CIR mode	N/A for CIR mode	N/A for CIR mode

21.3.6 FIFO Management

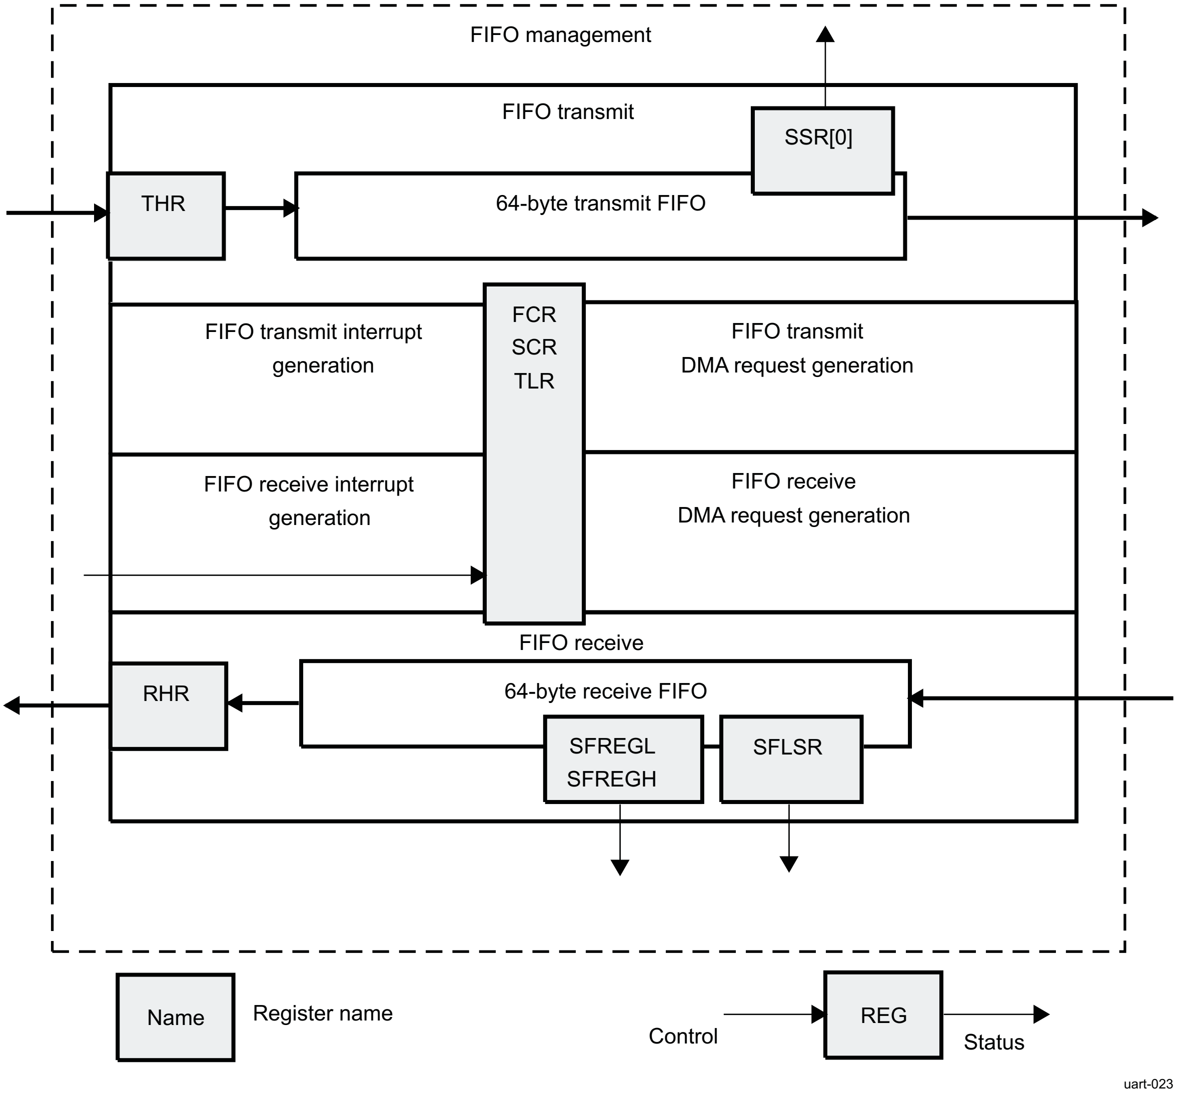
The FIFO is accessed by reading and writing the UARTi.UART_RHR and UARTi.UART_THR registers. Parameters are controlled using the FIFO control register (UARTi.UART_FCR) and supplementary control register (UARTi.UART_SCR). Reading the UARTi.UART_SSR[0] TX_FIFO_FULL bit at 1 means the FIFO is full.

The UARTi.UART_TLR register controls the FIFO trigger level, which enables DMA and interrupt generation. After reset, transmit (TX) and receive (RX) FIFOs are disabled; thus, the trigger level is the default value of 1 byte. Figure 21-4 shows the FIFO management registers.

NOTE: Data in the UARTi.UART_RHR register is not overwritten when an overflow occurs.

NOTE: The UARTi.UART_SFLSR, UARTi.UART_SFREGL, and UARTi.UART_SFREGH status registers are used in IrDA mode only. For use, see Section 21.3.8.2.6, *IrDA Data Formatting*.

Figure 21-4. FIFO Management Registers



21.3.6.1 FIFO Trigger

21.3.6.1.1 Transmit FIFO Trigger

Table 21-14 lists the TX FIFO trigger level settings.

Table 21-14. TX FIFO Trigger Level Setting Summary

UART_SCR[6]	UART_TLR[3:0]	TX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field (8,16, 32, or 56 spaces)
0	!= 0x0	Defined by the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field (from 4 to 60 spaces with a granularity of 4 spaces)
1	Value	Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space) **Note:** The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of one space required). All zeros result in unpredictable behavior.

21.3.6.1.2 Receive FIFO Trigger

Table 21-15 lists the RX FIFO trigger level settings.

Table 21-15. RX FIFO Trigger Level Setting Summary

UART_SCR[7]	UART_TLR[7:4]	RX FIFO Trigger Level
0	= 0x0	Defined by the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field (8,16, 56, or 60 characters)
0	!= 0x0	Defined by the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA bit field (from 4 to 60 characters with a granularity of 4 characters)
1	Value	Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character) **Note:** The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of one character required). All zeros result in unpredictable behavior.

The receive threshold is programmed using the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START and UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit fields:

- Trigger levels from 0 to 60 bytes are available with a granularity of 4 (trigger level = 4 x [4-bit register value]).
- To ensure correct device operation, ensure that RX_FIFO_TRIG_HALT RX_FIFO_TRIG when auto-RTS is enabled.

  Delay = [4 + 16 x (1 + CHAR_LENGTH + Parity + Stop 0.5)] x Baud_rate + 4 x FCLK

  NOTE: The RTS signal is deasserted after the UART module receives the data over RX_FIFO_TRIG_HALT. Delay means how long the UART module takes to deassert the RTS signal after reaching RX_FIFO_TRIG_HALT.

- In FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the RX FIFO trigger level (the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG bit field); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

21.3.6.2 FIFO Interrupt Mode

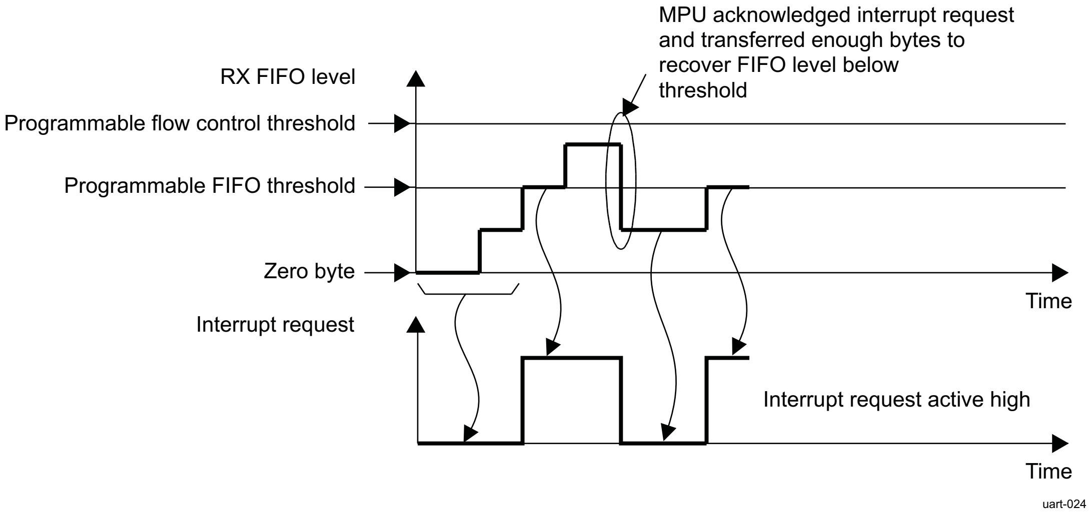
In FIFO interrupt mode (the FIFO control register UARTi.UART_FCR[0] FIFO_EN bit is set to 1 and relevant interrupts are enabled by the UARTi.UART_IER register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the RX/TX FIFO threshold (the UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA and UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit fields or the UARTi.UART_FCR[7:6] RX_FIFO_TRIG and UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit fields, respectively) is reached.

The interrupt signals instruct the MPU to transfer data to the destination (from the UART in receive mode and/or from any source to the UART FIFO in transmit mode).

When UART flow control is enabled with interrupt capabilities, the UART flow control FIFO threshold (the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field) must be greater than or equal to the RX FIFO threshold.

Figure 21-5 shows the generation of the RX FIFO interrupt request.

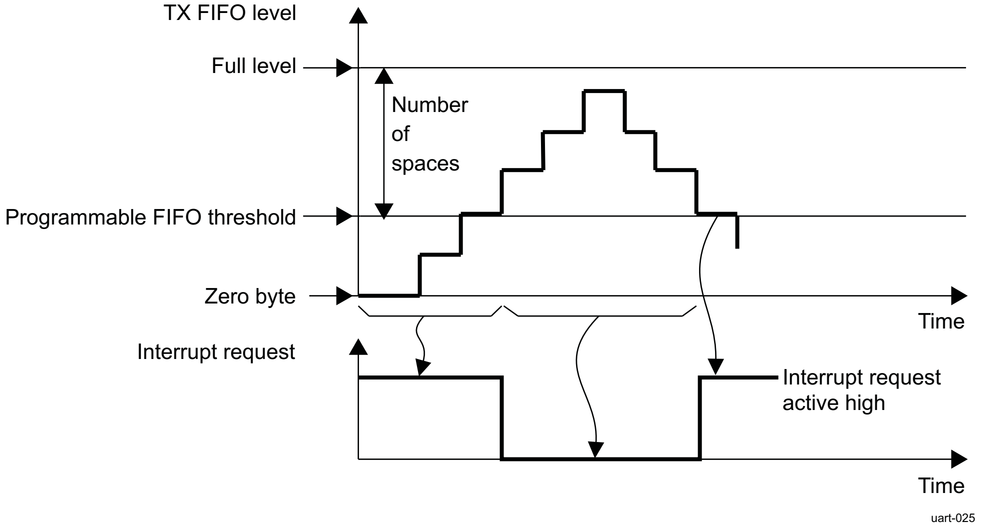
Figure 21-5. RX FIFO Interrupt Request Generation



In receive mode, no interrupt is generated until the RX FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the MPU has handled enough bytes to put the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 21-6 shows the generation of the TX FIFO interrupt request.

Figure 21-6. TX FIFO Interrupt Request Generation



In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

21.3.6.3 FIFO Polled Mode Operation

In FIFO polled mode (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0 and the relevant interrupts are disabled by the UARTi.UART_IER register), the status of the receiver and transmitter can be checked by polling the line status register (UARTi.UART_LSR).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the MPU.

21.3.6.4 FIFO DMA Mode Operation

Although DMA operation includes four modes (DMA modes 0 through 3), assume that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

DMA requests in mode 2 and mode 3 use the following signals:

- S_DMA_48
- S_DMA_50
- S_DMA_52/D_DMA_10
- S_DMA_54

The following signals are not used by the module in mode 2 and mode 3:

- S_DMA_49
- S_DMA_51
- S_DMA_53/D_DMA_11
- S_DMA_55

These signals can be selected as follows:

- When the UARTi.UART_SCR[0] DMA_MODE_CTL bit is set to 0, setting the UARTi.UART_FCR[3]DMA_MODE bit to 0 enables DMA mode 0. Setting the DMA_MODE bit to 1 enables DMA mode 1.
- When the DMA_MODE_CTL bit is set to 1, the UARTi.UART_SCR[2:1]DMA_MODE_2 bit field determines DMA mode 0 to mode 3 based on the supplementary control register (UART_SCR) description.

For example:

- If no DMA operation is desired, set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 bit field to 0x0. (The DMA_MODE bit is discarded.)
- If DMA mode 1 is desired, set the DMA_MODE_CTL bit to 0 and the DMA_MODE bit to 1, or set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 bit field to 01. (The DMA_MODE bit is discarded.)

If the FIFOs are disabled (the UARTi.UART_FCR[0] FIFO_EN bit is set to 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

Depending on UART_MDR3[2] SET_DMA_TX_THRESHOLD, the threshold can be programmed different ways:

- SET_TX_DMA_THRESHOLD = 1:

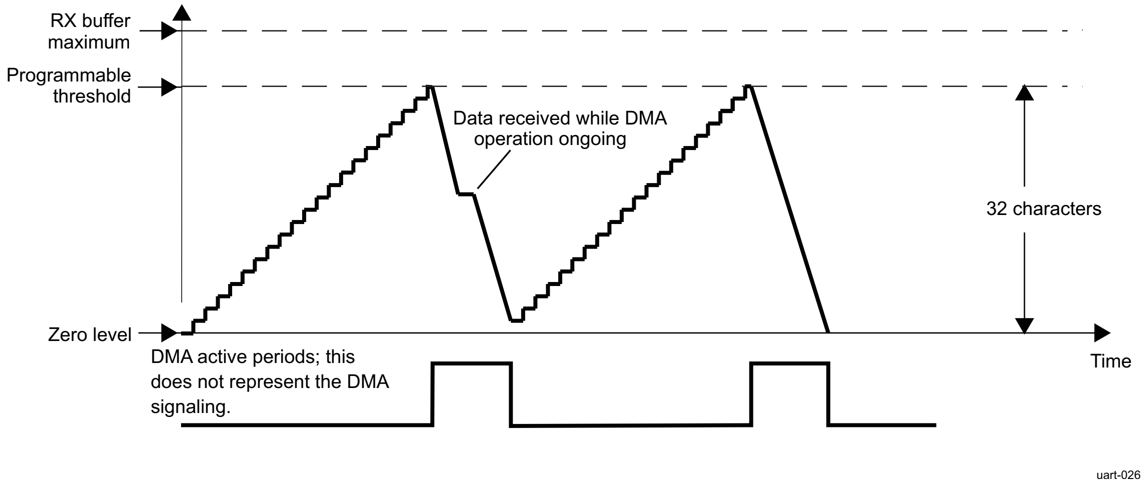
  The threshold value will be the value of the UART_TX_DMA_THRESHOLD register. If SET_TX_DMA_THRESHOLD + TX trigger spaces 64, then the default method of threshold is used: threshold value = TX FIFO size.
- SET_TX_DMA_THRESHOLD = 0:

  The threshold value = TX FIFO size - TX trigger space. The TX DMA line is asserted if the TX FIFO level is lower then the threshold. It remains asserted until TX trigger spaces number of bytes are written into the FIFO. The DMA line is then deasserted and the FIFO level is compared with the threshold value.

21.3.6.4.1 DMA Transfers (DMA Mode 1, 2, or 3)

Figure 21-7 through Figure 21-10 show the supported DMA operations.

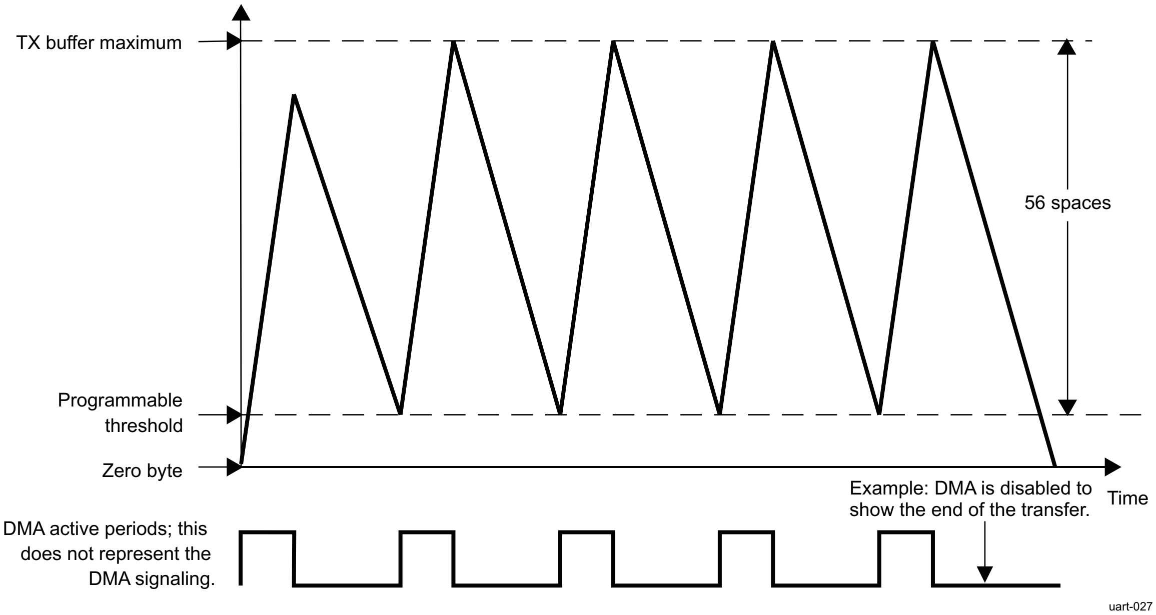
Figure 21-7. Receive FIFO DMA Request Generation (32 Characters)



In receive mode, a DMA request is generated when the RX FIFO reaches its threshold level defined in the trigger level register (UARTi.UART_TLR). This request is deasserted when the number of bytes defined by the threshold level is read by the sDMA.

In transmit mode, a DMA request is automatically asserted when the TX FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the UARTi.UART_TLR register is written by the sDMA. If an insufficient number of characters is written, the DMA request stays active.

Figure 21-8. Transmit FIFO DMA Request Generation (56 Spaces)



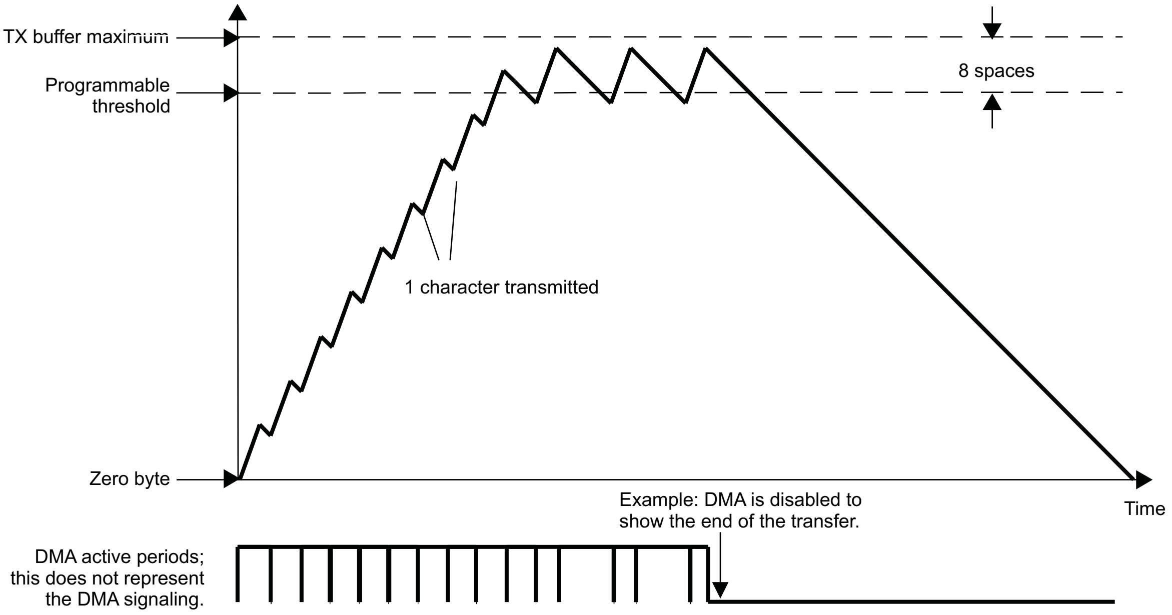
The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UARTi.UART_TLR register.

The threshold can be programmed in a number of ways. Figure 21-8 shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UARTi.UART_FCR[5:4] TX_FIFO_TRIG bit field or the UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA bit field concatenated with the TX_FIFO_TRIG bit field.

The setting of 56 spaces in the UART/IrDA/CIR module must correlate with the settings of the sDMA so that the buffer does not overflow (program the DMA request size of the LH controller to equal the number of spaces in the UART/IrDA/CIR module).

Figure 21-9 shows an example with eight spaces to show the buffer level crossing the space threshold. The LH DMA controller settings must correspond to those of the UART/IrDA/CIR module.

Figure 21-9. Transmit FIFO DMA Request Generation (8 Spaces)



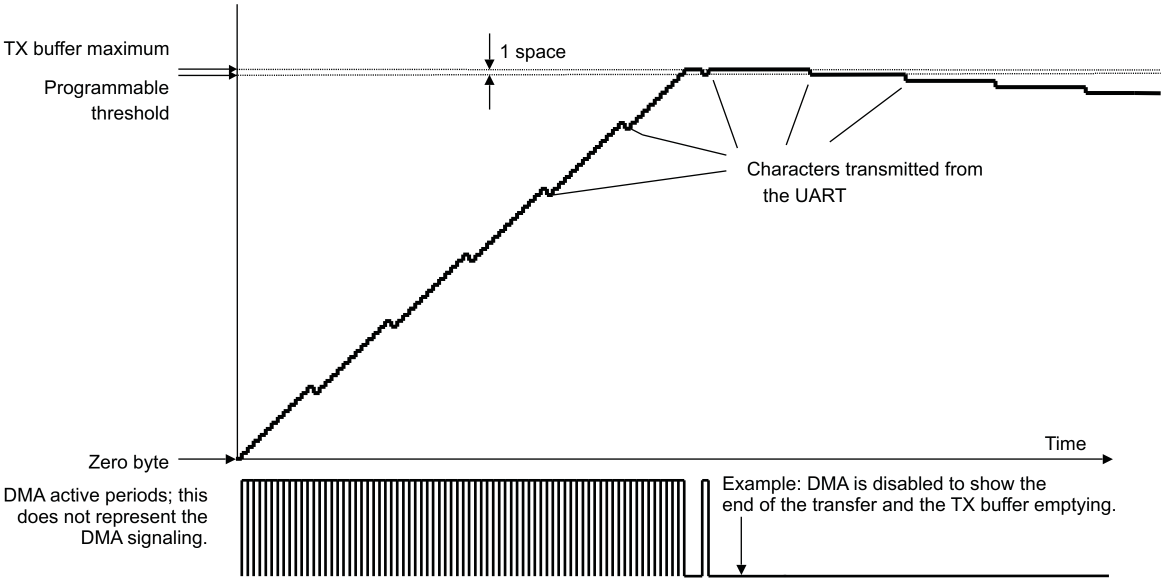
uart-028

The next example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see Figure 21-10). The buffer is filled faster than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions, the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UARTi.UART_DLL and UARTi.UART_DLH registers.

The DMA settings must correspond to the system LH DMA controller settings to ensure correct operation of this logic.

Figure 21-10. Transmit FIFO DMA Request Generation (1 Space)



uart-029

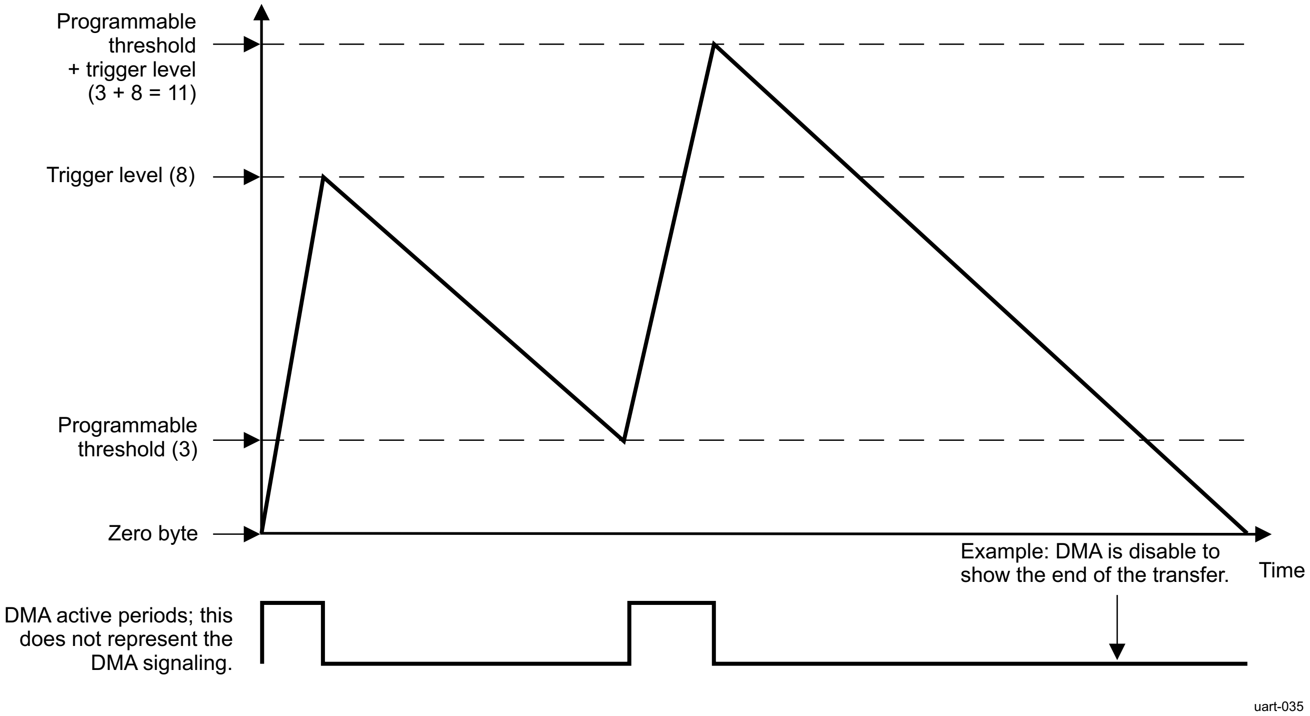
The final example shows the setting of eight spaces, but setting the TX DMA threshold directly by setting the UART_MDR3[1]SET_DMA_RX_THRESHOLD bit and the UART_TX_DMA_THRESHOLD register (see Figure 21-11). In the example, UART_TX_DMA_THRESHOLD[2:0]TX_DMA_THRESHOLD = 3 and the trigger level is 8. The buffer is filled at a faster rate than the baud rate transmits data to the TX pin. The buffer is filled with 8 bytes and the DMA operations stop transferring data to the transmit buffer. When the buffer is emptied to the threshold level by transmission, the DMA operation activates again to fill the buffer with 8 bytes.

Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UART_DLL and UART_DLH registers.

If the selected threshold level plus the trigger level exceed the maximum buffer size, the original TX DMA threshold method is used to prevent TX overrun, regardless of the value of the UART_MDR3[1]SET_DMA_RX_THRESHOLD bit.

The DMA settings must correspond to the settings of the system local host DMA controller to ensure the correct operation of this logic.

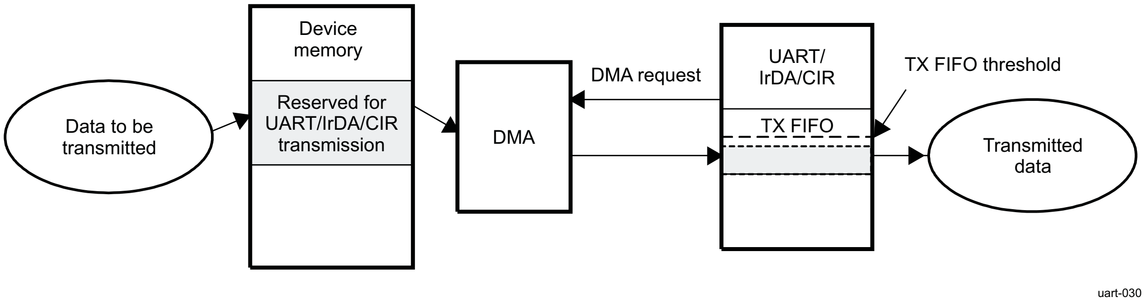
Figure 21-11. Transmit FIFO DMA Request Generation Using Direct TX DMA Threshold Programming. (Threshold = 3; Spaces = 8)



21.3.6.4.2 DMA Transmission

Figure 21-12 shows DMA transmission.

Figure 21-12. DMA Transmission



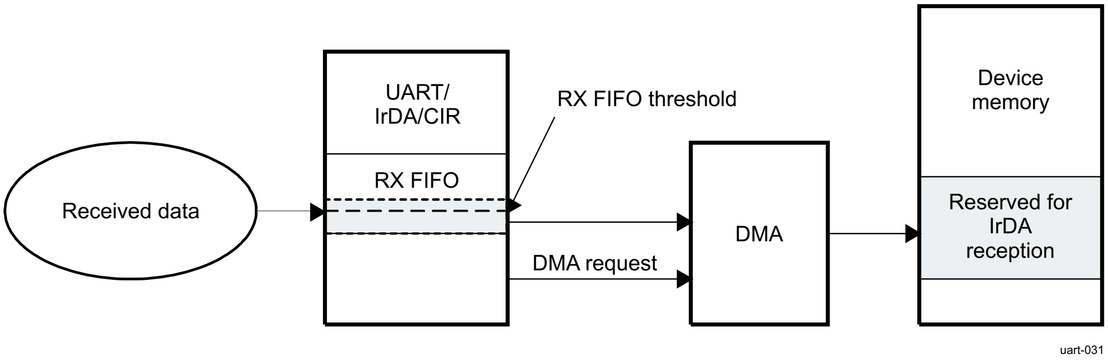
1. Data to be transmitted are put in the device memory reserved for UART/IrDA/CIR transmission by the DMA:
   a. Until the TX FIFO trigger level is not reached, a DMA request is generated
   b. An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
2. Data in the TX FIFO are automatically transmitted.
3. The end of the transmission is signaled by the UARTi.UART_THR empty (TX FIFO empty).

NOTE: In IrDA mode, the transmission does not end immediately after the TX FIFO empties, at which point the last data byte, the CRC field, and the stop flag still must be transmitted; thus, the end of transmission occurs a few milliseconds after the UARTi.UART_THR register empties.

21.3.6.4.3 *DMA Reception*

Figure 21-13 shows DMA reception.

Figure 21-13. DMA Reception



1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA:
   a. At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
   b. An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

21.3.7 Mode Selection

21.3.7.1 Register Access Modes

21.3.7.1.1 *Operational Mode and Configuration Modes*

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only for initialization or reconfiguration of the module.

The value of the UARTi.UART_LCR register determines the register access mode (see Table 21-16).

Table 21-16. UART/IrDA/CIR Register Access Mode Programming (Using UART_LCR)

Mode	Condition
Configuration mode A	UART_LCR[7] = 0x1 and UART_LCR[7:0] != 0xBF
Configuration mode B	UART_LCR[7] = 0x1 and UART_LCR[7:0] = 0xBF
Operational mode	UART_LCR[7] = 0x0

21.3.7.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional on the programming of a submode (MSR_SPR, TCR_TLR, and XOFF).

Table 21-17 through Table 21-19 summarize the register access submodes.

Table 21-17. Subconfiguration Mode A Summary

Mode	Condition
MSR_SPR	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

Table 21-18. Subconfiguration Mode B Summary

Mode	Condition
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1
XOFF	(UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0)

Table 21-19. Suboperational Mode Summary

Mode	Condition
MSR_SPR	UART_EFR[4] = 0x0 or UART_MCR[6] = 0x0
TCR_TLR	UART_EFR[4] = 0x1 and UART_MCR[6] = 0x1

21.3.7.1.3 Registers Available for the Register Access Modes

Table 21-20 lists the names of the register bits in each access register mode. Gray shading indicates that the register does not depend on the register access mode (available in all modes).

Table 21-20. UART/IrDA/CIR Register Access Mode Overview

(1) MSR_SPR mode is active (see Section 21.3.7.1.2, *Register Access Submode*)

(2) TCR_TLR mode is active (see Section 21.3.7.1.2, *Register Access Submode*)

(3) XOFF mode is active (see Section 21.3.7.1.2, *Register Access Submode*)

21.3.7.2 UART/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UARTi.UART_MDR1[2:0] MODESELECT bit field (see Table 21-21).

Table 21-21. UART Mode Selection

Value	Mode
0x0:	UART 16x mode
0x1:	SIR mode
0x2:	UART 16x auto-baud
0x3:	UART 13x mode
0x4:	MIR mode
0x5:	FIR mode
0x6:	CIR mode

MODESELECT is effective when the module is in operational mode (see Section 21.3.7.1, *Register Access Modes*).

21.3.7.2.1 Registers Available for the UART Function

Only the registers listed in Table 21-22 are used for the UART function.

Table 21-22. UART Mode Register Overview[1] [2]

Address Offset	Registers					
	Configuration Mode A		Configuration Mode B		Operational Mode

21.3.8 Protocol Formatting

The UART/IRDA module can operate in seven different modes:

1. UART 16x mode (≤230.4 Kbits/s), UART16x ≤460Kbits/s if MDR3[1] is set
2. UART 16x mode with autobauding (≥1200 bits/s and ≤115.2 Kbits/s) if MDR3[1] is not set
3. UART 13x mode (≥460.8 Kbits/s) if MDR3[1] is not set
4. IrDA SIR mode (≤115.2 Kbits/s) if MDR3[1] is not set
5. IrDA MIR mode (0.576 and 1.152 Mbits/s) if MDR3[1] is not set
6. IrDA FIR mode (4 Mbits/s) if MDR3[1] is not set
7. CIR mode (programmable modulation rates specific to remote control applications) if MDR3[1] is not set

The module performs a serial-to-parallel conversion on received data characters and a parallel-to-serial conversion on transmitted data characters by the processor. The complete status of each channel of the module and each received character/frame can be read at any time during functional operation via the line status register (LSR).

The module can be placed in an alternate mode (FIFO mode) to relieve the processor of excessive software overhead by buffering received/transmitted characters.

Both the receiver and transmitter FIFOs can store up to 64 bytes of data (plus three additional bits of error status per byte for the receiver FIFO) and have selectable trigger levels. Both interrupts and DMA are available to control the data flow between the LH and the module.

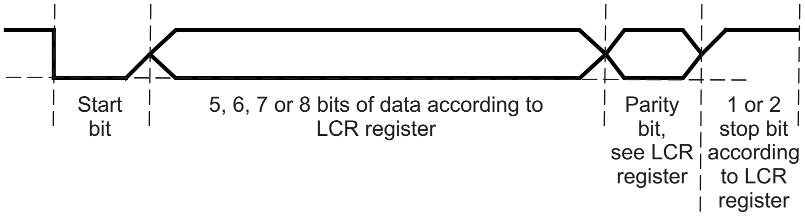
21.3.8.1 UART Mode

The UART uses a wired interface for serial communication with a remote device.

The UART module is functionally compatible with the TL16C750 UART and is also functionally compatible to earlier designs, such as the TL16C550. The UART module can use hardware or software flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals. Software flow control automatically controls data flow by using programmable XON/XOFF characters.

The UART modem module is enhanced with an autobauding functionality which in control mode allows to automatically set the speed, the number of bit per character, the parity selected.

Figure 21-14. UART Data Format

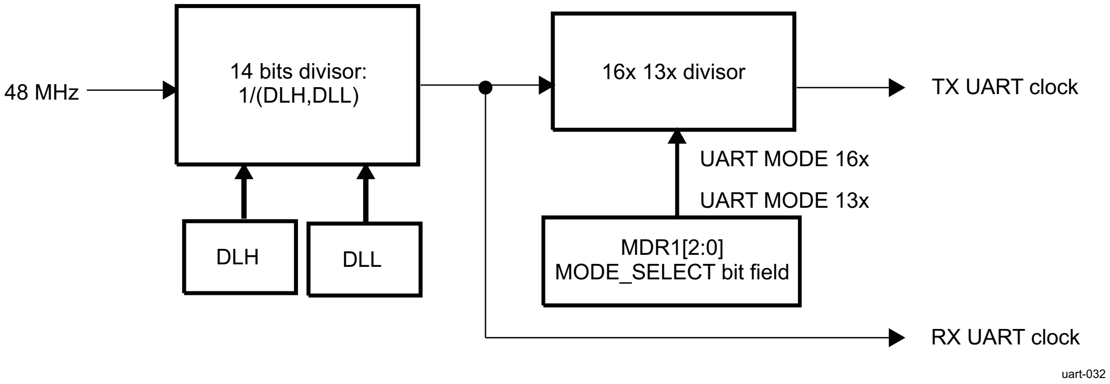


21.3.8.1.1 *UART Clock Generation: Baud Rate Generation*

The UART function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 21-15 shows the baud rate generator and associated controls.

Figure 21-15. Baud Rate Generation



CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART_DLH, UARTi.UART_DLL), MODE_SELECT = DISABLE (UARTi.UART_MDR1[2:0]) must be set to 0x7. Failure to observe this rule can result in unpredictable module behavior.

21.3.8.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency/(16x baud rate)
- UART 13x mode: Divisor value = Operating frequency/(13x baud rate)

Table 21-25 describes the UART baud rate settings.

Table 21-25. UART Baud Rate Settings (48-MHz Clock)

Baud Rate	Baud Multiple	DLH,DLL (Decimal)	DLH,DLL (Hex)	Actual Baud Rate	Error (%)

21.3.8.1.3 UART Data Formatting

The UART can use hardware flow control to manage transmission and reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART is enhanced with the autobauding function. In control mode, autobauding lets the speed, the number of bits per character, and the parity selected be set automatically.

21.3.8.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UARTi.UART_LCR register.

Character length is specified using the UARTi.UART_LCR[1:0] CHAR_LENGTH bit field.

The number of stop-bits is specified using the UARTi.UART_LCR[2] NB_STOP bit.

The parity bit is programmed using the UARTi.UART_LCR[5:3] PARITY_EN, PARITY_TYPE_1, and PARITY_TYPE_2 bit fields (see Table 21-26).

Table 21-26. UART Parity Bit Encoding

PARITY_EN	PARITY_TYPE_1	PARITY_TYPE_2	Parity
0	N/A	N/A	No parity
1	0	0	Odd parity
1	1	0	Even parity
1	0	1	Forced 1
1	1	1	Forced 0

21.3.8.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled and disabled independently by programming the UARTi.UART_EFR[7:6] AUTO_CTS_EN and AUTO_RTS_EN bit fields, respectively.

With auto-CTS, uarti_cts must be active before the module can transmit data.

Auto-RTS activates the uarti_rts output only when there is enough room in the RX FIFO to receive data. It deactivates the uarti_rts output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.UART_TCR register determine the levels at which uarti_rts is activated and deactivated.

If auto-CTS and auto-RTS are enabled, data transmission does not occur unless the RX FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the RX FIFO latency.

- Auto-RTS:

  Auto-RTS data flow control originates in the receiver block. The RX FIFO trigger levels used in auto-RTS are stored in the UARTi.UART_TCR register. uarti_rts is active if the RX FIFO level is below the HALT trigger level in the UARTi.UART_TCR[3:0] RX_FIFO_TRIG_HALT bit field. When the RX FIFO HALT trigger level is reached, uarti_rts is deasserted. The sending device (for example, another UART) can send an additional byte after the trigger level is reached because it may not recognize the deassertion of RTS until it begins sending the additional byte.

  uarti_rts is automatically reasserted when the RX FIFO reaches the RESUME trigger level programmed by the UARTi.UART_TCR[7:4] RX_FIFO_TRIG_START bit field. This reassertion requests the sending device to resume transmission.

  In this case, uarti_rts is an active-low signal.

- Auto-CTS:

  The transmitter circuitry checks uarti_cts before sending the next data byte. When uarti_cts is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, uarti_cts must be deasserted before the middle of the last stop-bit currently sent.

  The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the uarti_cts state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

  In this case, uarti_cts is an active-low signal.

21.3.8.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.UART_EFR) and the modem control register (UARTi.UART_MCR). Different combinations of software flow control can be enabled by setting different combinations of the UARTi.UART_EFR[3:0] bit field (see Table 21-27).

Two other enhanced features relate to software flow control:

- XON any function (UARTi.UART_MCR[5]): Operation resumes after receiving any character after the XOFF character is recognized. If special character detect is enabled and special character is received after XOFF1, it does not resume transmission. The special character is stored in the RX FIFO.

NOTE: The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UARTi.UART_EFR[5]): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.UART_IIR[4]) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.UART_IIR. The special character is transferred to the RX FIFO. Special character does not work with XON2, XOFF2, or sequential XOFFs.

Table 21-27. UART_EFR[3:0] Software Flow Control Options

Bit 3	Bit 2	Bit 1	Bit 0	TX, RX Software Flow Controls
0	0	X	X	No transmit flow control
1	0	X	X	Transmit XON1, XOFF1
0	1	X	X	Transmit XON2, XOFF2
1	1	X	X	Transmit XON1, XON2: XOFF1, XOFF2(1)
X	X	0	0	No receive flow control
X	X	1	0	Receiver compares XON1, XOFF1
X	X	0	1	Receiver compares XON2, XOFF2
X	X	1	1	Receiver compares XON1, XON2: XOFF1, XOFF2(1)

(1) In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.
XON1 is defined in the UARTi.UART_XON1_ADDR1[7:0] XON_WORD1 bit field. XON2 is defined in the UARTi.UART_XON2_ADDR2[7:0] XON_WORD2 bit field.
XOFF1 is defined in the UARTi.UART_XOFF1[7:0] XOFF_WORD1 bit field. XOFF2 is defined in the UARTi.UART_XOFF2[7:0] XOFF_WORD2 bit field.

21.3.8.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character completes. Detection of XOFF also sets the UARTi.UART_IIR[4] bit (if enabled by UARTi.UART_IER[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, the UARTi.UART_IIR[4] bit is cleared and the XOFF interrupt disappears.

NOTE: When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UARTi.UART_EFR[1:0] = 0x2, if XON1 and XOFF1 characters are received, they are not written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UARTi.UART_EFR[1:0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

21.3.8.1.3.3.2 Transmit (TX)

Two XOFF1 characters are transmitted when the RX FIFO passes the trigger level programmed by UARTi.UART_TCR[3:0]. As soon as the RX FIFO reaches the trigger level programmed by UARTi.UART_TCR[7:4], two XON1 characters are sent, so the data transfer recovers.

NOTE: If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

21.3.8.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an "at" (AT) command (ASCII code). These characteristics are used to receive data after an AT and to send data.

The following AT commands are valid:

AT	DATA	<CR>
at	DATA	<CR>
A/		
a/		

A line break during the acquisition of the sequence AT is not recognized, and an echo function is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to the RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved in the RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UARTi.UART_UASR register reflects the correct settings for the baud rate detected. Interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed:
  - 115.2K baud
  - 57.6K baud
  - 38.4K baud
  - 28.8K baud
  - 19.2K baud
  - 14.4K baud
  - 9.6K baud
  - 4.8K baud
  - 2.4K baud
  - 1.2K baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

NOTE: The combination of 7-bit character plus space parity is not supported.

Autobauding mode is selected when the UARTi.UART_MDR1[2:0] MODE_SELECT bit field is set to 0x2. In UART autobauding mode, UARTi.UART_DLL, UARTi.UART_DLH, and UARTi.UART_LCR[5:0] bit field settings are not used; instead, UART_UASR is updated with the configuration detected by the autobauding logic.

UART_UASR Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UARTi.UART_LCR, UARTi.UART_DLL, and UARTi.UART_DLH registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UARTi.UART_MDR1[2:0] MODE_ SELECT bit field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1200 and 115,200 bps (10 possibilities)

21.3.8.1.3.5 Error Detection

When the UARTi.UART_LSR register is read, the UARTi.UART_LSR[4:2] bit field reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (the next character to be read). Therefore, reading the UARTi.UART_LSR register and then reading the UARTi.UART_RHR register identifies errors in a character.

Reading the UARTi.UART_RHR register updates the BI, FE, and PE bits (see Table 21-11 for the UART mode interrupts).

The UARTi.UART_LSR[7] RX_FIFO_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

NOTE: Reading the UARTi.UART_LSR register does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the UARTi.UART_RHR register.

Reading the UARTi.UART_LSR register clears the OE bit if it is set (see Table 21-11 for the UART mode interrupts).

21.3.8.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the MPU with the UARTi.UART_IIR[5:1] IT_TYPE bit field set to 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the MPU must:

- Reset the RX FIFO.
- Read the UARTi.UART_RESUME register, which clears the internal flag.

21.3.8.1.3.7 Time-Out and Break Conditions

21.3.8.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (uarti_rx) is high for a time that equals 4x the programmed word length + 12 bits. uarti_rx is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on uarti_rx.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on uarti_rx or when the UARTi.UART_RHR register is read.

21.3.8.1.3.7.2 Break Condition

When a break condition occurs, uarti_tx is pulled low. A break condition is activated by setting the UARTi.UART_LCR[6] BREAK_EN bit. The break condition is not aligned on word stream (a break condition can occur in the middle of a character). The only way to send a break condition on a full character is:

1. Reset the TX FIFO (if enabled).
2. Wait for the transmit shift register to empty (the UARTi.UART_LSR[6] TX_SR_E bit is set to 1).

3. Take a guard time according to stop-bit definition.
4. Set the BREAK_EN bit to 1.

The break condition is asserted while the BREAK_EN bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

21.3.8.2 IrDA Mode

21.3.8.2.1 Slow Infrared (SIR) Mode

In SIR mode, data transfers take place between the LH and peripheral devices at speeds of up to 115200 bauds. A SIR transmit frame starts with start flags (either a single 0xC0, multiple 0xC0, or a single 0xC0 preceded by a number of 0xFF flags), followed by frame data, CRC-16, and ends with a stop flag (0xC1). The bit format for a single word uses a single start bit, eight data bits, and one stop bit. The format is unaffected by the use and settings of the LCR register.

Note that BLR[6] is used to select whether to use 0xC0 or 0xFF start patterns when multiple start flags are required.

The SIR transmit state machine attaches start flags, CRC-16, and stop flags. It checks the outgoing data to establish if data transparency is required.

SIR transparency is carried out if the outgoing data, between the start and stop flags, contains 0xC0, 0xC1, or 0x7D. If one of these is about to be transmitted, then the SIR state machine sends an escape character (0x7D) first, then inverts the fifth bit of the real data to be sent and sends this data immediately after the 0x7D character.

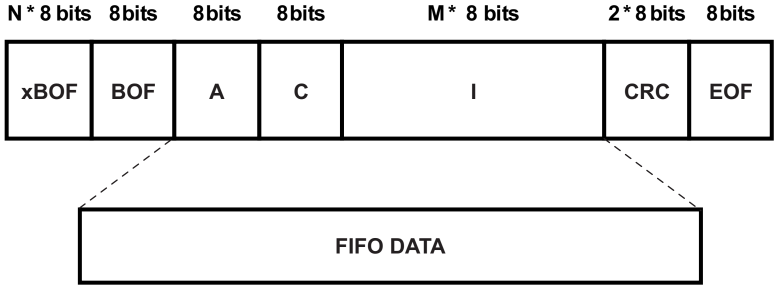
The SIR receive state machine recovers the receive clock, removes the start flags, removes any transparency from the incoming data, and determines frame boundary with reception of the stop flag. It also checks for errors, such as frame abort (0x7D character followed immediately by a 0xC1 stop flag, without transparency), CRC error, and frame-length error. At the end of a frame reception, the LH reads the line status register (LSR) to find out possible errors of the received frame.

Data can be transferred both ways by the module, but when the device is transmitting the IR RX circuitry is automatically disabled by hardware. See bit 5 in the auxiliary control register (ACREG) for a description of the logical operation. **Note:** This applies to all three modes SIR, MIR, and FIR.

The infrared output in SIR mode can either be 1.6µs or 3/16 encoding, selected by the PULSETYPE bit of the Auxiliary Control Register (ACREG[7]). In 1.6µs encoding, the infrared pulse width is 1.6µs and in 3/16 encoding the infrared pulse width is 3/16 of a bit duration (1/baud-rate). The receiver supports both 3/16 and 1.6µs pulse duration by default. The transmitting device must send at least two start flags at the start of each frame for back-to-back frames. **Note:** Reception supports variable-length stop bits.

21.3.8.2.1.1 Frame Format

Figure 21-16. IrDA SIR Frame Format



The CRC is applied on the address (A), control (C) and information (I) bytes.

Note: The two words of CRC are written in the FIFO in reception.

21.3.8.2.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to 0xC0 (BOF), 0xC1 (EOF), or 0x7D (control escape) it does the following.

In transmission

1. Inserts a control escape (CE) byte preceding the byte.
2. Complements bit 5 of the byte (i.e., exclusive OR's the byte with 0x20).

The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with 0x20).

In reception

For the A, C, I, CRC field:

1. Compare the byte with CE byte, and if not equal send it to the CRC detector and store it in the RX FIFO.
2. If equal to CE, discard the CE byte.
3. Complements the bit 5 of the byte following the CE.
4. 4. Send the complemented byte to the CRC detector and store it in the RX FIFO.

21.3.8.2.1.3 Abort Sequence

The transmitter may decide to prematurely close a frame. The transmitter aborts by sending the following sequence: 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

It is possible to abort a transmission frame by programming the ABORTEN bit of the Auxiliary Control Register (ACREG[1]). When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags. The receiver treats a frame as an aborted frame when a 0x7D character, followed immediately by a 0xC1 character, has been received without transparency.

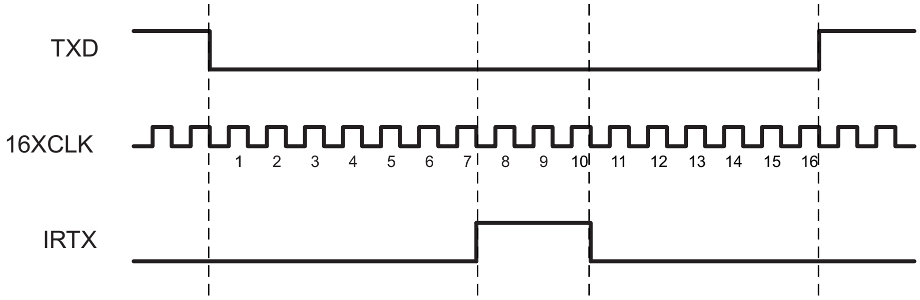
21.3.8.2.1.4 Pulse Shaping

In SIR mode, both the 3/16th and the 1.6μs pulse duration methods are supported in receive and transmit. ACREG[7] selects the pulse width method in transmit mode.

21.3.8.2.1.5 Encoder

Serial data from the transmit state machine is encoded to transmit data to the optoelectronics. While the serial data input to the (TXD) is high, the output (IRTX) is always low, and the counter used to form a pulse on IRTX is continuously cleared. After TXD resets to 0, IRTX rises on the falling edge of the 7th 16XCLK. On the falling edge of the 10th 16XCLK pulse, IRTX falls, creating a 3-clock-wide pulse. While TXD stays low, a pulse is transmitted during the 7th to the 10th clock of each 16-clock bit cycle.

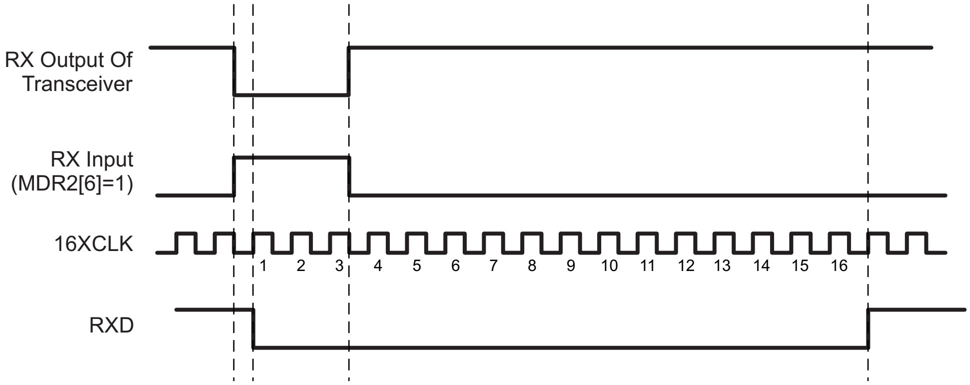
Figure 21-17. IrDA Encoding Mechanism



21.3.8.2.1.6 Decoder

After reset, RXD is high and the 4-bit counter is cleared. When a rising edge is detected on RX, RXD falls on the next rising edge of 16XCLK with sufficient setup time. RXD stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, RXD remains high.

Figure 21-18. IrDA Decoding Mechanism



The operation of the RX input can be disabled with DISIRRX bit of the Auxiliary Control Register (ACREG[5]). Furthermore, the MDR2[6] can be used to invert the signal from the transceiver (RX ouput) pin to the IRRX logic inside the UART.

21.3.8.2.1.7 IR Address Checking

In all IR modes, if address checking has been enabled, only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multi-point infrared environment. It is possible to program two frame addresses that the UART IrDA receives with XON1/ADDR1 and XON2/ADDR2 registers. Selecting address1 checking is done by setting EFR[0] to 1; address2 checking is done by setting EFR[1] to 1.

Setting EFR[1:0] to 0 disables all address checking operations. If both bits are set, then the incoming frame is checked for both private and public addresses. If address checking is disabled, then all received frames are written into the reception FIFO.

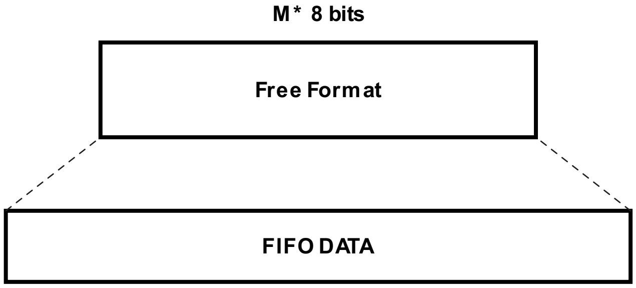
21.3.8.2.1.8 SIR Free Format Mode

To allow complete software flexibility in the transmission and reception of Infrared data packets, the SIR free format mode is a sub-function of the existing SIR mode such that all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values. In the transmission phase, the mode uses the IRTX pin, as in SIR mode.

This mode corresponds to a UART mode with a pulse modulation of 3/16 of baud-rate pulse width.

For example, a normal SIR packet has BOF control and CRC error checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs. In SIR free format mode, only the data termed the FIFO DATA area, illustrated in Figure 21-19, would be transmitted and received.

Figure 21-19. SIR Free Format Mode



In this mode, the entire FIFO data packet is to be constructed (encoded and decoded) by the LH software.

The SIR free format mode is selected by setting the module in UART mode (MDR1[2:0] = 000) and the MDR2[3] register bit to one to allow the pulse shaping. As the bit format is to remain the same, some UART mode configuration registers need to be set at specific value:

- LCR[1:0] = “11” (8 data bits)
- LCR[2] = 0 (1 stop bit)
- LCR[3] = 0 (no parity)
- ACREG[7] = 0 (3/16 of baud-rate pulse width)

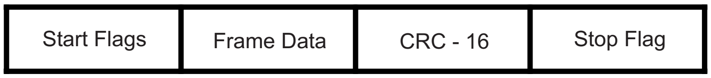
The features defined through MDR2[6] and ACREG[5] are also supported.

Note: - All other configuration registers need to be at the reset value. The UART mode interrupts are used for the SIR free format mode, but many of them are not relevant (e.g., XOFF, RTS, CTS, Modem status register).

21.3.8.2.2 Medium Infrared (MIR) Mode

In MIR mode, data transfers take place between LH and peripheral devices at 0.576 or 1.152 Mbits/s speed. A MIR transmit frame starts with start flags (at least two), followed by a frame data, CRC-16, and ends with a stop flag.

Figure 21-20. MIR Transmit Frame Format



On transmit, the MIR state machine attaches start flags, CRC-16, and stop flags. It also looks for five consecutive values of 1 in the frame data and automatically inserts a zero after five consecutive values of one (this is called bit stuffing).

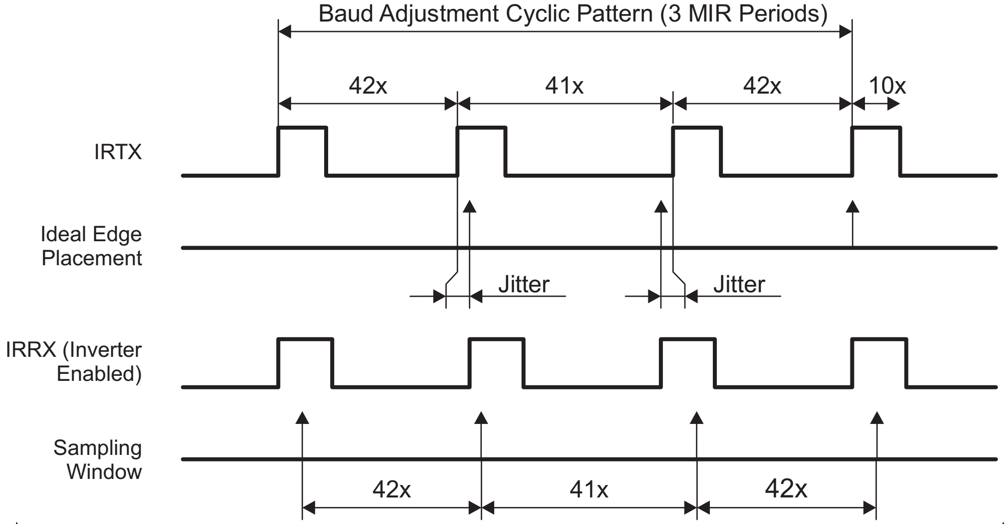
On receive, the MIR receive state machine recovers the receive clock, removes the start flags, de-stuffs the incoming data, and determines frame boundary with reception of the stop flag. It also checks for errors, such as frame abort, CRC error, or frame-length error. At the end of a frame reception, the LH reads the line status register (LSR) to find possible errors of received frame.

Data can be transferred both ways by the module but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See bit 5 in the auxiliary control register (ACREG) for a description of the logical operation. **Note:** This applies to all three modes SIR, MIR and FIR.

21.3.8.2.2.1 MIR Encoder/Decoder

In order to meet MIR baud-rate tolerance of +/-0.1% with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected. The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4 but within tolerances defined by the IrDA specifications.

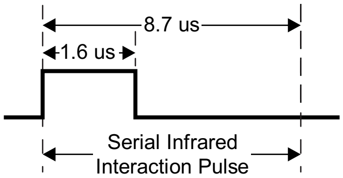
Figure 21-21. MIR BAUD Rate Adjustment Mechanism



21.3.8.2.2.2 SIP Generation

In MIR and FIR operation modes, the transmitter needs to send a serial infrared interaction pulse (SIP) at least once every 500 ms. The purpose of the SIP is to let slow devices (operating in SIR mode) know that the medium is currently occupied. The SIP pulse is shown in Figure 21-22

Figure 21-22. SIP Pulse



When the SIPMODE bit of Mode Definition Register 1 (MDR1[6]) equals 1, the TX state machine will always send one SIP at the end of a transmission frame. But when MDR1[6] = 0, the transmission of the SIP depends on the SENDSIP bit of the Auxiliary Control Register (ACREG[3]). The system (LH) can set ACREG[3] at least once every 500ms. The advantage of this approach over the default approach is that the TX state machine does not need to send the SIP at the end of each frame which may reduce the overhead required

21.3.8.2.3 Fast Infrared (FIR) Mode

In FIR mode, data transfers take place between LH and peripheral devices at 4 Mbits/s speed. A FIR transmit frame starts with a preamble, followed by a start flag, frame data, CRC-32, and ends with a stop flag.

Figure 21-23. FIR Transmit Frame Format

On transmit, the FIR transmit state machine attaches the preamble, start flag, CRC-32, and stop flag. It also encodes the transmit data into 4PPM format. It also generates the serial infrared interaction pulse (SIP).

On receive, the FIR receive state machine recovers the receive clock, removes the start flag, decodes the 4PPM incoming data, and determines frame boundary with a reception of the stop flag. It also checks for errors such as an illegal symbol, a CRC error, and a frame-length error. At the end of a frame reception, the LH reads the line status register (LSR) to find out possible errors of the received frame.

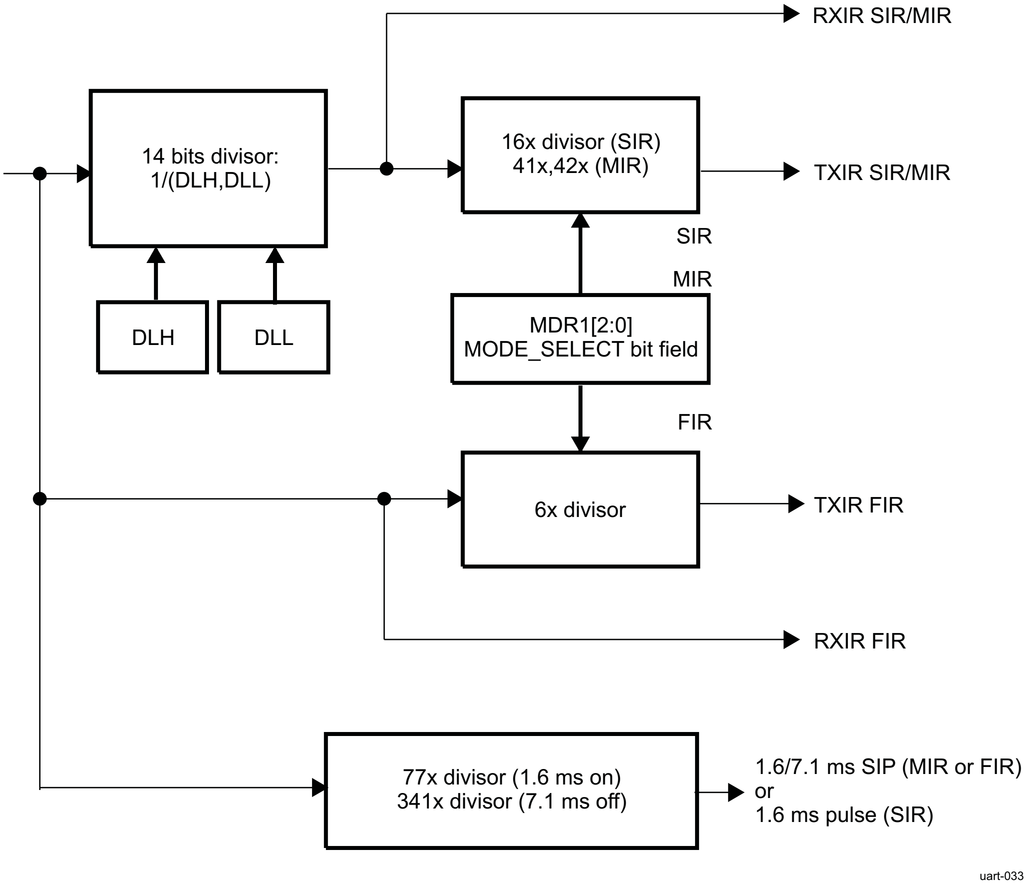
Data can be transferred both ways by the module but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See bit 5 in the auxiliary control register (ACREG) for a description of the logical operation. **Note:** This applies to all three modes of SIR, MIR, and FIR.

21.3.8.2.4 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 21-24 shows the baud rate generator and associated controls.

Figure 21-24. Baud Rate Generator



CAUTION

Before initializing or modifying clock parameter controls (UARTi.UART_DLH, UARTi.UART_DLL), MODE_SELECT=DISABLE (UARTi.UART_MDR1[2:0]) must be set to 0x7). Failure to observe this rule can result in unpredictable module behavior.

21.3.8.2.5 Choosing the Appropriate Divisor Value

Three divisor values are:

- SIR mode: Divisor value = Operating frequency/(16x baud rate)
- MIR mode: Divisor value = Operating frequency/(41x/42x baud rate)
- FIR mode: Divisor value = None

Table 21-28 lists the IrDA baud rate settings.

Table 21-28. IrDA Baud Rate Settings

Baud Rate	IR Mode	Baud Multiple	Encoding	DLH, DLL (Decimal)	Actual Baud Rate	Error (%)	Source Jitter (%)	Pulse Duration
2.4 kbps	SIR	16x	3/16	1250	2.4 kbps	0	0	78.1 µs
9.6 kbps	SIR	16x	3/16	312	9.6153 kbps	+0.16	0	19.5 µs
19.2 kbps	SIR	16x	3/16	156	19.231 kbps	+0.16	0	9.75 µs
38.4 kbps	SIR	16x	3/16	78	38.462 kbps	+0.16	0	4.87 µs
57.6 kbps	SIR	16x	3/16	52	57.692 kbps	+0.16	0	3.25 µs
115.2 kbps	SIR	16x	3/16	26	115.38 kbps	+0.16	0	1.62 µs
0.576 Mbps	MIR	41x/42x	1/4	2	0.5756 Mbps(1)	0	+1.63/–0.80	416 ns
1.152 Mbps	MIR	41x/42x	1/4	1	1.1511 Mbps(1)	0	+1.63/–0.80	208 ns
4 Mbps	FIR	6x	4 PPM	–	4 Mbps	0	0	125 ns

(1) Average value

NOTE: Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

21.3.8.2.6 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

21.3.8.2.6.1 IR RX Polarity Control

The UARTi.UART_MDR2[6] IRRXINVERT bit provides the flexibility to invert the uarti_rx_irrx pin in the UART to ensure that the protocol at the output of the transceiver has the same polarity at module level. By default, the uarti_rx_irrx pin is inverted because most transceivers invert the IR receive pin.

21.3.8.2.6.2 IrDA Reception Control

The module can transmit and receive data, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the uarti_rx_irrx input can be disabled by the UARTi.UART_ACREG[5] DIS_IR_RX bit.

21.3.8.2.6.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives, with the UARTi.UART_XON1_ADDR1[7:0] XON_WORD1 and UARTi.UART_XON2_ADDR2[7:0] XON_WORD2 bit fields.

Setting the UART_EFR[0] bit to 1 selects address1 checking. Setting the UART_EFR[1] bit to 1 selects address2 checking. Setting the UART_EFR[1:0] bit field to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for private and public addresses.

If address checking is disabled, all received frames write to the RX FIFO.

21.3.8.2.6.4 Frame Closing

A transmission frame can be terminated in two ways:

- Frame-length method: Set the UARTi.UART_MDR1[7] FRAME_END_MODE bit to 0. The MPU writes the value of the frame length to the UARTi.UART_TXFLH and UARTi.UART_TXFLL registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the value of the frame length.
- Set-EOT bit method: Set the FRAME_END_MODE bit to 1. The MPU writes 1 to the UARTi.UART_ACREG[0] EOT bit just before it writes the last byte to the TX FIFO. When the MPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

21.3.8.2.6.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the MPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or an entire frame (a small frame; that is, a supervisory frame), the MPU writes 1 to the UARTi.UART_ACREG[2] SCTX_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UARTi.UART_MDR1[5] SCT bit to 1. This transmission method differs from normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

21.3.8.2.6.6 Error Detection

When the UARTi.UART_LSR register is read, the UARTi.UART_LSR[4:2] bit field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (for IrDA mode interrupts, see Table 21-12). The STATUS FIFO must be read until empty (a maximum of eight reads is required).

21.3.8.2.6.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the MPU must:

- Reset the TX FIFO.
- Read the UARTi.UART_RESUME register, which clears the internal flag.

This function can be disabled by the UARTi.UART_ACREG[4] DIS_TX_UNDERRUN bit, compensated by the extension of the stop-bit in transmission if the TX FIFO is empty.

21.3.8.2.6.8 Overrun During Receive

Overrun during receive for the IrDA mode has the same function as that for the UART mode (see Section 21.3.8.1.3.6, *Overrun During Receive*).

21.3.8.2.6.9 Status FIFO

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading the UARTi.UART_SFREGH[3:0] MSB and UARTi.UART_SFREGL[3:0] (LSB) bit fields obtains the frame length. The frame error status is read in the UARTi.UART_SFLSR register. Reading the UARTi.UART_SFLSR register increments the status FIFO read pointer. Because the status FIFO is eight entries deep, it can hold the status of eight frames.

The MPU uses the frame-length information to locate the frame boundary in the received frame data. The MPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the MPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

21.3.8.2.7 SIR Mode Data Formatting

This section provides specific instructions for SIR mode programming.

21.3.8.2.7.1 Abort Sequence

The transmitter can prematurely close a frame (abort) by sending the sequence 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UARTi.UART_ACREG[1] ABORT_EN bit to 1. When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

When a 0x7D character followed immediately by a 0xC1 character is received without transparency, the receiver treats a frame as an aborted frame.

CAUTION

When the TX FIFO is not empty and the UARTi.UART_MDR1[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the aborted frame is sent. Therefore, the TX FIFO must be reset before sending an aborted frame.

21.3.8.2.7.2 Pulse Shaping

SIR mode supports the 3/16 or the 1.6-µs pulse duration methods in receive and transmit. The UARTi.UART_ACREG[7] PULSE_TYPE bit selects the pulse width method in the transmit mode.

21.3.8.2.7.3 SIR Free Format Programming

The SIR FF mode is selected by setting the module in the UART mode (UARTi.UART_MDR1[2:0] MODE_SELECT = 0x0) and the UARTi.UART_MDR2[3] UART_PULSE bit to 1 to allow pulse shaping.

Because the bit format stays the same, some UART mode configuration registers must be set at specific values:

- UARTi.UART_LCR[1:0] CHAR_LENGTH bit field = 0x3 (8 data bits)
- UARTi.UART_LCR[2] NB_STOP bit = 0x0 (1 stop-bit)
- UARTi.UART_LCR[3] PARITY_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many are not relevant (XOFF, RTS, CTS, modem status register, etc.).

21.3.8.2.8 MIR and FIR Mode Data Formatting

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the MPU reads the line status register (UARTi.UART_LSR) to detect errors in the received frame.

When the UARTi.UART_MDR1[6] SIP_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP_MODE bit is set to 0, SIP transmission depends on the UARTi.UART_ACREG[3] SEND_SIP bit.

The MPU can set the SEND_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, thus reducing the overhead required.

21.3.8.3 CIR Mode

In consumer infrared mode, the infrared operation is designed to function as a programmable (universal) remote control. By setting the MDR1 register, the UART can be set to CIR mode in the same way as the other IrDA modes are set using the MDR1 register.

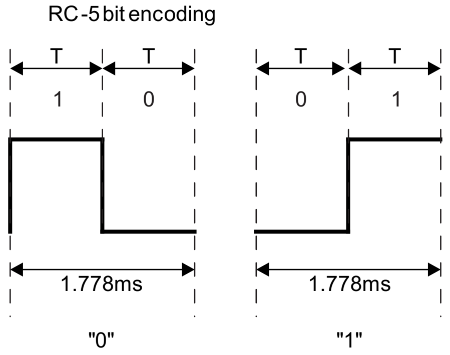
The CIR mode uses a variable pulse width modulation technique (based on multiples of a programmable T period) to encompass the various formats of infrared encoding for remote control applications. The CIR logic is to transmit and receive data packets according to the user definable frame structure and packet content.

21.3.8.3.1 Consumer IR Encoding

There are two distinct methods of encoding for remote control applications. The first uses time extended bit forms i.e. a variable pulse distance (or duration) whereby the difference between a logic one and logic zero is the length of the pulse width; and the second is the use of a bi-phase where the encoding of the logic zero and one is in the change of signal level from 1→0 or 0→1 respectively. Japanese manufacturers tend to favor the use of pulse duration encoding whereas European manufacturers favor the use of bi-phase encoding.

The CIR mode is designed to use a completely flexible free format encoding where a digit ‘1’ from the TX/RX FIFO is to be transmitted/received as a modulated pulse with duration T. Equally, a ‘0’ is to be transmitted/received as a blank duration T. The protocol of the data is to be constructed and deciphered by the host CPU. For example, the RC-5 protocol using Manchester encoding can be emulated as using a “01” pair for one and “10” pair for a zero.

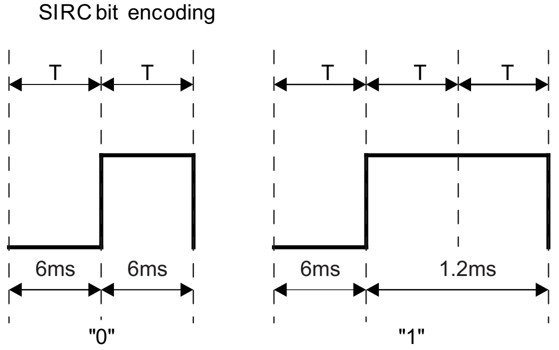
Figure 21-25. RC-5 Bit Encoding



Since the CIR mode logic does not impose a fixed format for infrared packets of data, the CPU software is at liberty to define the format through the use of simple data structures that will then be modulated into an industry standard, such as RC5 or SIRC. To send a sequence of “0101” in RC5, the host software must write an eight bit binary character of “10011001” to the data TX FIFO of the UART.

For SIRC, the modulation length (i.e. multiples of T) is the method to distinguish between a “1” or a “0”. The following SIRC digits show the difference in encoding between this and RC5 for example. Note: the pulse width is extended for “1” digits.

Figure 21-26. SIRC Bit Encoding



To construct comprehensive packets that constitute remote control commands, the host software must combine a number of eight bit data characters in a sequence that follows one of the universally accepted formats. For illustrative purposes, a standard RC5 frame is described below (the SIRC format follows this). Each of the above fields in RC-5 can be considered as two T pulses (digital bits) from the TX and RX FIFOs.

The standard RC5 format as seen by the UART_IrDA in CIR mode.

Figure 21-27. RC-5 Standard Packet Format

S1	S2	T	A4	A3	A2	A1	A0	C5	C4	C3	C2	C1	C0

Where:

- S1, S2: Start bits (always 1)
- T: Toggle bit
- A4–A0: Address (or system) bits
- C5–C0: Command bits

The toggle bit T changes each time a new command is transmitted to allow detection of pressing the same key twice (or effectively receiving the same data from the host consecutively). Since a code is being sent as long as the CPU transmits characters to the UART for transmission, a brief delay in the transmission of the same command would be detected by the use of the toggle bit. The address bits define the machine or device that the Infrared transmission is intended for and the command defines the operation.

To accommodate an extended RC5 format, the S2 bit is replaced by a further command bit (C6) that allows the command range to increase to 7-bits. This format is known as the extended RC-5 format.

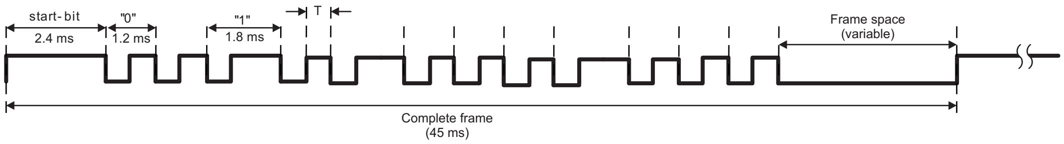
The SIRC encoding uses the duration of modulation for mark and space; hence the duration of data bits inside the standard frame length will vary depending upon the logic 1 content. The packet format and bit encoding is illustrated below. There is one start bit of two milliseconds and control codes followed by data that constitute the whole frame.

Figure 21-28. SIRC Packet Format

S	C0	C1	C2	C3	C4	C5	C6	D0	D1	D2	D3	D4

It should be noted that the encoding must take a standard duration but the contents of the data may vary. This implies that the control software for emitting and receiving data packets must exercise a scheme of inter-packet delay, where the emission of successive packets can only be done after a real time delay has expired.

Figure 21-29. SIRC Bit Transmission Example

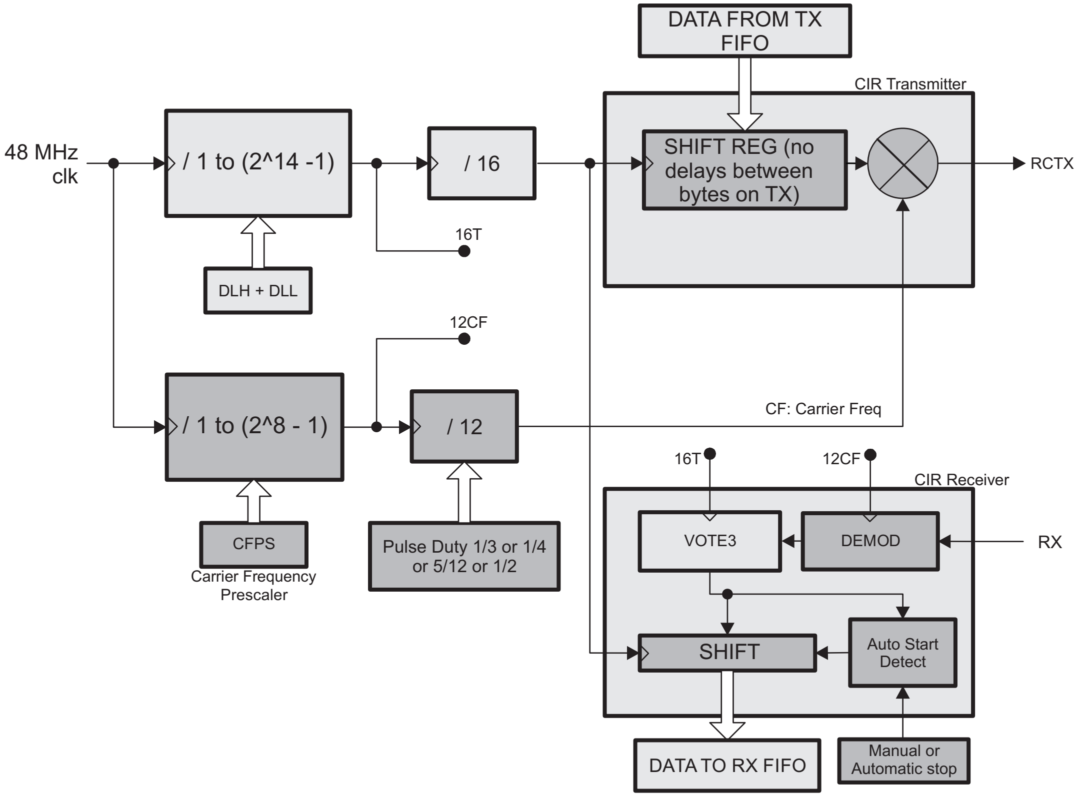


It is beyond the scope of this document to describe all encoding methods and techniques, the previous information was provided to illustrate the consideration required to employ different encoding methods for different industry standard protocols. The user should refer to industry standard documentation for specific methods of encoding and protocol usage.

21.3.8.3.2 CIR Mode Operation

Depending on the encoding method (variable pulse distance / bi-phase), the LH should develop a data structure that combines the 1 and 0 with a T period in order to encode the complete frame to transmit. This can then be transmitted to the infrared output with a method of modulation shown in the following diagram.

Figure 21-30. CIR Mode Block Components



In transmission, the LH software must exercise an element of real time control for transmitting data packets; they must each be emitted at a constant delay from the start bits of each of the individual packets which means when sending a series of packets, the packet to packet delay must respect a specific delay. To control this delay 2 methods can be used:

- By filling the TX FIFO with a number of zero bit which is transmitted with a T period.
- By using an external system timer which controls the delay either between each start of frame or between the end of a frame and the start of the next one. This can be performed:
  - By controlling the start of the frame through the configuration register MDR1[5] and ACREG[2] depending on the timer status (in case of control the delay between each start of frame).
  - By using the TX_STATUS interrupt IIR[5] to pre-load the next frame in the TX FIFO and to control the start of the timer (in case of control the delay between end of frame and start of next frame).

In reception, there are two ways to stop it :

- The LH can disable the reception by setting the ACREG[5] to 1 when it considers that the reception is finished because a large number of 0 has been received. To receive a new frame, the ACREG[5] must be set to 0.
- A specific mechanism, depending on the value set in the BOF length register (EBLR), allows for automatically stopping the reception. If the value set in the EBLR register is different than 0, this features is enabled and count a number of bit received at 0. When the counter achieves the value defined in the EBLR register, the reception is automatically stopped and RX_STOP_IT (IIR[2]) is set. When a 1 is detected on the RCRX pin, the reception is automatically enabled.

Note: There's a limitation when receiving data in UART CIR mode. The IrDA transceivers on the market have a common characteristic that shrinks the hold time of the received modulation pulse. The UART filtering schema on receiving is based on the same encoding mechanism used in transmission.

For the following scenario:

- Shift register period: 0.9 us
- Modulation frequency: 36 Khz
- Duty cycle: 1/4 of a modulation frequency period

The data sent in these conditions would look like 7us pulses within 28us period. The UART expects to receive similar incoming data on receive, but available transceiver timing characteristics typically send 2us modulated pulses. Those will be filtered out and RX FIFO won’t receive any data.

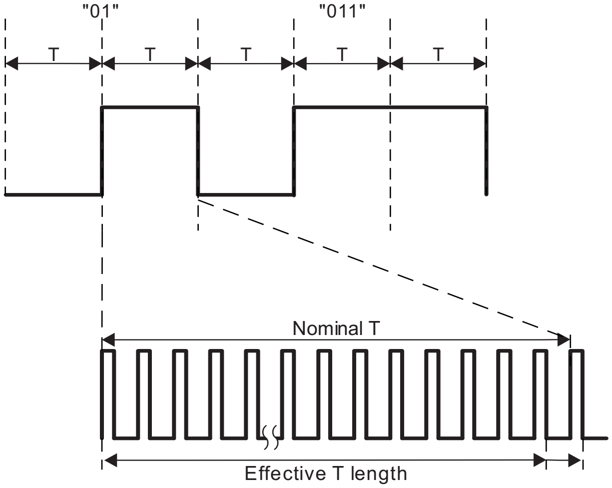
This does not affect UART CIR mode in transmission.

Note: The CIR RX demodulation can be bypassed by setting the MDR3[0] register bit.

21.3.8.3.3 Carrier Modulation

Looking closer at the actual modulation pulses of the infrared data stream, it should be noted that each modulated pulse that constitutes a digit is in fact a train of on/off pulses.

Figure 21-31. CIR Pulse Modulation



A minimum of 4 modulation pulses per bit is required by the module.

Based on the requested modulation frequency, the CFPS register must be set with the correct dividing value to provide the more accurate pulse frequency:

Dividing value = (FCLK/12)/MODfreq

Where FCLK = System clock frequency (48 MHz)

12 = real value of BAUD multiple

MODfreq = Effective frequency of the modulation (MHz)

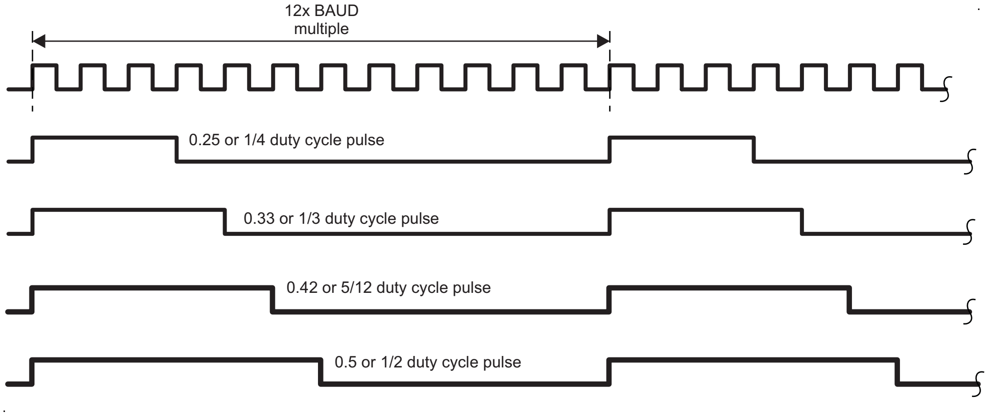
Example: For a targeted modulation frequency of 36 kHz, the CFPS value must be set to 111 in decimal which provide an modulation frequency of 36.04 kHz.

Note: The CFPS register is to start with a reset value of 105 (decimal) which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user defined by the pulse duty register bits in the MDR2 configuration register.

MDR2[5:4]	Duty Cycle (High Level)
00	1/4
01	1/3
10	5/12
11	1/2

Figure 21-32. CIR Modulation Duty Cycle



The transmission logic ensures that all pulses are transmitted completely; i.e., there is no cut off of any pulses during its transmission. Furthermore, while transmitting continuous bytes back-to-back, no delay is inserted between two transmitted bytes. **Note:** The CIR RX demodulation can be bypassed by setting the MDR3[0] register bit. This bit will not affect the transmission modulation.

21.3.8.3.4 Frequency Divider Values

The data transferred is a succession of pulse with a T period. Depending on the standards used, the T period is defined through the DLL and DLH registers which defined the value to divide the functional clock (48 MHz):

Dividing value = (FCLK/16)/Tfreq

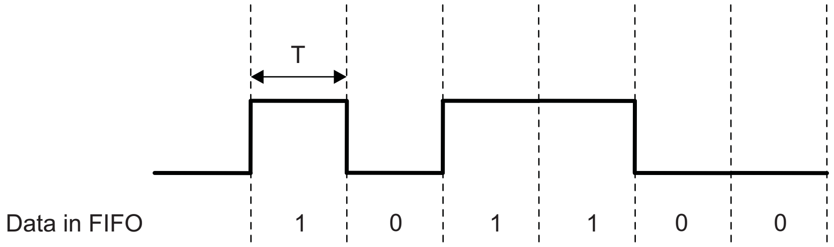
Where FCLK = System clock frequency (48 MHz)

16 = real value of BAUD multiple

Tfreq = Effective frequency of the T pulse (MHz)

In an example case using a variable pulse duration definitions:

Figure 21-33. Variable Pulse Duration Definitions



For a logical “1”, the pulse duration is equal to 2T and for a logical “0”, it’s equal to 4T.

If T =0.56 ms, the value coded into the DLH and DLL register must be 1680 in decimal.

21.4 UART/IrDA/CIR Basic Programming Model

21.4.1 UART Programming Model

21.4.1.1 Quick Start

This section describes the procedure for operating the UART with FIFO and DMA or interrupts. This three-part procedure ensures the quick start of the UART. It does not cover every UART feature.

The first programming model covers software reset of the UART. The second programming model describes FIFO and DMA configuration. The last programming model describes protocol, baud rate, and interrupt configuration.

NOTE: Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see Section 21.3.7.1, *Register Access Modes*.

21.4.1.1.1 Software Reset

To clear the UART registers, perform the following steps:

1. Initiate a software reset:

   Set the UARTi.UART_SYSC[1] SOFTRESET bit to 1.
2. Wait for the end of the reset operation:

   Poll the UARTi.UART_SYSS[0] RESETDONE bit until it equals 1.

21.4.1.1.2 FIFOs and DMA Settings

To enable and configure the receive and transmit FIFOs and program the DMA mode, perform the following steps:

1. Switch to register configuration mode B to access the UARTi.UART_EFR register:
   a. Save the current UARTi.UART_LCR register value.
   b. Set the UARTi.UART_LCR register value to 0x00BF.
2. Enable register submode TCR_TLR to access the UARTi.UART_TLR register (part 1 of 2):
   a. Save the UARTi.UART_EFR[4] ENHANCED_EN value.
   b. Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
3. Switch to register configuration mode A to access the UARTi.UART_MCR register:

   Set the UARTi.UART_LCR register value to 0x0080.
4. Enable register submode TCR_TLR to access the UARTi.UART_TLR register (part 2 of 2):
   a. Save the UARTi.UART_MCR[6] TCR_TLR value.
   b. Set the UARTi.UART_MCR[6] TCR_TLR bit to 1.
5. Enable the FIFO; load the new FIFO triggers (part 1 of 3) and the new DMA mode (part 1 of 2):

   Set the following bits to the desired values:
   - UARTi.UART_FCR[7:6] RX_FIFO_TRIG
   - UARTi.UART_FCR[5:4] TX_FIFO_TRIG
   - UARTi.UART_FCR[3] DMA_MODE
   - UARTi.UART_FCR[0] FIFO_ENABLE (0: Disable the FIFO; 1: Enable the FIFO)

NOTE: The UARTi.UART_FCR register is not readable.

6. Switch to register configuration mode B to access the UARTi.UART_EFR register:
   Set the UARTi.UART_LCR register value to 0x00BF.
7. Load the new FIFO triggers (part 2 of 3):
   Set the following bits to the desired values:
   - UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA
   - UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA
8. Load the new FIFO triggers (part 3 of 3) and the new DMA mode (part 2 of 2):
   Set the following bits to the desired values:
   - UARTi.UART_SCR[7] RX_TRIG_GRANU1
   - UARTi.UART_SCR[6] TX_TRIG_GRANU1
   - UARTi.UART_SCR[2:1] DMA_MODE_2
   - UARTi.UART_SCR[0] DMA_MODE_CTL
9. Restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 2a.
10. Switch to register configuration mode A to access the UARTi.UART_MCR register:
    Set the UARTi.UART_LCR register value to 0x0080.
11. Restore the UARTi.UART_MCR[6] TCR_TLR value saved in Step 4a.
12. Restore the UARTi.UART_LCR value saved in Step 1a.

Triggers are used to generate interrupt and DMA requests. See Section 21.3.6.1.1, *Transmit FIFO Trigger,* to choose the following values:

- UARTi.UART_FCR[5:4] TX_FIFO_TRIG
- UARTi.UART_TLR[3:0] TX_FIFO_TRIG_DMA
- UARTi.UART_SCR[6] TX_TRIG_GRANU1

Triggers are used to generate interrupt and DMA requests. See Section 21.3.6.1.2, *Receive FIFO Trigger*, to choose the following values:

- UARTi.UART_FCR[7:6] RX_FIFO_TRIG
- UARTi.UART_TLR[7:4] RX_FIFO_TRIG_DMA
- UARTi.UART_SCR[7] RX_TRIG_GRANU1

DMA mode enables DMA requests. See Section 21.3.6.4, *FIFO DMA Mode Operation*, to choose the following values:

- UARTi.UART_FCR[3] DMA_MODE
- UARTi.UART_SCR[2:1] DMA_MODE_2
- UARTi.UART_SCR[0] DMA_MODE_CTL

21.4.1.1.3 Protocol, Baud Rate, and Interrupt Settings

To program the protocol, baud rate, and interrupt settings, perform the following steps:

1. Disable UART to access the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Switch to register configuration mode B to access the UARTi.UART_EFR register:
   Set the UARTi.UART_LCR register value to 0x00BF.
3. Enable access to the UARTi.UART_IER[7:4] bit field:
   a. Save the UARTi.UART_EFR[4] ENHANCED_EN value.
   b. Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
4. Switch to register operational mode to access the UARTi.UART_IER register:
   Set the UARTi.UART_LCR register value to 0x0000.

5. Clear the UARTi.UART_IER register (set the UARTi.UART_IER[4] SLEEP_MODE bit to 0 to change the UARTi.UART_DLL and UARTi.UART_DLH registers). Set the UARTi.UART_IER register value to 0x0000.
6. Switch to register configuration mode B to access the UARTi.UART_DLL and UARTi.UART_DLH registers:

   Set the UARTi.UART_LCR register value to 0x00BF.
7. Load the new divisor value:

   Set the UARTi.UART_DLL[7:0] CLOCK_LSB and UARTi.UART_DLH[5:0] CLOCK_MSB bit fields to the desired values.
8. Switch to register operational mode to access the UARTi.UART_IER register:

   Set the UARTi.UART_LCR register value to 0x0000.
9. Load the new interrupt configuration (0: Disable the interrupt; 1: Enable the interrupt):

   Set the following bits to the desired values:
   - UARTi.UART_IER[7] CTS_IT
   - UARTi.UART_IER[6] RTS_IT
   - UARTi.UART_IER[5] XOFF_IT
   - UARTi.UART_IER[4] SLEEP_MODE
   - UARTi.UART_IER[3] MODEM_STS_IT
   - UARTi.UART_IER[2] LINE_STS_IT
   - UARTi.UART_IER[1] THR_IT
   - UARTi.UART_IER[0] RHR_IT
10. Switch to register configuration mode B to access the UARTi.UART_EFR register:

    Set the UARTi.UART_LCR register value to 0x00BF.
11. Restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 3a.
12. Load the new protocol formatting (parity, stop-bit, character length) and switch to register operational mode:

    Set the UARTi.UART_LCR[7] DIV_EN bit to 0.

    Set the UARTi.UART_LCR[6] BREAK_EN bit to 0.

    Set the following bits to the desired values:
    - UARTi.UART_LCR[5] PARITY_TYPE_2
    - UARTi.UART_LCR[4] PARITY_TYPE_1
    - UARTi.UART_LCR[3] PARITY_EN
    - UARTi.UART_LCR[2] NB_STOP
    - UARTi.UART_LCR[1:0] CHAR_LENGTH
13. Load the new UART mode:

    Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to the desired value.

See Section 21.3.8.1.2, *Choosing the Appropriate Divisor Value*, to choose the following values:

- UARTi.UART_DLL[7:0] CLOCK_LSB
- UARTi.UART_DLH[5:0] CLOCK_MSB
- UARTi.UART_MDR1[2:0] MODE_SELECT

See Section 21.3.8.1.3.1, *Frame Formatting*, to choose the following values:

- UARTi.UART_LCR[5] PARITY_TYPE_2
- UARTi.UART_LCR[4] PARITY_TYPE_1
- UARTi.UART_LCR[3] PARITY_EN
- UARTi.UART_LCR[2] NB_STOP
- UARTi.UART_LCR[1:0] CHAR_LENGTH

21.4.1.2 Hardware and Software Flow Control Configuration

This section describes the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

NOTE: Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see Section 21.3.7.1, *Register Access Modes*.

21.4.1.2.1 Hardware Flow Control Configuration

To enable and configure hardware flow control, perform the following steps:

1. Switch to register configuration mode A to access the UARTi.UART_MCR register:
   a. Save the current UARTi.UART_LCR register value.
   b. Set the UARTi.UART_LCR register value to 0x0080.
2. Enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 1 of 2):
   a. Save the UARTi.UART_MCR[6] TCR_TLR value.
   b. Set the UARTi.UART_MCR[6] TCR_TLR bit to 1.
3. Switch to register configuration mode B to access the UARTi.UART_EFR register:

   Set the UARTi.UART_LCR register value to 0x00BF.
4. Enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 2 of 2):
   a. Save the UARTi.UART_EFR[4] ENHANCED_EN value.
   b. Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
5. Load the new start and halt trigger values for hardware flow control:

   Set the following bits to the desired values:
   - UARTi.UART_TCR[7:4] AUTO_RTS_START
   - UARTi.UART_TCR[3:0] AUTO_RTS_HALT
6. Enable or disable receive and transmit hardware flow control mode and restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 4a.

   Set the following bits to the desired values:
   - UARTi.UART_EFR[7] AUTO_CTS_EN (0: Disable; 1: Enable)
   - UARTi.UART_EFR[6] AUTO_RTS_EN (0: Disable; 1: Enable)

   Restore the UARTi.UART_EFR[4] ENHANCED_EN bit to the saved value.
7. Switch to register configuration mode A to access the UARTi.UART_MCR register:

   Set the UARTi.UART_LCR register value to 0x0080.
8. Restore the UARTi.UART_MCR[6] TCR_TLR value saved in Step 2a.
9. Restore the UARTi.UART_LCR value saved in Step 1a.

See Section 21.3.8.1.3.2, *Hardware Flow Control*, to choose the following values:

- UARTi.UART_EFR[7] AUTO_CTS_EN
- UARTi.UART_EFR[6] AUTO_RTS_EN
- UARTi.UART_TCR[7:4] AUTO_RTS_START
- UARTi.UART_TCR[3:0] AUTO_RTS_HALT

21.4.1.2.2 Software Flow Control Configuration

To enable and configure software flow control, perform the following steps:

1. Switch to register configuration mode B to access the UARTi.UART_EFR register.
    a. Save the current UARTi.UART_LCR register value.
    b. Set the UARTi.UART_LCR register value to 0x00BF.
2. Enable register submode XOFF to access the UARTi.UART_XOFF1 and UARTi.UART_XOFF2 registers:
    a. Save the UARTi.UART_EFR[4] ENHANCED_EN value.
    b. Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 0.
3. Load the new software flow control characters:

    Set the following bits to the desired values:
    - UARTi.UART_XON1_ADDR1[7:0] XON_WORD1
    - UARTi.UART_XON2_ADDR2[7:0] XON_WORD2
    - UARTi.UART_XOFF1[7:0] XOFF_WORD1
    - UARTi.UART_XOFF2[7:0] XOFF_WORD2
4. Enable access to the UARTi.UART_MCR[7:5] bit field and enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 1 of 2):

    Set the UARTi.UART_EFR[4] ENHANCED_EN bit to 1.
5. Switch to register configuration mode A to access the UARTi.UART_MCR register:

    Set the UARTi.UART_LCR register value to 0x0080.
6. Enable register submode TCR_TLR to access the UARTi.UART_TCR register (part 2 of 2) and enable or disable XON any function:
    a. Save the UARTi.UART_MCR[6] TCR_TLR value.
    b. Set the UARTi.UART_MCR[6] TCR_TLR bit to 1.
    c. Set the UARTi.UART_MCR[5] XON_EN bit to the desired value (0: Disable; 1: Enable).
7. Switch to register configuration mode B to access the UARTi.UART_EFR register:

    Set the UARTi.UART_LCR register value to 0x00BF.
8. Load the new start and halt trigger values for software flow control:

    Set the following bits to the desired values:
    - UARTi.UART_TCR[7:4] AUTO_RTS_START
    - UARTi.UART_TCR[3:0] AUTO_RTS_HALT
9. Enable or disable special character function and load the new software flow control mode and restore the UARTi.UART_EFR[4] ENHANCED_EN value saved in Step 2a:

    Set the following bits to the desired values:
    - UARTi.UART_EFR[5] SPEC_CHAR (0: Disable; 1: Enable)
    - UARTi.UART_EFR[3:0] SW_FLOW_CONTROL

    Restore the UARTi.UART_EFR[4] ENHANCED_EN bit to the saved value.
10. Switch to register configuration mode A to access the UARTi.UART_MCR register:

    Set the UARTi.UART_LCR register value to 0x0080.
11. Restore the UARTi.UART_MCR[6] TCR_TLR bit value saved in Step 6a.
12. Restore the UARTi.UART_LCR value saved in Step 1a.

See Section 21.3.8.1.3.3, *Software Flow Control*, to choose the following values:

- UARTi.UART_EFR[5] SPEC_CHAR
- UARTi.UART_EFR[3:0] SW_FLOW_CONTROL
- UARTi.UART_TCR[7:4] AUTO_RTS_START
- UARTi.UART_TCR[3:0] AUTO_RTS_HALT

- UARTi.UART_XON1_ADDR1[7:0] XON_WORD1
- UARTi.UART_XON2_ADDR2[7:0] XON_WORD2
- UARTi.UART_XOFF1[7:0] XOFF_WORD1
- UARTi.UART_XOFF2[7:0] XOFF_WORD2

21.4.2 IrDA Programming Model

21.4.2.1 SIR Mode

21.4.2.1.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with parity forced to 1, baud rate = 112.5KB, FIFOs disabled, 2 stop-bits, and 8-bit word length:

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers: Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (the UART_LCR[7] DIV_EN bit = 1): UARTi.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UARTi.UART_LCR register in IrDA mode.)
3. Load the new baud rate (115.2 kbps):

   UARTi.UART_DLL = 0x1A
   UARTi.UART_DLH = 0x00
4. Set SIR mode: UARTi.UART_MDR1[2:0] MODE_SELECT = 0x1
5. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode: UARTi.UART_LCR = 0x00.
6. Optional: Enable the RHR interrupt:

   UARTi.UART_IER[0] RHR_IT = 0x1

21.4.2.1.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 6-byte frame with no parity, baud rate = 112.5 kbps, FIFOs disabled, 3/16 encoding, 2 stop-bits, and 7-bit word length:

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers: Set the UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_EFR register:

   UARTi.UART_LCR = 0xBF
3. Enable the enhanced features (the UART_EFR[4] ENAHNCED_EN bit = 1):

   Set the UARTi.UART_EFR register value to 0x10.
4. Grant access to the UART_DLL and UART_DLH registers (the UART_LCR[7] DIV_EN bit = 1):

   UARTi.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UARTi.UART_LCR register in IrDA mode.)
5. Load the new baud rate (115.2 kbps):

   UARTi.UART_DLL = 0x1A
   UARTi.UART_DLH = 0x00
6. Set SIR mode (the UART_MDR1[2:0] MODE_SELECT bit field = 0x1): UARTi.UART_MDR1 = 0x01
7. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode: UARTi.UART_LCR = 0x00.
8. Force DTR output to active:

   UARTi.UART_MCR[0] DTR = 1
9. Optional: Enable the THR interrupt:

   UARTi.UART_IER[1] THR_IT = 1
10. Set transmit frame length to 6 bytes:

    UARTi.UART_TXFLL = 0x06
11. Set 7 starts of frame transmission:

    UARTi.UART_EBLR = 0x08

12. Optional: Set SIR pulse width to be 1.6 us:
    UARTi.UART_ACREG[7] PULSE_TYPE = 1
13. Load the UART_THR register with the data to be transmitted.

21.4.2.2 MIR Mode

21.4.2.2.1 Receive

The following programming model explains how to program the module to receive an IrDA frame with no parity, baud rate = 1.152 Mpbs, and FIFOs disabled.

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (UART_LCR[7] DIV_EN bit = 1):
   UARTi.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UARTi.UART_LCR register in IrDA mode.)
3. Load the new baud rate (1.152 Mpbs):
   UARTi.UART_DLL = 0x01
   UARTi.UART_DLH = 0x00
4. Set MIR mode:
   UARTi.UART_MDR1[2:0] MODE_SELECT = 0x4
5. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
   UARTi.UART_LCR = 0x00
6. Force DTR output to active (UART_MCR[0] DTR = 1):
   Force RTS output to active (UART_MCR[1] RTS = 1).
   UARTi.UART_MCR = 0x3
7. Optional: Enable the RHR interrupt:
   UARTi.UART_IER[0] RHR_IT = 1

21.4.2.2.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 60-byte frame with no parity, baud rate = 1.152 Mpbs, and FIFOs disabled:

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers:
   Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (UART_LCR[7] DIV_EN bit = 1):
   UARTi.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UARTi.UART_LCR register in IrDA mode.)
3. Load the new baud rate (1.152 Mpbs):
   UARTi.UART_DLL = 0x01
   UARTi.UART_DLH = 0x00
4. Set MIR mode:
   UARTi.UART_MDR1[2:0] MODE_SELECT = 0x4
5. Disable access to the UART_DLL and UART_DLH registers and switch to register operational mode:
   UARTi.UART_LCR = 0x00
6. Force DTR output to active:
   UARTi.UART_MCR[0] DTR = 1
7. Optional: Enable the THR interrupt:
   UARTi.UART_IER[1] THR_IT = 1
8. Set the frame length to 60 bytes:
   UARTi.UART_TXFLL = 0x3C
9. Optional: Transmit eight additional starts of frame (MIR mode requires two starts):

UARTi.UART_EBLR = 0x08

10. SIP is sent at the end of transmission:

    UARTi.UART_ACREG[3] = 1

11. Load the UART_THR register with the data to be transmitted.

21.4.2.3 FIR Mode

21.4.2.3.1 Receive

The following programming model explains how to program the module to receive the IrDA frame with no parity, baud rate = 4 Mbps, FIFOs enabled, 8-bit word length.

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers: Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to the UART_DLL and UART_DLH registers (UART_LCR[7] DIV_EN bit = 1):

   UARTi.UART_LCR = 0x80 (Data format is unaffected by the use and settings of the UARTi.UART_LCR register in IrDA mode.)
3. FIFO clear and enable:

   UARTi.UART_FCR = 0x7 (TX/RX FIFO trigger: UART_FCR[7:6] and UART_FCR[5:4])
   UARTi.UART_LCR[7] = 0
4. Set FIR mode:
   UARTi.UART_MDR1[2:0] MODE_SELECT = 0x5
5. Set frame length:

   UARTi.UART_RXFLL = 0xA (Data + CRC + STOP)
6. Disable access to the UARTi.UART_DLL registers and UARTi.UART_DLH and switch to register operational mode:

   UARTi.UART_LCR[7] DIV_EN = 0x0
7. Optional: Enable the RHR interrupt:

   UARTi.UART_IER[0] RHR_IT = 1

21.4.2.3.2 Transmit

The following programming model explains how to program the module to transmit an IrDA 4-byte frame with no parity, baud rate = 4 Mbps, FIFOs enabled, and 8-bit word length.

1. Disable the UART before accessing the UARTi.UART_DLL and UARTi.UART_DLH registers: Set the UARTi.UART_MDR1[2:0] MODE_SELECT bit field to 0x7.
2. Grant access to EFR_REG:

   UARTi.UART_LCR = 0xBF
3. Enable the enhanced features (EFR_REG[4] ENAHNCED_EN = 0x1):

   UARTi.UART_EFR = 0x10
4. FIFO clear and enable:
   UARTi.UART_FCR = 0x7 (TX/RX FIFO trigger: UART_FCR[7:6] and UART_FCR[5:4]).

   UARTi.UART_LCR[7] = 0
5. Set FIR mode and enable auto-SIP mode:

   UARTi.UART_MDR1 = 0x45
6. Set frame length:

   UARTi.UART_TXFLL = 0x4
   UARTi.UART_TXFLH = 0x0
   UARTi.UART_RXFLL = 0xA (Data + CRC + STOP)
   UARTi.UART_RXFLH = 0x0
7. Force DTR output to active:

   UARTi.UART_MCR[0] DTR = 0x1

8. Optional: Enable the THR interrupt:
   UARTi.UART_IER[1] THR_IT = 0x1
9. Optional: Transmit eight additional starts of frame (MIR mode requires two starts):
   UARTi.UART_EBLR = 0x08
10. SIP is sent at the end of transmission:
    UARTi.UART_ACREG[3] = 1
11. Load the UART_THR register with the data to be transmitted.

21.5 UART Registers

21.5.1 UART Registers

Table 21-29 lists the memory-mapped registers for the UART. All register offset addresses not listed in Table 21-29 should be considered as reserved locations and the register contents should not be modified.

21.5.1.1 UART_THR Register (offset = 0h) [reset = 0h]

UART_THR is shown in Figure 21-34 and described in Table 21-30.

The transmit holding register (THR) is selected with the register bit setting of LCR[7] = 0. The transmitter section consists of the transmit holding register and the transmit shift register. The transmit holding register is a 64-byte FIFO. The MPU writes data to the THR. The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location zero of the FIFO is used to store the data.

21.5.1.2 UART_RHR Register (offset = 0h) [reset = 0h]

UART_RHR is shown in Figure 21-35 and described in Table 21-31.

The receiver holding register (RHR) is selected with the register bit setting of LCR[7] = 0. The receiver section consists of the receiver holding register and the receiver shift register. The RHR is actually a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR. If the FIFO is disabled, location zero of the FIFO is used to store the single data character. If an overflow occurs, the data in the RHR is not overwritten.

21.5.1.3 UART_DLL Register (offset = 0h) [reset = 0h]

UART_DLL is shown in Figure 21-36 and described in Table 21-32.

The divisor latches low register (DLL) is selected with a register bit setting of LCR[7] not equal to BFh or LCR[7] = BFh. The divisor latches low register (DLL) with the DLH register stores the 14-bit divisor for generation of the baud clock in the baud rate generator. DLH stores the most-significant part of the divisor, DLL stores the least-significant part of the divisor. DLL and DLH can be written to only before sleep mode is enabled (before IER[4] is set).

21.5.1.4 UART_IER_IRDA Register (offset = 4h) [reset = 0h]

UART_IER_IRDA is shown in Figure 21-37 and described in Table 21-33.

The following interrupt enable register (IER) description is for IrDA mode. The IrDA IER is selected with a register bit setting of LCR[7] = 0. In IrDA mode, EFR[4] has no impact on the access to IER[7:4]. The IrDA interrupt enable register (IER) can be programmed to enable/disable any interrupt. There are 8 types of interrupt in these modes, received EOF, LSR interrupt, TX status, status FIFO interrupt, RX overrun, last byte in RX FIFO, THR interrupt, and RHR interrupt. Each interrupt can be enabled/disabled individually. The TXSTATUSIT interrupt reflects two possible conditions. The MDR2[0] bit should be read to determine the status in the event of this interrupt.

21.5.1.5 UART_IER_CIR Register (offset = 4h) [reset = 0h]

UART_IER_CIR is shown in Figure 21-38 and described in Table 21-34.

The following interrupt enable register (IER) description is for CIR mode. The CIR IER is selected with a register bit setting of LCR[7] = 0. In IrDA mode, EFR[4] has no impact on the access to IER[7:4]. The CIR interrupt enable register (IER) can be programmed to enable/disable any interrupt. There are 5 types of interrupt in these modes, TX status, RX overrun, RX stop interrupt, THR interrupt, and RHR interrupt. Each interrupt can be enabled/disabled individually. In CIR mode, the TXSTATUSIT bit has only one meaning corresponding to the case MDR2[0] = 0. The RXSTOPIT interrupt is generated based on the value set in the BOF Length register (EBLR).

21.5.1.6 UART_IER Register (offset = 4h) [reset = 0h]

UART_IER is shown in Figure 21-39 and described in Table 21-35.

The following interrupt enable register (IER) description is for UART mode. The UART IER is selected with a register bit setting of LCR[7] = 0. In UART mode, IER[7:4] can only be written when EFR[4] = 1 The interrupt enable register (IER) can be programmed to enable/disable any interrupt. There are seven types of interrupt in this mode: receiver error, RHR interrupt, THR interrupt, XOFF received and CTS (active-low)/RTS (active-low) change of state from low to high. Each interrupt can be enabled/disabled individually. There is also a sleep mode enable bit. The UART interrupt enable register (IER) is shown in and described in .

21.5.1.7 UART_DLH Register (offset = 4h) [reset = 0h]

UART_DLH is shown in Figure 21-40 and described in Table 21-36.

The divisor latches high register (DLH) is selected with a register bit setting of LCR[7] not equal to BFh or LCR[7] = BFh. The divisor latches high register (DLH) with the DLL register stores the 14-bit divisor for generation of the baud clock in the baud rate generator. DLH stores the most-significant part of the divisor, DLL stores the least-significant part of the divisor. DLL and DLH can be written to only before sleep mode is enabled (before IER[4] is set).

21.5.1.8 UART_EFR Register (offset = 8h) [reset = 0h]

UART_EFR is shown in Figure 21-41 and described in Table 21-37.

The enhanced feature register (EFR) is selected with a register bit setting of LCR[7] = BFh. The enhanced feature register (EFR) enables or disables enhanced features. Most enhanced functions apply only to UART modes, but EFR[4] enables write accesses to FCR[5:4], the TX trigger level, which is also used in IrDA modes.

Table 21-37. UART_EFR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	
7	AUTOCTSEN	R/W	0h	Auto-CTS enable bit (UART mode only). 0h (R/W) = Normal operation. 1h (R/W) = Auto-CTS flow control is enabled; transmission is halted when the CTS (active-low) pin is high (inactive).
6	AUTORTSEN	R/W	0h	Auto-RTS enable bit (UART mode only). 0h (R/W) = Normal operation. 1h (R/W) = Auto-RTS flow control is enabled; RTS (active-low) pin goes high (inactive) when the receiver FIFO HALT trigger level, TCR[3:0], is reached and goes low (active) when the receiver FIFO RESTORE transmission trigger level is reached.
5	SPECIALCHARDETECT	R/W	0h	Special character detect (UART mode only). 0h (R/W) = Normal operation. 1h (R/W) = Special character detect enable. Received data is compared with XOFF2 data. If a match occurs, the received data is transferred to RX FIFO and the IIR[4] bit is set to 1 to indicate that a special character was detected.
4	ENHANCEDEN	R/W	0h	Enhanced functions write enable bit. 0h (R/W) = Disables writing to IER[7:4], FCR[5:4], and MCR[7:5]. 1h (R/W) = Enables writing to IER[7:4], FCR[5:4], and MCR[7:5].

Table 21-37. UART_EFR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-0	SWFLOWCTRL	R/W	0h	Combinations of software flow control can be selected by programming this bit. XON1 and XON2 should be set to different values if the software flow control is enabled. The TX and RX software flow control options are as follows. EFR[3] = 0, EFR[2] = 0, EFR[1] = X, and EFR[0] = X, then: No transmit flow control. EFR[3] = 1, EFR[2] = 0, EFR[1] = X, and EFR[0] = X, then: Transmit XON1, XOFF1. EFR[3] = 0, EFR[2] = 1, EFR[1] = X, and EFR[0] = X, then: Transmit XON2, XOFF2. EFR[3] = 1, EFR[2] = 1, EFR[1] = X, and EFR[0] = X, then: Transmit XON1, XON2 or XOFF1, XOFF2. The XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2. EFR[3] = X, EFR[2] = X, EFR[1] = 0, and EFR[0] = 0, then: No receive flow control. EFR[3] = X, EFR[2] = X, EFR[1] = 1, and EFR[0] = 0, then: Receiver compares XON1, XOFF1. EFR[3] = X, EFR[2] = X, EFR[1] = 0, and EFR[0] = 1, then: Receiver compares XON2, XOFF2. EFR[3] = X, EFR[2] = X, EFR[1] = 1, and EFR[0] = 1, then: Receiver compares XON1, XON2 or XOFF1, XOFF2. The XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2. In IrDA mode, EFR[1] and EFR[0] select the IR address to check (see IR Address Checking).

21.5.1.9 UART_IIR Register (offset = 8h) [reset = 1h]

UART_IIR is shown in Figure 21-42 and described in Table 21-38.

The following interrupt identification register (IIR) description is for UART mode. The UART IIR is selected with a register bit setting of LCR[7] = 0 or LCR[7] not equal to BFh. The UART interrupt identification register (IIR) is a read-only register that provides the source of the interrupt. An interrupt source can be flagged only if enabled in the IER register.

21.5.1.10 UART_IIR_CIR Register (offset = 8h) [reset = 0h]

UART_IIR_CIR is shown in Figure 21-43 and described in Table 21-39.

The following interrupt identification register (IIR) description is for CIR mode. The CIR IIR is selected with a register bit setting of LCR[7] = 0 or LCR[7] not equal to BFh. The CIR interrupt identification register (IIR) is a read-only register that provides the source of the interrupt. An interrupt source can be flagged only if enabled in the IER register.

21.5.1.11 UART_FCR Register (offset = 8h) [reset = 0h]

UART_FCR is shown in Figure 21-44 and described in Table 21-40.

The FIFO control register (FCR) is selected with a register bit setting of LCR[7] = 0 or LCR[7] not equal to BFh. FCR[5:4] can only be written when EFR[4] = 1.

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	
7-6	RX_FIFO_TRIG	W	0h	Sets the trigger level for the RX FIFO: If SCR[7] = 0 and TLR[7] to TLR[4] not equal to 0000, RX_FIFO_TRIG is not considered. If SCR[7] = 1, RX_FIFO_TRIG is 2 LSB of the trigger level (1 to 63 on 6 bits) with the granularity 1. If SCR[7] = 0 and TLR[7] to TLR[4] = 0000, then: 0h (R/W) = 8 characters 1h (R/W) = 16 characters 2h (R/W) = 56 characters 3h (R/W) = 60 characters
5-4	TX_FIFO_TRIG	W	0h	Can be written only if EFR[4] = 1. Sets the trigger level for the TX FIFO: If SCR[6] = 0 and TLR[3] to TLR[0] not equal to 0000, TX_FIFO_TRIG is not considered. If SCR[6] = 1, TX_FIFO_TRIG is 2 LSB of the trigger level (1 to 63 on 6 bits) with a granularity of 1. If SCR[6] = 0 and TLR[3] to TLR[0] = 0000, then: 0h (R/W) = 8 characters 1h (R/W) = 16 characters 2h (R/W) = 32 characters 3h (R/W) = 56 characters
3	DMA_MODE	W	0h	Can be changed only when the baud clock is not running (DLL and DLH cleared to 0). If SCR[0] = 0, this register is considered. 0h (R/W) = DMA_MODE 0 (No DMA). 1h (R/W) = DMA_MODE 1 (UART_NDMA_REQ[0] in TX, UART_NDMA_REQ[1] in RX).
2	TX_FIFO_CLR	W	0h	TX_FIFO_CLEAR. 0h (R/W) = No change. 1h (R/W) = Clears the transmit FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO.
1	RX_FIFO_CLR	W	0h	RX_FIFO_CLEAR. 0h (R/W) = No change. 1h (R/W) = Clears the receive FIFO and resets its counter logic to 0. Returns to 0 after clearing FIFO.
0	FIFO_EN	W	0h	Can be changed only when the baud clock is not running (DLL and DLH cleared to 0). 0h (R/W) = Disables the transmit and receive FIFOs. The transmit and receive holding registers are 1-byte FIFOs. 1h (R/W) = Enables the transmit and receive FIFOs. The transmit and receive holding registers are 64-byte FIFOs.

21.5.1.12 UART_LCR Register (offset = Ch) [reset = 0h]

UART_LCR is shown in Figure 21-45 and described in Table 21-41.

The line control register (LCR) is selected with a bit register setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. As soon as LCR[6] is set to 1, the TX line is forced to 0 and remains in this state as long as LCR[6] = 1.

5	RX_LAST_BYTE	R	1h	RX_LAST_BYTE. 0h (R/W) = The RX FIFO (RHR) does not contain the last byte of the frame to be read. 1h (R/W) = The RX FIFO (RHR) contains the last byte of the frame to be read. This bit is set to 1 only when the last byte of a frame is available to be read. It is used to determine the frame boundary. It is cleared on a single read of the LSR register.
4	FRM_TOO_LONG	R	0h	FRAME_TOO_LONG. 0h (R/W) = No frame-too-long error in frame. 1h (R/W) = Frame-too-long error in the frame at the top of the status FIFO (next character to be read). This bit is set to 1 when a frame exceeding the maximum length (set by RXFLH and RXFLL registers) is received. When this error is detected, current frame reception is terminated. Reception is stopped until the next START flag is detected.
3	ABORT	R	0h	ABORT. 0h (R/W) = No abort pattern error in frame. 1h (R/W) = Abort pattern received. SIR and MIR - abort pattern. FIR - Illegal symbol.
2	CRC	R	0h	CRC. 0h (R/W) = No CRC error in frame. 1h (R/W) = CRC error in the frame at the top of the status FIFO (next character to be read).
1	STS_FIFO_E	R	1h	STS_FIFO_E. 0h (R/W) = Status FIFO is not empty. 1h (R/W) = Status FIFO is empty.
0	RX_FIFO_E	R	1h	RX_FIFO_E. 0h (R/W) = At least one data character in the RX FIFO. 1h (R/W) = No data in the receive FIFO.

21.5.1.18 UART_LSR Register (offset = 14h) [reset = 60h]

UART_LSR is shown in Figure 21-51 and described in Table 21-47.

The following line status register (LSR) description is for UART mode. The UART LSR is selected with a register bit setting of LCR[7] = 0 or LCR[7] not equal to BFh. When the UART line status register (LSR) is read, LSR[4:2] reflect the error bits (BI, FE, PE) of the character at the top of the RX FIFO (next character to be read). Therefore, reading the LSR and then reading the RHR identifies errors in a character. Reading RHR updates BI, FE, and PE. LSR [7] is set when there is an error anywhere in the RX FIFO and is cleared only when there are no more errors remaining in the RX FIFO. Reading the LSR does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading the RHR. Reading LSR clears OE if set.

21.5.1.19 UART_TCR Register (offset = 18h) [reset = 0h]

UART_TCR is shown in Figure 21-52 and described in Table 21-48.

The transmission control register (TCR) is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. The TCR is accessible only when EFR[4] = 1 and MCR[6] = 1. The transmission control register (TCR) stores the receive FIFO threshold levels to start/stop transmission during hardware flow control. Trigger levels from 0-60 bytes are available with a granularity of 4. Trigger level = 4 x [4-bit register value]. You must ensure that TCR[3:0] > TCR[7:4], whenever auto-RTS or software flow control is enabled to avoid a misoperation of the device. In FIFO interrupt mode with flow control, you have to also ensure that the trigger level to HALT transmission is greater or equal to receive FIFO trigger level (either TLR[7:4] or FCR[7:6]); otherwise, FIFO operation stalls. In FIFO DMA mode with flow control, this concept does not exist because the DMA request is sent each time a byte is received.

21.5.1.20 UART_MSR Register (offset = 18h) [reset = 0h]

UART_MSR is shown in Figure 21-53 and described in Table 21-49.

The modem status register (MSR) is selected with a register bit setting of LCR[7] = 0 or LCR[7] not equal to BFh. The modem status register (MSR) provides information about the current state of the control lines from the modem, data set, or peripheral device to the Local Host. It also indicates when a control input from the modem changes state.

21.5.1.23 UART_TLR Register (offset = 1Ch) [reset = 0h]

UART_TLR is shown in Figure 21-56 and described in Table 21-52.

The trigger level register is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. The TLR is accessible only when EFR[4] = 1 and MCR[6] = 1. This register stores the programmable transmit and receive FIFO trigger levels used for DMA and IRQ generation.

7-4	RX_FIFO_TRIG_DMA	R/W	0h	Receive FIFO trigger level. Following is a summary of settings for the RX FIFO trigger level. SCR[7] = 0, and TLR[7] to TLR[4]=0, then: Defined by FCR[7] and FCR[6] (either 8, 16, 56, 60 characters). SCR[7] = 0, and TLR[7] to TLR[4] not equal to 0000, then: Defined by TLR[7] to TLR[4] (from 4 to 60 characters with a granularity of 4 characters). SCR[7] = 1, and TLR[7] to TLR[4] = any value, then: Defined by the concatenated value of TLR[7] to TLR[4] and FCR[7] and FCR[6] (from 1 to 63 characters with a granularity of 1 character). Note: the combination of TLR[7] to TLR[4] = 0000 and FCR[7] and FCR[6] = 00 (all zeros) is not supported (minimum of 1 character is required). All zeros results in unpredictable behavior.
3-0	TX_FIFO_TRIG_DMA	R/W	0h	Transmit FIFO trigger level. Following is a summary of settings for the TX FIFO trigger level. SCR[6] = 0, and TLR[3] to TLR[0] = 0, then: Defined by FCR[5] and FCR[4] (either 8, 16, 32, 56 characters). SCR[6] = 0, and TLR[3] to TLR[0] not equal to 0000, then: Defined by TLR[3] to TLR[0] (from 4 to 60 characters with a granularity of 4 characters). SCR[6] = 1, and TLR[3] to TLR[0] = any value, then: Defined by the concatenated value of TLR[3] and TLR[0] and FCR[5] and FCR[4] (from 1 to 63 characters with a granularity of 1 character). Note: the combination of TLR[3] to TLR[0] = 0000 and FCR[5] and FCR[4] = 00 (all zeros) is not supported (minimum of 1 character is required). All zeros results in unpredictable behavior.

21.5.1.24 UART_XOFF2 Register (offset = 1Ch) [reset = 0h]

UART_XOFF2 is shown in Figure 21-57 and described in Table 21-53.

The XOFF2 register is selected with a register bit setting of LCR[7] = BFh. In UART mode, XOFF2 character.

21.5.1.25 UART_MDR1 Register (offset = 20h) [reset = 7h]

UART_MDR1 is shown in Figure 21-58 and described in Table 21-54.

The mode definition register 1 (MDR1) is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. The mode of operation is programmed by writing to MDR1[2:0]; therefore, the mode definition register 1 (MDR1) must be programmed on startup after configuration of the configuration registers (DLL, DLH, and LCR). The value of MDR1[2:0] must not be changed again during normal operation. If the module is disabled by setting the MODESELECT field to 7h, interrupt requests can still be generated unless disabled through the interrupt enable register (IER). In this case, UART mode interrupts are visible. Reading the interrupt identification register (IIR) shows the UART mode interrupt flags.

6	SIPMODE	R/W	0h	MIR/FIR modes only. 0h (R/W) = Manual SIP mode: SIP is generated with the control of ACREG[3]. 1h (R/W) = Automatic SIP mode: SIP is generated after each transmission.
5	SCT	R/W	0h	Store and control the transmission. 0h (R/W) = Starts the infrared transmission when a value is written to the THR register. 1h (R/W) = Starts the infrared transmission with the control of ACREG[2]. Note: Before starting any transmission, there must be no reception ongoing.
4	SETTXIR	R/W	0h	Used to configure the infrared transceiver. 0h (R/W) = If MDR2[7] = 0, no action; if MDR2[7] = 1, TXIR pin output is forced low. 1h (R/W) = TXIR pin output is forced high (not dependant of MDR2[7] value).
3	IRSLEEP	R/W	0h	IrDA/CIR sleep mode. 0h (R/W) = IrDA/CIR sleep mode disabled. 1h (R/W) = IrDA/CIR sleep mode enabled.
2-0	MODESELECT	R/W	7h	UART/IrDA/CIR mode selection. 0h (R/W) = UART 16x mode. 1h (R/W) = SIR mode. 2h (R/W) = UART 16x auto-baud. 3h (R/W) = UART 13x mode. 4h (R/W) = MIR mode. 5h (R/W) = FIR mode. 6h (R/W) = CIR mode. 7h (R/W) = Disable (default state).

21.5.1.26 UART_MDR2 Register (offset = 24h) [reset = 0h]

UART_MDR2 is shown in Figure 21-59 and described in Table 21-55.

The mode definition register 2 (MDR2) is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. The MDR2[0] bit describes the status of the TX status interrupt in IIR[5]. The IRTXUNDERRUN bit must be read after a TX status interrupt occurs. The MDR2[2:1] bits set the trigger level for the frame status FIFO (8 entries) and must be programmed before the mode is programmed in MDR1[2:0]. The MDR2[6] bit gives the flexibility to invert the RX pin inside the UART module to ensure that the protocol at the input of the transceiver module has the same polarity at module level. By default, the RX pin is inverted because most of transceiver invert the IR receive pin.

Table 21-55. UART_MDR2 Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	RESERVED	R	0h	
7	SETTXIRALT	R/W	0h	Provides alternate functionality for MDR1[4]. 0h (R/W) = Normal mode 1h (R/W) = Alternate mode for SETTXIR
6	IRRXINVERT	R/W	0h	Only for IR mode (IrDA and CIR). Invert RX pin in the module before the voting or sampling system logic of the infrared block. This does not affect the RX path in UART modem modes. 0h (R/W) = Inversion is performed. 1h (R/W) = No inversion is performed.
5-4	CIRPULSEMODE	R/W	0h	CIR pulse modulation definition. Defines high level of the pulse width associated with a digit: 0h (R/W) = Pulse width of 3 from 12 cycles. 1h (R/W) = Pulse width of 4 from 12 cycles. 2h (R/W) = Pulse width of 5 from 12 cycles. 3h (R/W) = Pulse width of 6 from 12 cycles.
3	UARTPULSE	R/W	0h	UART mode only. Used to allow pulse shaping in UART mode. 0h (R/W) = Normal UART mode. 1h (R/W) = UART mode with pulse shaping.
2-1	STSFIFOTRIG	R/W	0h	Only for IrDA mode. Frame status FIFO threshold select: 0h (R/W) = 1 entry 1h (R/W) = 4 entries 2h (R/W) = 7 entries 3h (R/W) = 8 entries
0	IRTXUNDERRUN	R	0h	IrDA transmission status interrupt. When the TX status interrupt (IIR[5]) occurs, the meaning of the interrupt is: 0h (R/W) = The last bit of the frame was transmitted successfully without error. 1h (R/W) = An underrun occurred. The last bit of the frame was transmitted but with an underrun error. The bit is reset to 0 when the RESUME register is read.

21.5.1.27 UART_TXFLL Register (offset = 28h) [reset = 0h]

UART_TXFLL is shown in Figure 21-60 and described in Table 21-56.

The transmit frame length low register (TXFLL) is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. The transmit frame length low register (TXFLL) and the TXFLH register hold the 13-bit transmit frame length (expressed in bytes). TXFLL holds the LSBs and TXFLH holds the MSBs. The frame length value is used if the frame length method of frame closing is used.

21.5.1.28 UART_SFLSR Register (offset = 28h) [reset = 0h]

UART_SFLSR is shown in Figure 21-61 and described in Table 21-57.

The status FIFO line status register (SFLSR) is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. Reading the status FIFO line status register (SFLSR) effectively reads frame status information from the status FIFO. This register does not physically exist. Reading this register increments the status FIFO read pointer (SFREGL and SFREGH must be read first). Top of RX FIFO = Next frame to be read from RX FIFO.

21.5.1.29 UART_RESUME Register (offset = 2Ch) [reset = 0h]

UART_RESUME is shown in Figure 21-62 and described in Table 21-58.

The RESUME register is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. The RESUME register is used to clear internal flags, which halt transmission/reception when an underrun/overrun error occurs. Reading this register resumes the halted operation. This register does not physically exist and always reads as 00.

21.5.1.31 UART_RXFLL Register (offset = 30h) [reset = 0h]

UART_RXFLL is shown in Figure 21-64 and described in Table 21-60.

The received frame length low register (RXFLL) is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. The received frame length low register (RXFLL) and the RXFLH register hold the 12-bit receive maximum frame length. RXFLL holds the LSBs and RXFLH holds the MSBs. If the intended maximum receive frame length is n bytes, program RXFLL and RXFLH to be n + 3 in SIR or MIR modes and n + 6 in FIR mode (+3 and +6 are the result of frame format with CRC and stop flag; two bytes are associated with the FIR stop flag).

21.5.1.32 UART_SFREGL Register (offset = 30h) [reset = 0h]

UART_SFREGL is shown in Figure 21-65 and described in Table 21-61.

The status FIFO register low (SFREGL) is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. The frame lengths of received frames are written into the status FIFO. This information can be read by reading the status FIFO register low (SFREGL) and the status FIFO register high (SFREGH). These registers do not physically exist. The LSBs are read from SFREGL and the MSBs are read from SFREGH. Reading these registers does not alter the status FIFO read pointer. These registers must be read before the pointer is incremented by reading the SFLSR.

21.5.1.35 UART_BLR Register (offset = 38h) [reset = 40h]

UART_BLR is shown in Figure 21-68 and described in Table 21-64.

The BOF control register (BLR) is selected with a register bit setting of LCR[7] = 0. The BLR[6] bit is used to select whether C0h or FFh start patterns are to be used, when multiple start flags are required in SIR mode. If only one start flag is required, this is always C0h. If n start flags are required, either (n - 1) C0h or (n -1) FFh flags are sent, followed by a single C0h flag (immediately preceding the first data byte).

21.5.1.36 UART_UASR Register (offset = 38h) [reset = 0h]

UART_UASR is shown in Figure 21-69 and described in Table 21-65.

The UART autobauding status register (UASR) is selected with a register bit setting of LCR[7] not equal to BFh or LCR[7] = BFh. The UART autobauding status register (UASR) returns the speed, the number of bits by characters, and the type of parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition. This register is used to set up transmission according to characteristics of previous reception, instead of LCR, DLL, and DLH registers when UART is in autobauding mode. To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), MDR1[2:0] must be set to 7h (reset state), then set to 2h (UART in autobaud mode) or cleared to 0 (UART in standard mode). Usage limitation: Only 7 and 8 bits character (5 and 6 bits not supported). 7 bits character with space parity not supported. Baud rate between 1200 and 115 200 bp/s (10 possibilities).

21.5.1.37 UART_ACREG Register (offset = 3Ch) [reset = 0h]

UART_ACREG is shown in Figure 21-70 and described in Table 21-66.

The auxiliary control register (ACREG) is selected with a register bit setting of LCR[7] = 0. If transmit FIFO is not empty and MDR1[5] = 1, IrDA starts a new transfer with data of previous frame as soon as abort frame has been sent. Therefore, TX FIFO must be reset before sending an abort frame. It is recommended to disable TX FIFO underrun capability by masking corresponding underrun interrupt. When disabling underrun by setting ACREG[4] = 1, unknown data is sent over TX line.

6	SDMOD	R/W	0h	Primary output used to configure transceivers. Connected to the SD/MODE input pin of IrDA transceivers. 0h (R/W) = SD pin is set to high. 1h (R/W) = SD pin is set to low.
5	DISIRRX	R/W	0h	Disable RX input. 0h (R/W) = Normal operation (RX input automatically disabled during transmit, but enabled outside of transmit operation). 1h (R/W) = Disables RX input (permanent state; independent of transmit).
4	DISTXUNDERRUN	R/W	0h	Disable TX underrun. 0h (R/W) = Long stop bits cannot be transmitted. TX underrun is enabled. 1h (R/W) = Long stop bits can be transmitted.
3	SENDSIP	R/W	0h	MIR/FIR modes only. Send serial infrared interaction pulse (SIP). If this bit is set during an MIR/FIR transmission, the SIP is sent at the end of it. This bit is automatically cleared at the end of the SIP transmission. 0h (R/W) = No action. 1h (R/W) = Send SIP pulse.
2	SCTXEN	R/W	0h	Store and control TX start. When MDR1[5] = 1 and the LH writes 1 to this bit, the TX state-machine starts frame transmission. This bit is self-clearing.
1	ABORTEN	R/W	0h	Frame abort. The LH can intentionally abort transmission of a frame by writing 1 to this bit. Neither the end flag nor the CRC bits are appended to the frame.
0	EOTEN	R/W	0h	EOT (end-of-transmission) bit. The LH writes 1 to this bit just before it writes the last byte to the TX FIFO in the set-EOT bit frame-closing method. This bit is automatically cleared when the LH writes to the THR (TX FIFO).

21.5.1.38 UART_SCR Register (offset = 40h) [reset = 0h]

UART_SCR is shown in Figure 21-71 and described in Table 21-67.

The supplementary control register (SCR) is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. Bit 4 enables the wake-up interrupt, but this interrupt is not mapped into the IIR register. Therefore, when an interrupt occurs and there is no interrupt pending in the IIR register, the SSR[1] bit must be checked. To clear the wake-up interrupt, bit SCR[4] must be reset to 0.

0	DMAMODECTL	R/W	0h	DMAMODECT 0h (R/W) = The DMAMODE is set with FCR[3]. 1h (R/W) = The DMAMODE is set with SCR[2:1].

21.5.1.39 UART_SSR Register (offset = 44h) [reset = 4h]

UART_SSR is shown in Figure 21-72 and described in Table 21-68.

The supplementary status register (SSR) is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. Bit 1 is reset only when SCR[4] is reset to 0.

1	RXCTSDSRWAKEUPSTS	R	0h	Pin falling edge detection: Reset only when SCR[4] is reset to 0. 0h (R/W) = No falling-edge event on RX, CTS (active-low), and DSR (active-low). 1h (R/W) = A falling edge occurred on RX, CTS (active-low), or DSR (active-low).
0	TXFIFOFULL	R	0h	TXFIFOFULL. 0h (R/W) = TX FIFO is not full. 1h (R/W) = TX FIFO is full.

21.5.1.40 UART_EBLR Register (offset = 48h) [reset = 0h]

UART_EBLR is shown in Figure 21-73 and described in Table 21-69.

The BOF length register (EBLR) is selected with a register bit setting of LCR[7] = 0. In IrDA SIR operation, the BOF length register (EBLR) specifies the number of BOF + xBOFs to transmit. The value set into this register must consider the BOF character; therefore, to send only one BOF with no XBOF, this register must be set to 1. To send one BOF with n XBOFs, this register must be set to n + 1. Furthermore, the value 0 sends 1 BOF plus 255 XBOFs. In IrDA MIR mode, the BOF length register (EBLR) specifies the number of additional start flags (MIR protocol mandates a minimum of 2 start flags). In CIR mode, the BOF length register (EBLR) specifies the number of consecutive zeros to be received before generating the RXSTOP interrupt (IIR[2]). All the received zeros are stored in the RX FIFO. When the register is cleared to 0, this feature is deactivated and always in reception state, which is disabled by setting the ACREG[5] bit to 1. If the RX_STOP interrupt occurs before a byte boundary, the remaining bits of the last byte are filled with zeros and then passed into the RX FIFO.

FFh (R/W) = Generate RXSTOP interrupt after receiving 255 zero bits.

21.5.1.41 UART_MVR Register (offset = 50h) [reset = 0h]

UART_MVR is shown in Figure 21-74 and described in Table 21-70.

The module version register (MVR) is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. The reset value is fixed by hardware and corresponds to the RTL revision of this module. A reset has no effect on the value returned.

21.5.1.42 UART_SYSC Register (offset = 54h) [reset = 0h]

UART_SYSC is shown in Figure 21-75 and described in Table 21-71.

The system configuration register (SYSC) is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. The AUTOIDLE bit controls a power-saving technique to reduce the logic power consumption of the module interface; that is, when the feature is enabled, the interface clock is gated off until the module interface is accessed. When the SOFTRESET bit is set high, it causes a full device reset.

21.5.1.44 UART_WER Register (offset = 5Ch) [reset = FFh]

UART_WER is shown in Figure 21-77 and described in Table 21-73.

The wake-up enable register (WER) is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. The wake-up enable register (WER) is used to mask and unmask a UART event that subsequently notifies the system. An event is any activity in the logic that can cause an interrupt and/or an activity that requires the system to wake up. Even if wakeup is disabled for certain events, if these events are also an interrupt to the UART, the UART still registers the interrupt as such.

21.5.1.45 UART_CFPS Register (offset = 60h) [reset = 69h]

UART_CFPS is shown in Figure 21-78 and described in Table 21-74.

The carrier frequency prescaler register (CFPS) is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. Since the consumer IR (CIR) works at modulation rates of 30-56.8 kHz, the 48 MHz clock must be prescaled before the clock can drive the IR logic. The carrier frequency prescaler register (CFPS) sets the divisor rate to give a range to accommodate the remote control requirements in BAUD multiples of 12x. The value of the CFPS at reset is 105 decimal (69h), which equates to a 38.1 kHz output from starting conditions. The 48 MHz carrier is prescaled by the CFPS that is then divided by the 12x BAUD multiple.

21.5.1.51 UART_MDR3 Register (offset = 80h) [reset = 0h]

UART_MDR3 is shown in Figure 21-84 and described in Table 21-80.

The mode definition register 3 (MDR3) is selected with a register bit setting of LCR[7] = 0, LCR[7] not equal to BFh, or LCR[7] = BFh. The DISABLE_CIR_RX_DEMOD register bit will force the CIR receiver to bypass demodulation of received data if set. See the CIR Mode Block Components. The NONDEFAULT_FREQ register bit allows the user to set sample per bit by writing it into FREQ_SEL register. Set it if non-default (48 MHz) fclk frequency is used to achieve a less than 2% error rate. Changing this bit (to any value) will automatically disable the device by setting MDR[2:0] to 111 .

I2C

This chapter describes the I2C of the device.

Topic **Page**

22.1 Introduction

The multi-master I2C peripheral provides an interface between a CPU and any I2C-bus-compatible device that connects via the I2C serial bus. External components attached to the I2C bus can serially transmit/receive up to 8-bit data to/from the CPU device through the two-wire I2C interface.

The I2C bus is a multi-master bus. The I2C controller does support the multi-master mode that allows more than one device capable of controlling the bus to be connected to it. Each I2C device is recognized by a unique address and can operate as either transmitter or receiver, according to the function of the device. In addition to being a transmitter or receiver, a device connected to the I2C bus can also be considered as master or slave when performing data transfers. Note that a master device is the device which initiates a data transfer on the bus and generates the clock signals to permit that transfer. During this transfer, any device addressed by this master is considered a slave.

22.1.1 I2C Features

The general features of the I2C controller are:

- Compliant with Philips I2C specification version 2.1
- Supports standard mode (up to 100K bits/s) and fast mode (up to 400K bits/s).
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit modes
- 7-bit and 10-bit device addressing modes
- Built-in 32-byte FIFO for buffered read or writes in each module
- Programmable clock generation
- Two DMA channels, one interrupt line

22.1.2 Unsupported I2C Features

The I2C module features not supported in this device are shown in Table 22-1.

Table 22-1. Unsupported I2C Features

Feature	Reason
SCCB Protocol	SCCB signal not pinned out
High Speed (3.4 MBPS) operation	Not supported

22.2 Integration

This device includes three instantiations of the I2C module. This peripheral implements the multi-master I2C bus which allows serial transfer of 8-bit data to/from other I2C master/slave devices through a two-wire interface. There are three I2C modules instantiations called I2C0, I2C1, and I2C2. The I2C0 module is located in the Wake-up power domain. Figure 22-1 and Figure 22-2 show examples of a system with multiple I2C-compatible devices.

Figure 22-1. I2C0 Integration and Bus Application

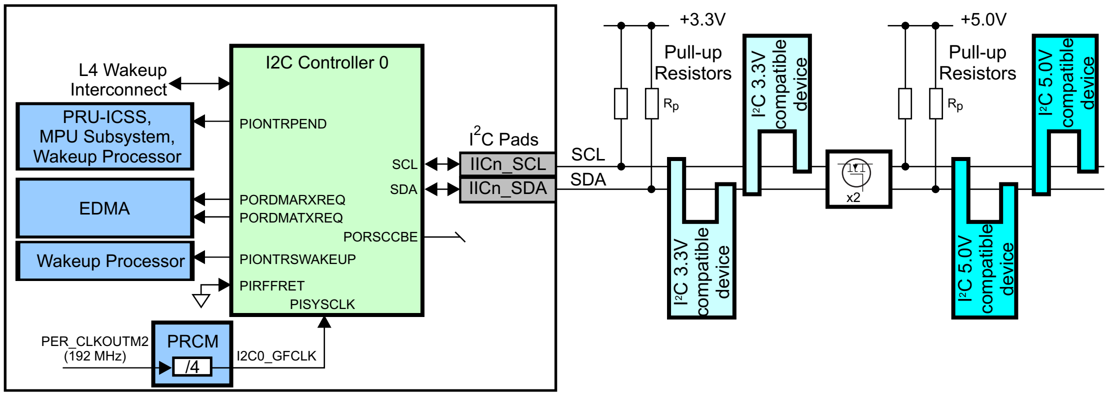

Figure 22-2. I2C(1–2) Integration and Bus Application

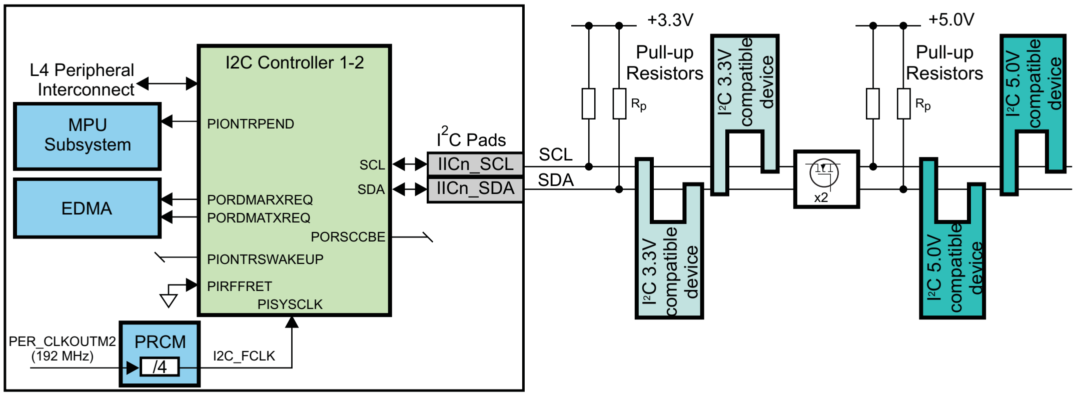


22.2.1 *I2C Connectivity Attributes*

The general connectivity attributes for the I2C module are shown in Table 22-2 and Table 22-3.

Table 22-2. I2C0 Connectivity Attributes

Attributes	Type
Power Domain	Wakeup Domain
Clock Domain	PD_WKUP_L4_WKUP_GCLK (Interface/OCP) PD_WKUP_I2C0_GFCLK (Func)
Reset Signals	WKUP_DOM_RST_N
Idle/Wakeup Signals	Smart Idle / Wakeup
Interrupt Requests	1 interrupt to MPU Subsystem (I2C0INT), PRU-ICSS, and Wakeup Processor
DMA Requests	2 DMA requests to EDMA (I2CTXEVT0, I2CRXEVT0)
Physical Address	L4 Wakeup slave port

Table 22-3. I2C(1–2) Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK (Interface/OCP) PD_PER_I2C_FCLK (Func)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt per instance to MPU Subsystem (I2C1INT, I2C2INT)
DMA Requests	2 DMA requests per instance to EDMA (I2CTXEVTx, I2CRXEVTx)
Physical Address	L4 Peripheral slave port

22.2.2 I2C Clock and Reset Management

The I2C controllers have separate bus interface and functional clocks. During power-down mode, the I2C*x*_SCL and I2C*x*_SDA are configured as inputs.

Table 22-4. I2C Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
I2C0 Clock Signals			
PIOCPCLK Interface clock	26 MHz	CLK_M_OSC	pd_wkup_l4_wkup_gclk From PRCM
PISYSCLK Functional clock	48 MHz	PER_CLKOUTM2 / 4	pd_wkup_i2c0_gfclk From PRCM
I2C(1-2) Clock Signals			
PIOCPCLK Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk From PRCM
PISYSCLK Functional clock	48 MHz	PER_CLKOUTM2 / 4	pd_per_ic2_fclk From PRCM

22.2.3 I2C Pin List

The external signals (I2C*x*_SDA, I2C*x*_SCL) on the device use standard LVCMOS I/Os and may not meet full compliance with the I2C specifications for Fast-mode devices for slope control and input filtering (spike suppression) to improve the EMC behavior.

Table 22-5. I2C Pin List

Pin	Type	Description
I2C*x*_SCL	I/OD(1)	I2C serial clock (open drain)
I2C*x*_SDA	I/OD	I2C serial data (open drain)

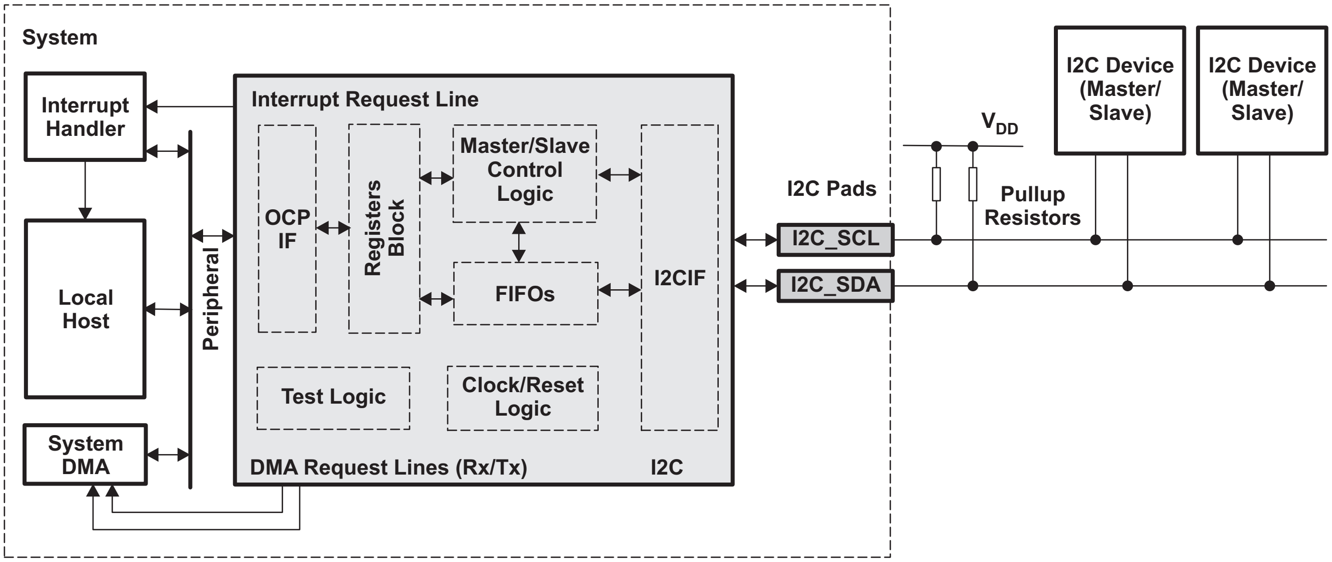
(1) These signals are also used as inputs to re-time or sync data. The associated CONF_<module>_pin_RXACTIVE bit for these signals must be set to 1 to enable the inputs back to the module. It is also recommended to place a 33-ohm resistor in series (close to the processor) on each of these signals to avoid signal reflections.

22.3 Functional Description

22.3.1 Functional Block Diagram

Figure 22-3 shows an example of a system with multiple I2C compatible devices in which the I2C serial ports are all connected together for a two-way transfer from one device to other devices.

Figure 22-3. I2C Functional Block Diagram



The I2C peripheral consists of the following primary blocks:

- A serial interface: one data pin (I2C_SDA) and one clock pin (I2C_SCL).
- Data registers to temporarily hold receive data and transmit data traveling between the I2C_SDA pin and the CPU or the DMA controller.
- Control and status registers
- A peripheral data bus interface to enable the CPU and the DMA controller to access the I2C peripheral registers.
- A clock synchronizer to synchronize the I2C input clock (from the processor clock generator) and the clock on the I2C_SCL pin, and to synchronize data transfers with masters of different clock speeds.
- A prescaler to divide down the input clock that is driven to the I2C peripheral
- A noise filter on each of the two pins, I2C_SDA and I2C_SCL
- An arbitrator to handle arbitration between the I2C peripheral (when it is a master) and another master
- Interrupt generation logic, so that an interrupt can be sent to the CPU
- DMA event generation logic to send an interrupt to the CPU upon reception and data transmission of data.

22.3.2 I2C Master/Slave Contoller Signals

Data is communicated to devices interfacing with the I2C via the serial data line (SDA) and the serial clock line (SCL). These two wires can carry information between a device and others connected to the I2C bus. Both SDA and SCL are bi-directional pins. They must be connected to a positive supply voltage via a pull-up resistor. When the bus is free, both pins are high. The driver of these two pins has an open drain to perform the required wired-AND function.

An example of multiple I2C modules that are connected for a two-way transfer from one device to other devices is shown in Figure 22-4.

Figure 22-4. Multiple I2C Modules Connected

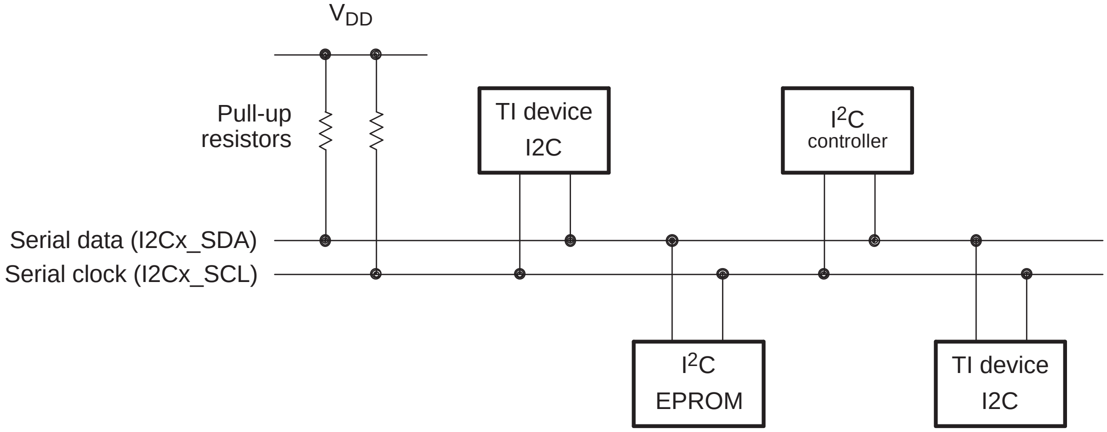


Table 22-6. Signal Pads

	I2C Mode	
Name	**Default Operating Mode**	**Description**
I2C_SCL	In/ Out	I2C serial CLK line Open-drain output buffer. Requires external pull-up resistor (Rp).
I2C_SDA	In/ Out	I2C serial data line Open-drain output buffer. Requires external pull-up resistor (Rp).

22.3.3 I2C Reset

The I2C module can be reset in the following three ways:

- A system reset (PIRSTNA = 0). A device reset causes the system reset. All registers are reset to power up reset values.
- A software reset by setting the SRST bit in the I2C_SYSC register. This bit has exactly the same action on the module logic as the system bus reset. All registers are reset to power up reset values.
- The I2C_EN bit in the I2C_CON register can be used to hold the I2C module in reset. When the system bus reset is removed (PIRSTNA = 1), I2C_EN = 0 keeps the functional part of I2C module in reset state and all configuration registers can be accessed. I2C_EN = 0 does not reset the registers to power up reset values.

Table 22-7. Reset State of I2C Signals

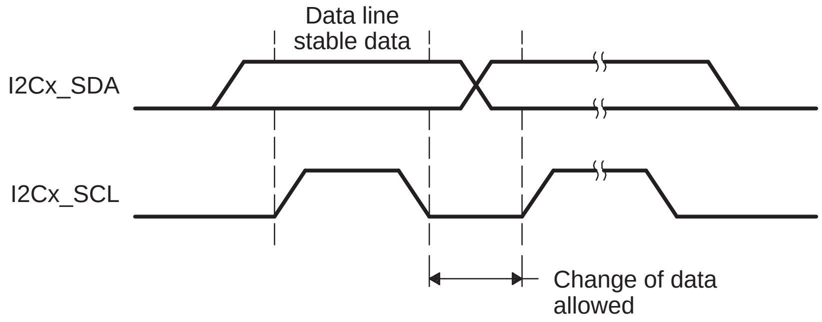
			I2C Reset
Pin	**I/O/Z** (1)	**System Reset**	**(I2C_EN = 0)**
SDA	I/O/Z	High impedance	High impedance
SCL	I/O/Z	High impedance	High impedance

(1) I = Input, O = Outpu, Z = High impedance

22.3.4 Data Validity

The data on the SDA line must be stable during the high period of the clock. The high and low states of the data line can only change when the clock signal on the SCL line is LOW.

Figure 22-5. Bit Transfer on the I2C Bus

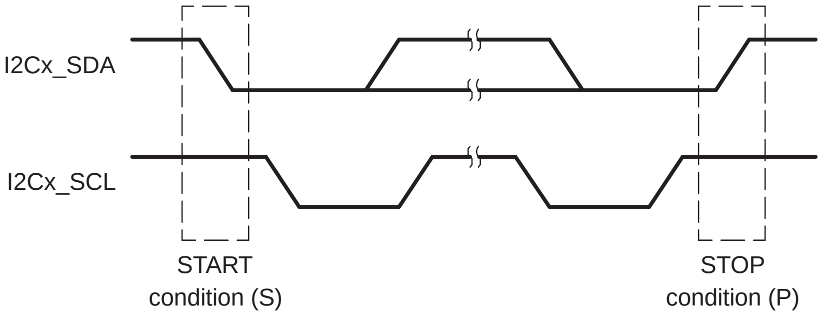


22.3.5 START & STOP Conditions

The I2C module generates START and STOP conditions when it is configured as a master.

- START condition is a high-to-low transition on the SDA line while SCL is high.
- STOP condition is a low-to-high transition on the SDA line while SCL is high.
- The bus is considered to be busy after the START condition (BB = 1) and free after the STOP condition (BB = 0).

Figure 22-6. Start and Stop Condition Events

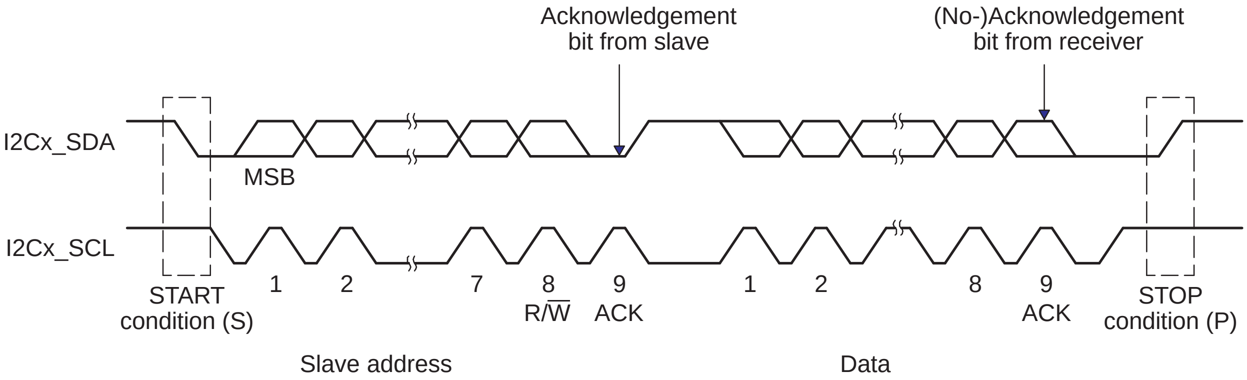


22.3.6 I2C Operation

22.3.6.1 Serial Data Formats

The I2C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte put on the SDA line is 8 bits long. The number of bytes that can be transmitted or received is restricted by the value programmed in the DCOUNT register. The data is transferred with the most significant bit (MSB) first. Each byte is followed by an acknowledge bit from the module if it is in receiver mode.

Figure 22-7. I2C Data Transfer



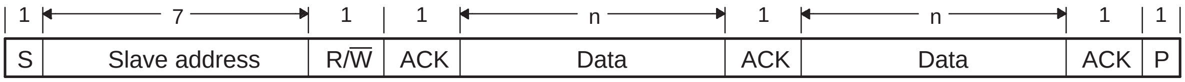
The I2C module supports two data formats, as shown in Figure 22-8:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start condition

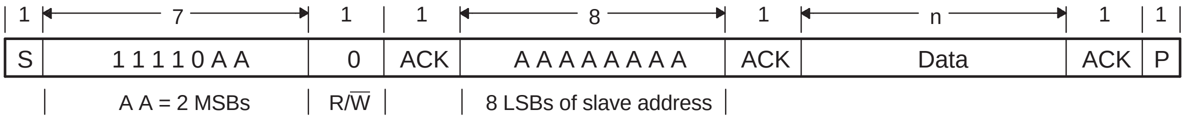
The first byte after a start condition (S) always consists of 8 bits. In the acknowledge mode, an extra bit dedicated for acknowledgment is inserted after each byte. In the addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 LSB R/nW bit. In the addressing formats with 10-bit addresses, the first byte is composed of 7 MSB slave address bits, such as 11110XX, where XX is the two MSB of the 10-bit addresses, and 1 LSB R/nW bit, which is 0 in this case.

The least significant R/nW of the address byte indicates the direction of transmission of the following data bytes. If R/nW is 0, the master writes data into the selected slave; if it is 1, the master reads data out of the slave.

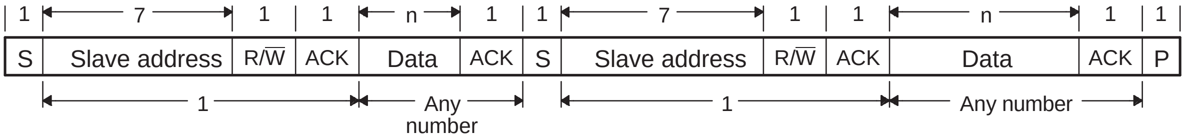
Figure 22-8. I2C Data Transfer Formats



7-Bit Addressing Format



10-Bit Addressing Format



7-Bit Addressing Format With Repeated START Condition

22.3.6.2 Master Transmitter

In this mode, data assembled in one of the previously described data formats is shifted out on the serial data line SDA in synch with the self-generated clock pulses on the serial clock line SCL. The clock pulses are inhibited and SCL held low when the intervention of the processor is required (XUDF) after a byte has been transmitted.

22.3.6.3 Master Receiver

This mode can only be entered from the master transmitter mode. With either of the address formats (Figure 22-8 (a), (b), and (c)), the master receiver is entered after the slave address byte and bit R/W_ has been transmitted, if R/W_ is high. Serial data bits received on bus line SDA are shifted in synch with the self-generated clock pulses on SCL. The clock pulses are inhibited and SCL held low when the intervention of the processor is required (ROVR) after a byte has been transmitted. At the end of a transfer, it generates the stop condition.

22.3.6.4 Slave Transmitter

This mode can only be entered from the slave receiver mode. With either of the address formats (Figure 22-8 (a), (b), and (c)), the slave transmitter is entered if the slave address byte is the same as its own address and bit R/W_ has been transmitted, if R/W_ is high. The slave transmitter shifts the serial data out on the data line SDA in synch with the clock pulses that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the CPU is required (XUDF).

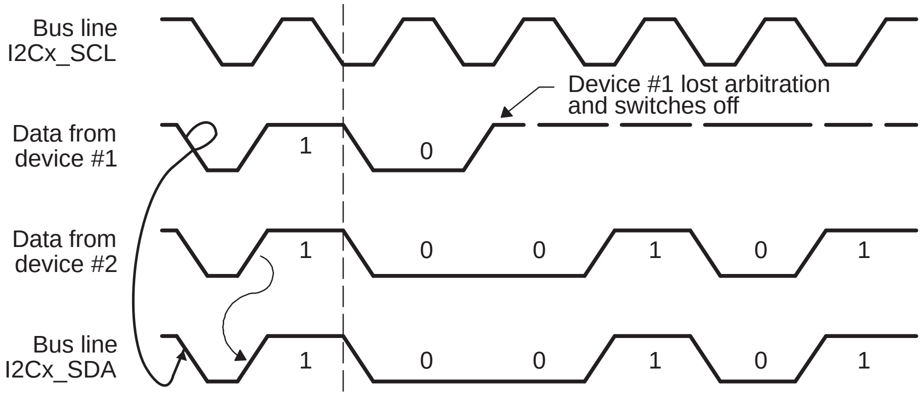
22.3.6.5 Slave Receiver

In this mode, serial data bits received on the bus line SDA are shifted-in in synch with the clock pulses on SCL that are generated by the master device. It does not generate the clock but it can hold clock line SCL low while intervention of the CPU is required (ROVR) following the reception of a byte.

22.3.7 Arbitration

If two or more master transmitters start a transmission on the same bus almost simultaneously, an arbitration procedure is invoked. The arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to the slave receiver mode, sets the arbitration lost (AL) flag, and generates the arbitration lost interrupt. Figure 22-9 shows the arbitration procedure between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. Should two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 22-9. Arbitration Procedure Between Two Master Transmitters



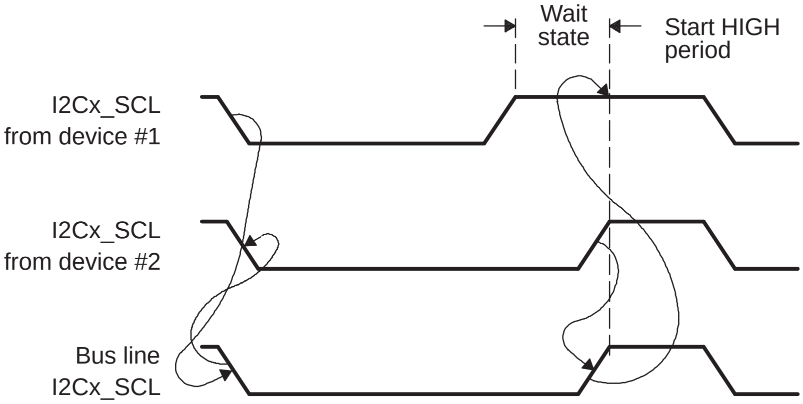
22.3.8 I2C Clock Generation and I2C Clock Synchronization

Under normal conditions, only one master device generates the clock signal, SCL. During the arbitration procedure, however, there are two or more master devices and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that a device that first generates a low period of the clock line overrules the other devices. At this high/low transition, the clock generators of the other devices are forced to start generation of their own low period. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest the length of the high period.

If a device pulls down the clock line for a longer time, the result is that all clock generators must enter the WAIT-state. In this way a slave can slow down a fast master and the slow device can create enough time to store a received byte or to prepare a byte to be transmitted (Clock Stretching). Figure 22-10 illustrates the clock synchronization.

Note: If the SCL or SDA lines are stuck low, the Bus Clear operation is supported. If the clock line (SCL) is stuck low, the preferred procedure is to reset the bus using the hardware reset signal if your I2C devices have hardware reset inputs. If the I2C devices do not have hardware reset inputs, cycle power to the devices to activate the mandatory internal power-on reset (POR) circuit. If the data line (SDA) is stuck low, the master should send nine clock pulses. The device that held the bus low should release it sometime within those nine clocks. If not, use the hardware reset or cycle power to clear the bus.

Figure 22-10. Synchronization of Two I2C Clock Generators



22.3.9 Prescaler (SCLK/ICLK)

The I2C module is operated with a functional clock (SCLK) frequency that can be in a range of 12-100 MHz, according to I2C mode that must be used (an internal ~24 MHz clock (ICLK) is recommended in case of F/S operation mode e). Note that the frequency of the functional clock influences directly the I2C bus performance and timings.

The internal clock used for I2C logic - ICLK - is generated via the I2C prescaler block. The prescaler consists of a 4-bit register - I2C _PSC, and is used to divide the system clock (SCLK) to obtain the internal required clock for the I2C module.

22.3.10 Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less, in the case of F/S mode of operation. It is designed to suppress noise with one ICLK. The noise filter is always one ICLK cycle, regardless of the bus speed. For FS mode (prescaler = 4, ICLK = 24 MHz), the maximum width of the suppressed spikes is 41.6 ns. To ensure a correct filtering, the prescaler must be programmed accordingly.

22.3.11 I2C Interrupts

The I2C module generates 12 types of interrupt: addressed as slave, bus free (stop condition detected), access error, start condition, arbitration-lost, noacknowledge, general call, registers-ready-for-access, receive and transmit data, receive and transmit draining. These 12 interrupts are accompanied with 12 interrupt masks and flags defined in the I2C_IRQEN_SET and respectively I2C_IRQSTS_RAW registers. Note that all these 12 interrupt events are sharing the same hardware interrupt line.

- Addressed As Slave interrupt (AAS) is generated to inform the Local Host that an external master addressed the module as a slave. When this interrupt occurs, the CPU can check the I2C_ACTOA status register to check which of the 4 own addresses was used by the external master to access the module.
- Bus Free interrupt (BF) is generated to inform the Local Host that the I2C bus became free (when a Stop Condition is detected on the bus) and the module can initiate his own I2C transaction.
- Start Condition interrupt (STC) is generated after the module being in idle mode have detected (synchronously or asynchronously) a possible Start Condition on the bus (signalized with WakeUp).
- Access Error interrupt (AERR) is generated if a Data read access is performed while RX FIFO is empty or a Data write access is performed while TX FIFO is full.
- Arbitration lost interrupt (AL) is generated when the I2C arbitration procedure is lost.
- No-acknowledge interrupt (NACK) is generated when the master I2C does not receive acknowledge from the receiver.
- General call interrupt (GC) is generated when the device detects the address of all zeros (8 bits).
- Registers-ready-for-access interrupt (ARDY) is generated by the I2C when the previously programmed address, data, and command have been performed and the status bits have been updated. This

interrupt is used to let the CPU know that the I2C registers are ready for access.

- Receive interrupt/status (RRDY) is generated when there is received data ready to be read by the CPU from the I2C_DATA register (for a complete description of required conditions for interrupt generation, see Section 22.3.14, *FIFO Management*). The CPU can alternatively poll this bit to read the received data from the I2C_DATA register.
- Transmit interrupt/status (XRDY) is generated when the CPU needs to put more data in the I2C_DATA register after the transmitted data has been shifted out on the SDA pin (for a complete description of required conditions for interrupt generation, see Section 22.3.14, *FIFO Management*). The CPU can alternatively poll this bit to write the next transmitted data into the I2C_DATA register.
- Receive draining interrupt (RDR) is generated when the transfer length is not a multiple of threshold value, to inform the CPU that it can read the amount of data left to be transferred and to enable the draining mechanism (see Section 22.3.14.4, *Draining Feature*, for additional details).
- Transmit draining interrupt (XDR) is generated when the transfer length is not a multiple of threshold value, to inform the CPU that it can read the amount of data left to be written and to enable the draining mechanism (see Section 22.3.14.4, *Draining Feature*, for additional details).

When the interrupt signal is activated, the Local Host must read the I2C_IRQSTS_RAW register to define the type of the interrupt, process the request, and then write into these registers the correct value to clear the interrupt flag.

22.3.12 DMA Events

The I2C module can generate two DMA requests events, read (I2C_DMA_RX) and write (I2C_DMA_TX) that can be used by the DMA controller to synchronously read received data from the I2C_DATA or write transmitted data to the I2C_DATA register. The DMA read and write requests are generated in a similar manner as RRDY and XRDY, respectively.

The I2C DMA request signals (I2C_DMA_TX and I2C_DMA_RX) are activated according to Section 22.3.14, *FIFO Management*.

22.3.13 Interrupt and DMA Events

I2C has two DMA channels (Tx and Rx).

I2C has one interrupt line for all the interrupt requests.

For the event and interrupt numbers, see the device-specific datasheet.

22.3.14 FIFO Management

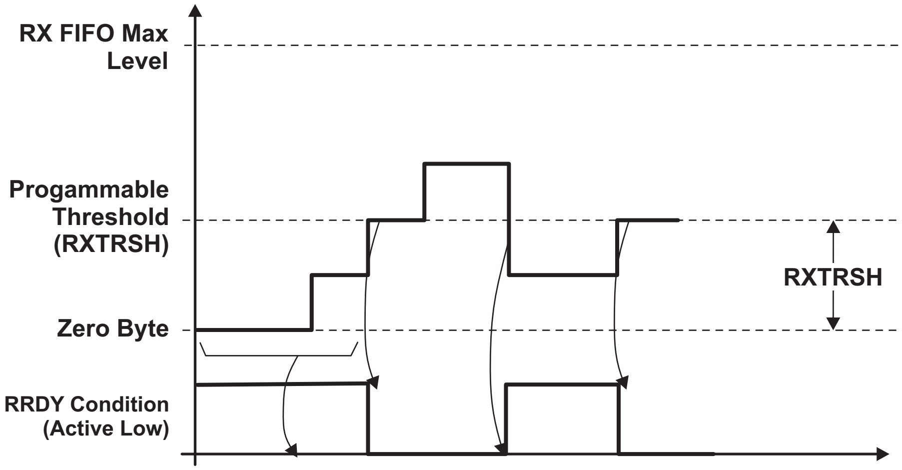
The I2C module implements two internal 32-bytes FIFOs with dual clock for RX and TX modes. The depth of the FIFOs can be configured at integration via a generic parameter which will also be reflected in I2C_IRQSTS_RAW.FIFODEPTH register.

22.3.14.1 FIFO Interrupt Mode Operation

In FIFO interrupt mode (relevant interrupts enabled via I2C_IRQEN_SET register), the processor is informed of the status of the receiver and transmitter by an interrupt signal. These interrupts are raised when receive/transmit FIFO threshold (defined by I2C_BUF.TXTRSH or I2C_BUF.RXTRSH) are reached; the interrupt signals instruct the Local Host to transfer data to the destination (from the I2C module in receive mode and/or from any source to the I2C FIFO in transmit mode).

Figure 22-11 and Figure 22-12, respectively, illustrate receive and transmit operations from FIFO management point of view.

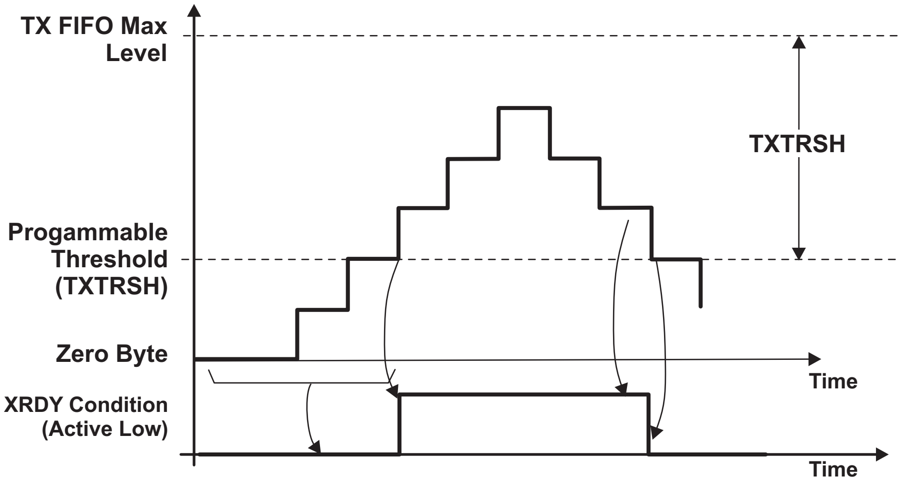
Figure 22-11. Receive FIFO Interrupt Request Generation



Note that in Figure 22-11, the RRDY Condition illustrates that the condition for generating a RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the CPU by writing a 1 in the corresponding interrupt flag. If the condition is still present after clearing the previous interrupt, another interrupt request will be generated.

In receive mode, RRDY interrupt is not generated until the FIFO reaches its receive threshold. Once low, the interrupt can only be de-asserted when the Local Host has handled enough bytes to make the FIFO level below threshold. For each interrupt, the Local Host can be configured to read an amount of bytes equal with the value of the RX FIFO threshold + 1.

Figure 22-12. Transmit FIFO Interrupt Request Generation



Note that in Figure 22-12, the XRDY Condition illustrates that the condition for generating a XRDY interrupt is achieved. The interrupt request is generated when this condition is achieved (when TX FIFO is empty, or the TX FIFO threshold is not reached and there are still data bytes to be transferred in the TX FIFO), and it can be cleared only by the CPU by writing a 1 in the corresponding interrupt flag after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request will be generated.

Note that in interrupt mode, the module offers two options for the CPU application to handle the interrupts:

- When detecting an interrupt request (XRDY or RRDY type), the CPU can write/read one data byte to/from the FIFO and then clear the interrupt. The module will not reassert the interrupt until the interrupt condition is not met.

- When detecting an interrupt request (XRDY or RRDY type), the CPU can be programmed to write/read the amount of data bytes specified by the corresponding FIFO threshold (I2C_BUF.TXTRSH + 1 or I2C_BUF.RXTRSH + 1). In this case, the interrupt condition will be cleared and the next interrupt will be asserted again when the XRDY or RRDY condition will be again met.

If the second interrupt serving approach is used, an additional mechanism (draining feature) is implemented for the case when the transfer length is not a multiple of FIFO threshold (see Section 22.3.14.4, *Draining Feature*).

In slave TX mode, the draining feature cannot be used, since the transfer length is not known at the configuration time, and the external master can end the transfer at any point by not acknowledging one data byte.

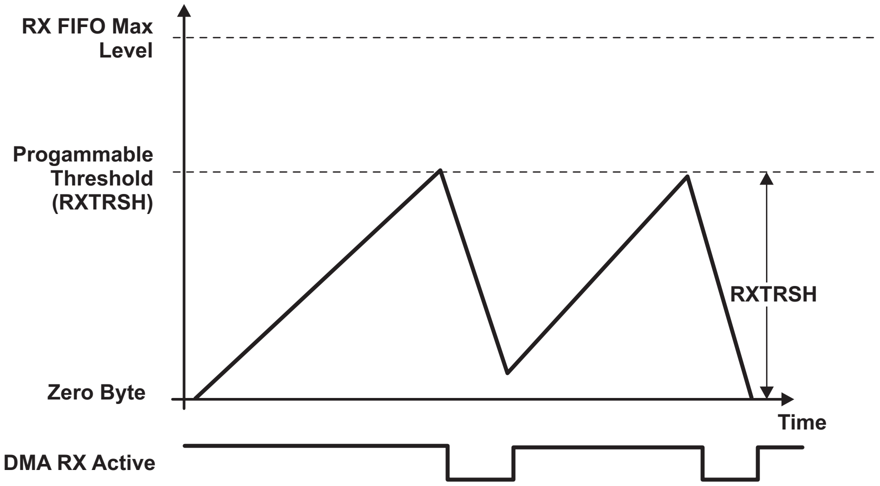
22.3.14.2 FIFO Polling Mode Operation

In FIFO polled mode (I2C_IRQEN_SET.XRDY_IE and I2C_IRQEN_SET.RRDY_IE disabled and DMA disabled), the status of the module (receiver or transmitter) can be checked by polling the XRDY and RRDY status registers (I2C_IRQSTS_RAW) (RDR and XDR can also be polled if draining feature must be used). The XRDY and RRDY flags are accurately reflecting the interrupt conditions mentioned in Interrupt Mode. This mode is an alternative to the FIFO interrupt mode of operation, where the status of the receiver and transmitter is automatically known by means of interrupts sent to the CPU.

22.3.14.3 FIFO DMA Mode Operation

In receive mode, a DMA request is generated as soon as the receive FIFO exceeds its threshold level defined in the threshold level register (I2C_BUF.RXTRSH +1). This request should be de-asserted when the number of bytes defined by the threshold level has been read by the DMA, by setting the I2C_DMARXEN_CLR.DMARX_EN_CLR field.

Figure 22-13. Receive FIFO DMA Request Generation



In transmit mode, a DMA request is automatically asserted when the transmit FIFO is empty. This request should be de-asserted when the number of bytes defined by the number in the threshold register (I2C_BUF.TXTHRS+1) has been written in the FIFO by the DMA, by setting the I2C_DMATXEN_CLR. DMATX_EN_CLR field. If an insufficient number of characters are written, then the DMA request will remain active. Figure 22-14 and Figure 22-15 illustrate DMA TX transfers with different values for TXTRSH.

Figure 22-14. Transmit FIFO DMA Request Generation (High Threshold)

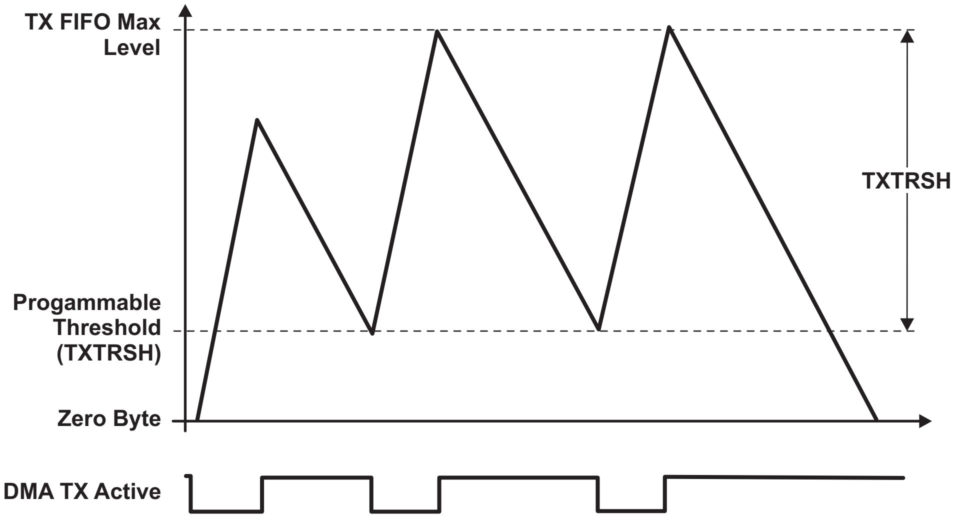


Figure 22-15. Transmit FIFO DMA Request Generation (Low Threshold)

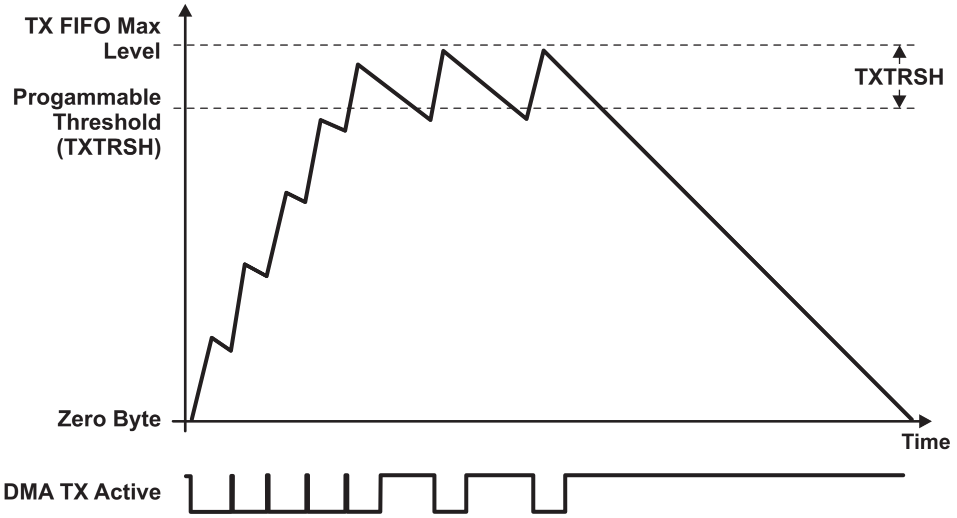

Note that also in DMA mode it is possible to have a transfer whose length is not multiple of the configured FIFO threshold. In this case, the DMA draining feature is also used for transferring the additional bytes of the transfer (see Section 22.3.14.4, *Draining Feature*, for additional details).

According to the desired operation mode, the programmer must set the FIFO thresholds according to the following table (note that only the interface/OCP side thresholds can be programmed; the I2C side thresholds are default equals to 1). Note that the thresholds must be set consistent with the DMA channel length.

In I2C Slave RX Mode, the Local Host can program the RX threshold with the desired value, and use the FIFO draining feature at the end of the I2C transfer to extract from the FIFO the remaining bytes if the threshold is not reached (see Section 22.3.14.4, *Draining Feature*, for additional details).

Note that in I2C Slave TX Mode, the TX FIFO threshold should be set to 1 (I2C_BUF.TXTRSH=0, default value), since the length of the transfer may not be known at configuration time. In this way, the interrupt (or accordingly, DMA) requests will be generated for each byte requested by the remote I2C master to be transferred over the I2C bus. This configuration will prevent the I2C core to request additional data from the CPU or from the DMA controller (using IRQ or DMA), data that will eventually not be extracted from the FIFO by the external master (which can use not acknowledge at any time to end the transfer). If the TX threshold is not set to 1, the module will generate an interrupt or assert a DMA only when the external master requests a byte and the FIFO is empty. However, in this case the TX FIFO will require to be cleared at the end of the transfer.

The I2C module offers the possibility to the user to clear the RX or TX FIFO. This is achieved through I2C_BUF.RXFIFO_CLR and I2C_BUF.TXFIFO_CLR registers, which act like software reset for the FIFOs. In DMA mode, these bits will also reset the DMA state machines.

The FIFO clearing feature can be used when the module is configured as a transmitter, the external receiver responds with a NACK in the middle of the transfer, and there is still data in TX FIFO waiting to be transferred.

On the Functional (I2C) domain, the thresholds can always be considered equal to 1. This means that the I2C Core can start transferring data on the I2C bus whenever it has data in the FIFOs (FIFO is not empty).

22.3.14.4 Draining Feature

The Draining Feature is implemented by the I2C core for handling the end of the transfers whose length is not a multiple of FIFO threshold value, and offers the possibility to transfer the remaining amount of bytes (since the threshold is not reached).

Note that this feature prevents the CPU or the DMA controller to attempt more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having in the FIFO less bytes than the configured DMA transfer length). Otherwise, an Access Error interrupt will be generated (see I2C_IRQSTS_RAW.AERR interrupt).

The Draining mechanism will generate an interrupt (I2C_IRQSTS_RAW.RDR or I2C_IRQSTS_RAW.XDR) at the end of the transfer informing the CPU that it needs to check the amount of data left to be transferred (I2C_BUFSTAT.TXSTAT or RXSTAT) and to enable the Draining Feature of the DMA controller if DMA mode is enabled (by re-configuring the DMA transfer length according to this value), or perform only the required number of data accesses, if DMA mode is disabled.

In receiving mode (master or slave), if the RX FIFO threshold is not reached but the transfer was ended on the I2C bus and there is still data left in the FIFO (less than the threshold), the receive draining interrupt (I2C_IRQSTS_RAW.RDR) will be asserted to inform the local host that it can read the amount of data in the FIFO (I2C_BUFSTAT.RXSTAT). The CPU will perform a number of data read accesses equal with RXSTAT value (if interrupt or polling mode) or re-configure the DMA controller with the required value in order to drain the FIFO.

In master transmit mode, if the TX FIFO threshold is not reached but the amount of data remaining to be written in the FIFO is less than TXTRSH, the transmit draining interrupt (I2C_IRQSTS_RAW.XDR) will be asserted to inform the local host that it can read the amount of data remained to be written in the TX FIFO (I2C_BUFSTAT.TXSTAT). The CPU will need to write the required number of data bytes (specified by TXSTAT value) or re-configure the DMA controller with the required value in order to transfer the last bytes to the FIFO.

Note that in master mode, the CPU can alternatively skip the checking of TXSTAT and RXSTAT values since it can obtain internally this information (by computing DATACOUNT modulo TX/RXTHRSH).

The draining feature is disabled by default, and it can be enabled using I2C_IRQEN_SET.XDR_IE or I2C_IRQEN_SET.RDR_IE registers (default disabled) only for the transfers with length not equal with the threshold value.

22.3.15 How to Program I2C

22.3.15.1 Module Configuration Before Enabling the Module

1. Program the prescaler to obtain an approximately 12-MHz I2C module clock (I2C_PSC = x; this value is to be calculated and is dependent on the System clock frequency).
2. Program the I2C clock to obtain 100 Kbps or 400 Kbps (SCLL = x and SCLH = x; these values are to be calculated and are dependent on the System clock frequency).
3. Configure its own address (I2C_OA = x) - only in case of I2C operating mode (F/S mode).
4. Take the I2C module out of reset (I2C_CON:I2C_EN = 1).

22.3.15.2 Initialization Procedure

1. Configure the I2C mode register (I2C_CON) bits.
2. Enable interrupt masks (I2C_IRQEN_SET), if using interrupt for transmit/receive data.
3. Enable the DMA (I2C_BUF and I2C_DMA/RX/TX/EN_SET) and program the DMA controller) - only in case of I2C operating mode (F/S mode), if using DMA for transmit/receive data.

22.3.15.3 Configure Slave Address and DATA Counter Registers

In master mode, configure the slave address (I2C_SA = x) and the number of byte associated with the transfer (I2C_CNT = x).

22.3.15.4 Initiate a Transfer

Poll the bus busy (BB) bit in the I2C status register (I2C_IRQSTS_RAW). If it is cleared to 0 (bus not busy), configure START/STOP (I2C_CON: STT / I2C_CON: STP condition to initiate a transfer) - only in case of I2C operating mode (F/S mode).

22.3.15.5 Receive Data

Poll the receive data ready interrupt flag bit (RRDY) in the I2C status register (I2C_IRQSTS_RAW), use the RRDY interrupt (I2C_IRQEN_SET.RRDY_IE set) or use the DMA RX (I2C_BUF.RDMA_EN set together with I2C_DMARXEN_SET) to read the received data in the data receive register (I2C_DATA). Use draining feature (I2C_IRQSTS_RAW.RDR enabled by I2C_IRQEN_SET.RDR_IE)) if the transfer length is not equal with FIFO threshold.

22.3.15.6 Transmit Data

Poll the transmit data ready interrupt flag bit (XRDY) in the I2C status register (I2C_IRQSTS_RAW), use the XRDY interrupt (I2C_IRQEN_SET.XRDY_IE set) or use the DMA TX (I2C_BUF.XDMA_EN set together with I2C_DMATXEN_SET) to write data into the data transmit register (I2C_DATA). Use draining feature (I2C_IRQSTS_RAW.XDR enabled by I2C_IRQEN_SET.XDR_IE)) if the transfer length is not equal with FIFO threshold.

22.3.16 I2C Behavior During Emulation

To configure the I2C to stop during emulation suspend events (for example, debugger breakpoints), set up the I2C and the Debug Subsystem:

1. Set I2C_SYSTEST.FREE=0. This will allow the Suspend_Control signal from the Debug Subsystem (Chapter 31) to stop and start the I2C. Note that if FREE=1, the Suspend_Control signal is ignored and the I2C is free running regardless of any debug suspend event. This FREE bit gives local control from a module perspective to gate the suspend signal coming from the Debug Subsystem.
2. Set the appropriate xxx_Suspend_Control register = 0x9, as described in Section 31.1.1.1, *Debug Suspend Support for Peripherals*. Choose the register appropriate to the peripheral you want to suspend during a suspend event.

22.4 I2C Registers

22.4.1 I2C Registers

Table 22-8 lists the memory-mapped registers for the I2C. All register offset addresses not listed in Table 22-8 should be considered as reserved locations and the register contents should not be modified.

Table 22-8. I2C Registers

Offset	Acronym	Register Name	Section
0h	I2C_REVNB_LO	Module Revision Register (low bytes)	Section 22.4.1.1
4h	I2C_REVNB_HI	Module Revision Register (high bytes)	Section 22.4.1.2
10h	I2C_SYSC	System Configuration Register	Section 22.4.1.3
24h	I2C_IRQSTS_RAW	I2C Status Raw Register	Section 22.4.1.4

22.4.1.1 I2C_REVNB_LO Register (Offset = 0h) [reset = 0h]

I2C_REVNB_LO is shown in Figure 22-16 and described in Table 22-9.

Return to Summary Table.

This read-only register contains the hard-coded revision number of the module. A write to this register has no effect. I2C controller with interrupt using interrupt vector register (I2C_IV) is revision 1.x. I2C controller with interrupt using status register bits (I2C_IRQSTATUS_RAW) is revision 2.x.

R-0h			R/W-0h		R/W-0h	R/W-0h	R/W-0h

Table 22-11. I2C_SYSC Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	
9-8	CLKACTIVITY	R/W	0h	Clock Activity selection bits. Those bits (one bit for each clock signal present on the boundary of the module) are set to 1 to disable external clock gating mechanism in Idle Mode. Values after reset are low (for both 2 bits). Note: If the System (functional) Clock is cut-off, the module will assert a WakeUp event when it asynchronously detects a Start Condition on the I2C Bus. Note that in this case the first transfer will not be taken into account by the module (NACK will be detected by the external master). 0h = Both clocks can be cut off 1h = Only Interface/OCP clock must be kept active; system clock can be cut off 2h = Only system clock must be kept active; Interface/OCP clock can be cut off 3h = Both clocks must be kept active
7-5	RESERVED	R	0h	
4-3	IDLEMODE	R/W	0h	Idle Mode selection bits. These two bits are used to select one of the idle mode operation mechanisms. Value after reset is 00 (Force Idle). 1h = NO_IDLE 2h = SMART_IDLE 3h = SMART_IDLE_WAKEUP
2	ENAWAKEUP	R/W	0h	Enable Wakeup control bit. When this bit is set to 1, the module enables its own wakeup mechanism. Value after reset is low. 0h = Wakeup mechanism is disabled 1h = Wakeup mechanism is enabled

Table 22-11. I2C_SYSC Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	SRST	R/W	0h	SoftReset bit. When this bit is set to 1, entire module is reset as for the hardware reset. This bit is automatically cleared to 0 by the core and it is only reset by the hardware reset. During reads, it always returns 0. Value after reset is low. 0h = Normal mode 1h = The module is reset
0	AUTOIDLE	R/W	0h	Autoidle bit. When this bit is set to 1, the module activates its own idle mode mechanism. By evaluating its internal state, the module can decide to gate part of his internal clock tree in order to improve the overall power consumption. Value after reset is high. 0h = Auto Idle mechanism is disabled 1h = Auto Idle mechanism is enabled

22.4.1.4 I2C_IRQSTS_RAW Register (Offset = 24h) [reset = 0h]

I2C_IRQSTS_RAW is shown in Figure 22-19 and described in Table 22-12.

Return to Summary Table.

This register provides core status information for interrupt handling, showing all active events (enabled and not enabled). The fields are read-write. Writing a 1 to a bit will set it to 1, that is, trigger the IRQ (mostly for debug). Writing a 0 will have no effect, that is, the register value will not be modified. Only enabled, active events will trigger an actual interrupt request on the IRQ output line.

Table 22-12. I2C_IRQSTS_RAW Register Field Descriptions

Bit	Field	Type	Reset	Description
31-15	RESERVED	R	0h	
14	XDR	R/W	0h	Transmit draining IRQ status. I2C Master Transmit mode only. This read/clear only bit is set to 1 when the module is configured as a master transmitter, the TX FIFO level is below the configured threshold (TXTRSH) and the amount of data still to be transferred is less than TXTRSH. When this bit is set to 1 by the core, CPU must read the I2C_BUFSTAT.TXSTAT register in order to check the amount of data that need to be written in the TX FIFO. Then, according to the mode set (DMA or interrupt), the CPU can enable the DMA draining feature of the DMA controller with the number of data bytes to be transferred (I2C_BUFSTAT.TXSTAT), or generate write data accesses according to this value (IRQ mode). The interrupt needs to be cleared after the DMA controller was reconfigured (if DMA mode enabled), or before generating data accesses to the FIFO (if IRQ mode enabled). If the corresponding interrupt was enabled, an interrupt is signaled to the local host. The CPU can also poll this bit. For more details about TDR generation, refer to the FIFO Management subsection. The CPU can only clear this bit by writing a 1 into the I2C_IRQSTS register. A write 0 has no effect. Value after reset is low. 0h (R/W) = Transmit draining inactive 1h (R/W) = Transmit draining enabled

Table 22-12. I2C_IRQSTS_RAW Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	RDR	R/W	0h	Receive draining IRQ status. I2C Receive mode only. This read/clear only bit is set to 1 when the module is configured as a receiver, a stop condition was received on the bus and the RX FIFO level is below the configured threshold (RXTRSH). When this bit is set to 1 by the core, CPU must read the I2C_BUFSTAT.RXSTAT register in order to check the amount of data left to be transferred from the FIFO. Then, according to the mode set (DMA or interrupt), the CPU needs to enable the draining feature of the DMA controller with the number of data bytes to be transferred (I2C_BUFSTAT.RXSTAT), or generate read data accesses according to this value (IRQ mode). The interrupt needs to be cleared after the DMA controller was reconfigured (if DMA mode enabled), or before generating data accesses to the FIFO (if IRQ mode enabled). If the corresponding interrupt was enabled, an interrupt is signaled to the local host. The CPU can also poll this bit. For more details about RDR generation, refer to the FIFO Management subsection. The CPU can only clear this bit by writing a 1 into the I2C_IRQSTS register. A write 0 has no effect. Value after reset is low. 0h (R/W) = Receive draining inactive 1h (R/W) = Receive draining enabled
12	BB	R	0h	This read-only bit indicates the state of the serial bus. In slave mode, on reception of a start condition, the device sets BB to 1. BB is cleared to 0 after reception of a stop condition. In master mode, the software controls BB. To start a transmission with a start condition, MST, TRX, and STT must be set to 1 in the I2C_CON register. To end a transmission with a stop condition, STP must be set to 1 in the I2C_CON register. When BB = 1 and STT = 1, a restart condition is generated. Value after reset is low. 0h (R/W) = Bus is free 1h (R/W) = Bus is occupied
11	ROVR	R/W	0h	Receive overrun status. Writing into this bit has no effect. I2C receive mode only. This read-only bit indicates whether the receiver has experienced overrun. Overrun occurs when the shift register is full and the receive FIFO is full. An overrun condition does not result in a data loss the peripheral is just holding the bus (low on SCL) and prevents other bytes from being received. ROVR is set to 1 when the I2C has recognized an overrun. ROVR is clear when reading I2C_DATA register, or when resetting the I2C (I2C_CON:I2C_EN = 0). Value after reset is low. 0h (R/W) = Normal operation 1h (R/W) = Receiver overrun

Table 22-12. I2C_IRQSTS_RAW Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10	XUDF	R/W	0h	Transmit underflow status. Writing into this bit has no effect. I2C transmit mode only. This read-only bit indicates whether the transmitter has experienced underflow. In master transmit mode, underflow occurs when the shift register is empty, the transmit FIFO is empty, and there are still some bytes to transmit (DCOUNT 0). In slave transmit mode, underflow occurs when the shift register is empty, the transmit FIFO is empty, and there are still some bytes to transmit (read request from external I2C master). XUDF is set to 1 when the I2C has recognized an underflow. The core holds the line till the underflow cause has disappeared. XUDF is clear when writing I2C_DATA register or resetting the I2C (I2C_CON:I2C_EN = 0). Value after reset is low. 0h (R/W) = Normal operation 1h (R/W) = Transmit underflow
9	AAS	R/W	0h	Address recognized as slave IRQ status. I2C mode only. This read only bit is set to 1 by the device when it has recognized its own slave address (or one of the alternative own addresses), or an address of all zeros (8 bits). When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. This bit can be cleared in 2 ways: One way is if the interrupt was enabled, it will be cleared by writing 1 into the I2C_IRQSTS register (writing 0 has no effect). The other way is if the interrupt was not enabled, the AAS bit is reset to 0 by restart or stop. Value after reset is low. 0h = No action 1h (R/W) = Address recognized
8	BF	R/W	0h	I2C mode only. This read only bit is set to 1 by the device when the I2C bus became free (after a transfer is ended on the bus stop condition detected). This interrupt informs the Local Host that it can initiate its own I2C transfer on the bus. When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can only clear this bit by writing a 1 into the I2C_IRQSTS register. Writing 0 has no effect. Value after reset is low. 0h (R/W) = No action 1h (R/W) = Bus Free
7	AERR	R/W	0h	Access Error IRQ status. I2C mode only. This read/clear only bit is set to 1 by the device if an Interface/OCP write access is performed to I2C_DATA while the TX FIFO is full or if an Interface/OCP read access is performed to the I2C_DATA while the RX FIFO is empty. Note that, when the RX FIFO is empty, a read access will return to the previous read data value. When the TX FIFO is full, a write access is ignored. In both events, the FIFO pointers will not be updated. When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can only clear this bit by writing a 1 into the I2C_IRQSTS register. Writing 0 has no effect. Value after reset is low. 0h = No action 1h (R/W) = Access Error

Table 22-12. I2C_IRQSTS_RAW Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	STC	R/W	0h	Start Condition IRQ status. I2C mode only. This read/clear only bit is set to 1 by the device if previously the module was in idle mode and a start condition was asynchronously detected on the I2C Bus and signalized with an Wakeup (if the I2C_SYSC.ClockActivity allows the system clock to be cut-off). When the Active Mode will be restored and the interrupt generated, this bit will indicate the reason of the wakeup. Note 1: The corresponding interrupt for this bit should be enabled only if the module was configured to allow the possibility of cutting-off the system clock while in Idle State (I2C_SYSC.ClockActivity = 00 or 01). Note 2: The first transfer (corresponding to the detected start condition) will be lost (not taken into account by the module) and it will be used only for generating the WakeUp enable for restoring the Active Mode of the module. On the I2C line, the external master which generated the transfer will detect this behavior as a not acknowledge to the address phase and will possibly restart the transfer. The CPU can only clear this bit by writing a 1 into the I2C_IRQSTS register. Writing 0 has no effect. Value after reset is low. 0h (R/W) = No action 1h (R/W) = Start Condition detected
5	GC	R/W	0h	General call IRQ status. Set to '1' by core when General call address detected and interrupt signaled to MPUSS. Write '1' to clear. I2C mode only. This read/clear only bit is set to 1 by the device if it detects the address of all zeros (8 bits) (general call). When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can only clear this bit by writing a 1 into the I2C_IRQSTS register. Writing 0 has no effect. Note: When this bit is set to 1, AAS also reads as 1. Value after reset is low. 0h (R/W) = No general call detected 1h (R/W) = General call address detected

Table 22-12. I2C_IRQSTS_RAW Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	XRDY	R/W	0h	Transmit data ready IRQ status. Set to '1' by core when transmitter and when new data is requested. When set to '1' by core, an interrupt is signaled to MPUSS. Write '1' to clear. Transmit mode only (I2C mode). This read/clear only bit (XRDY) is set to 1 when the I2C peripheral is a master or slave transmitter, the CPU needs to send data through the I2C bus, and the module (transmitter) requires new data to be served. Note that a master transmitter requests new data if the FIFO TX level is below the threshold (TXTRSH) and the required amount of data remained to be transmitted (I2C_BUFSTAT.TXSTAT) is greater than the threshold. A slave transmitter requests new data when the FIFO TX level is below the threshold (if TXTRSH > 1), or anytime there is a read request from external master (for each acknowledge received from the master), if TXTRSH = 1. When this bit is set to 1 by the core, an interrupt is signaled to the local host if the interrupt was enabled. The CPU can also poll this bit (refer to the FIFO Management subsection for details about XRDY generation). The CPU can only clear this bit by writing a 1 into the I2C_IRQSTS register. Writing 0 has no effect. Note: If the DMA transmit mode is enabled (I2C_BUF.XDMA_EN is set, together with I2C_DMATXEN_SET), this bit is forced to 0 and no interrupt will be generated instead, a DMA TX request to the main DMA controller of the system is generated. Value after reset is low. 0h (R/W) = Transmission ongoing 1h (R/W) = Transmit data ready
3	RRDY	R/W	0h	Receive mode only (I2C mode). This read/clear only RRDY is set to 1 when the RX FIFO level is above the configured threshold (RXTRSH). When this bit is set to 1 by the core, CPU is able to read new data from the I2C_DATA register. If the corresponding interrupt was enabled, an interrupt is signaled to the local host. The CPU to read the received data in I2C_DATA register can also poll this bit (refer to the FIFO Management subsection for details about RRDY generation). The CPU can only clear this bit by writing a 1 into the I2C_IRQSTS register. A write 0 has no effect. If the DMA receive mode is enabled (I2C_BUF.RDMA_EN is set, together with I2C_DMARXENABLE_SET), this bit is forced to 0 and no interrupt will be generated instead a DMA RX request to the main DMA controller of the system is generated. Value after reset is low. 0h (R/W) = Receive FIFO threshold not reached 1h (R/W) = Receive data ready for read (RX FIFO threshold reached)

Table 22-12. I2C_IRQSTS_RAW Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	ARDY	R/W	0h	I2C mode only. This read/clear only bit, when set to 1, indicates that the previously programmed data and command (receive or transmit, master or slave) has been performed and status bit has been updated. The CPU uses this flag to let it know that the I2C registers are ready to be accessed again. The CPU can only clear this bit by writing a 1 into the I2C_IRQSTS register. A write 0 has no effect. Mode: I2C Master transmit, Others: STP = 1, ARDY Set Condition: DCOUNT = 0. Mode: I2C Master receive, Others: STP = 1, ARDY Set Condition: DCOUNT = 0 and receiver FIFO empty Mode: I2C Master transmit, Others: STP = 0, ARDY Set Condition: DCOUNT passed 0 Mode: I2C Master receive, Others: STP = 0, ARDY Set Condition: DCOUNT passed 0 and receiver FIFO empty Mode: I2C Master transmit, Others: n/a, ARDY Set Condition: Stop or restart condition received from master Mode: I2C Slave receive, Others: n/a, ARDY Set Condition: Stop or restart condition and receiver FIFO empty Value after reset is low. 0h (R/W) = No action 1h (R/W) = Access ready
1	NACK	R/W	0h	No acknowledgment IRQ status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPUSS. Write '1' to clear this bit. I2C mode only. The read/clear only No Acknowledge flag bit is set when the hardware detects No Acknowledge has been received. When a NACK event occurs on the bus, this bit is set to 1, the core automatically ends the transfer and clears the MST/STP bits in the I2C_CON register and the I2C becomes a slave. Clearing the FIFOs from remaining data might be required. The CPU can only clear this bit by writing a 1 into the I2C_IRQSTS register. Writing 0 has no effect. Value after reset is low. 0h (R/W) = Normal operation 1h (R/W) = Not Acknowledge detected
0	AL	R/W	0h	Arbitration lost IRQ status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to MPUSS. During reads, it always returns 0. I2C mode only. The read/clear only Arbitration Lost flag bit is set to 1 when the device (configured in master mode) detects it has lost an arbitration (in Address Phase). This happens when two or more masters initiate a transfer on the I2C bus almost simultaneously or when the I2C attempts to start a transfer while BB (bus busy) is 1. When this is set to 1 due to arbitration lost, the core automatically clears the MST/STP bits in the I2C_CON register and the I2C becomes a slave receiver. The CPU can only clear this bit by writing a 1 to the I2C_IRQSTS register. Writing 0 has no effect. Value after reset is low. 0h (R/W) = Normal operation 1h (R/W) = Arbitration lost detected

22.4.1.5 I2C_IRQSTS Register (Offset = 28h) [reset = 0h]

I2C_IRQSTS is shown in Figure 22-20 and described in Table 22-13.

Return to Summary Table.

This register provides core status information for interrupt handling, showing all active and enabled events and masking the others. The fields are read-write. Writing a 1 to a bit will clear it to 0, that is, clear the IRQ. Writing a 0 will have no effect, that is, the register value will not be modified. Only enabled, active events will trigger an actual interrupt request on the IRQ output line. For all the internal fields of the I2C_IRQSTATUS register, the descriptions given in the I2C_IRQSTATUS_RAW subsection are valid.

14	XDR	R/W	0h	Transmit draining IRQ enabled status. 0h = Transmit draining inactive 1h = Transmit draining enabled
13	RDR	R/W	0h	Receive draining IRQ enabled status. 0h = Receive draining inactive 1h = Receive draining enabled
12	BB	R/W	0h	Bus busy enabled status. Writing into this bit has no effect. 0h = Bus is free 1h = Bus is occupied
11	ROVR	R/W	0h	Receive overrun enabled status. Writing into this bit has no effect. 0h = Normal operation 1h = Receiver overrun
10	XUDF	R/W	0h	Transmit underflow enabled status. Writing into this bit has no effect. 0h = Normal operation 1h = Transmit underflow
9	AAS	R/W	0h	Address recognized as slave IRQ enabled status. 0h = No action 1h = Address recognized
8	BF	R/W	0h	Bus Free IRQ enabled status. 0h = No action 1h = Bus free

Table 22-13. I2C_IRQSTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	AERR	R/W	0h	Access Error IRQ enabled status. 0h = No action 1h = Access error
6	STC	R/W	0h	Start Condition IRQ enabled status. 0h = No action 1h = Start condition detected
5	GC	R/W	0h	General call IRQ enabled status. Set to '1' by core when General call address detected and interrupt signaled to MPUSS. Write '1' to clear. 0h = No general call detected 1h = General call address detected
4	XRDY	R/W	0h	Transmit data ready IRQ enabled status. Set to '1' by core when transmitter and when new data is requested. When set to '1' by core, an interrupt is signaled to MPUSS. Write '1' to clear. 0h = Transmission ongoing 1h = Transmit data ready
3	RRDY	R/W	0h	Receive data ready IRQ enabled status. Set to '1' by core when receiver mode, a new data is able to be read. When set to '1' by core, an interrupt is signaled to MPUSS. Write '1' to clear. 0h = No data available 1h = Receive data available
2	ARDY	R/W	0h	Register access ready IRQ enabled status. When set to '1' it indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPUSS. Write '1' to clear. 0h = Module busy 1h = Access ready
1	NACK	R/W	0h	No acknowledgment IRQ enabled status. Bit is set when No Acknowledge has been received, an interrupt is signaled to MPUSS. Write '1' to clear this bit. 0h = Normal operation 1h = Not Acknowledge detected
0	AL	R/W	0h	Arbitration lost IRQ enabled status. This bit is automatically set by the hardware when it loses the Arbitration in master transmit mode, an interrupt is signaled to MPUSS. During reads, it always returns 0. 0h = Normal operation 1h = Arbitration lost detected

22.4.1.6 I2C_IRQEN_SET Register (Offset = 2Ch) [reset = 0h]

I2C_IRQEN_SET is shown in Figure 22-21 and described in Table 22-14.

Return to Summary Table.

All 1-bit fields enable a specific interrupt event to trigger an interrupt request. Writing a 1 to a bit will enable the field. Writing a 0 will have no effect, that is, the register value will not be modified. For all the internal fields of the I2C_IRQENABLE_SET register, the descriptions given in the I2C_IRQSTATUS_RAW subsection are valid.

22.4.1.8 I2C_WE Register (Offset = 34h) [reset = 0h]

I2C_WE is shown in Figure 22-23 and described in Table 22-16.

Return to Summary Table.

Every 1-bit field in the I2C_WE register enables a specific (synchronous) IRQ request source to generate an asynchronous wakeup (on the appropriate swakeup line). When a bit location is set to 1 by the local host, a wakeup is signaled to the local host if the corresponding event is captured by the core of the I2C controller. Value after reset is low (all bits). There is no need for an Access Error WakeUp event, since this event occurs only when the module is in Active Mode (for Interface/OCP accesses to FIFO) and is signaled by an interrupt. With the exception of Start Condition WakeUp, which is asynchronously detected when the Functional clock is turned-off, all the other WakeUp events require the Functional (System) clock to be enabled.

Table 22-16. I2C_WE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-15	RESERVED	R	0h	
14	XDR_WE	R/W	0h	Transmit draining wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode, the TX FIFO level is below the threshold and the amount of data left to be transferred is less than TXTRSH value. This allows for the module to inform the CPU that it can check the amount of data to be written to the FIFO. 0h = Transmit draining wakeup disabled 1h = Transmit draining wakeup enabled
13	RDR_WE	R/W	0h	Receive draining wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C is in idle mode, configured as a receiver, and it has detected a stop condition on the bus but the RX FIFO threshold is not reached (but the FIFO is not empty). This allows for the module to inform the CPU that it can check the amount of data to be transferred from the FIFO. 0h = Receive draining wakeup disabled 1h = Receive draining wakeup enabled
12	RESERVED	R	0h	
11	ROVR_WE	R/W	0h	Receive overrun wakeup enable 0h = Receive overrun wakeup disabled 1h = Receive overrun wakeup enabled
10	XUDF_WE	R/W	0h	Transmit underflow wakeup enable 0h = Transmit underflow wakeup disabled 1h = Transmit underflow wakeup enabled

Table 22-16. I2C_WE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	AAS_WE	R/W	0h	Address as slave IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode, and external master addresses the I2C module as a slave. This allows for the module to inform the CPU that it can check which of the own addresses was used by the external master to access the I2C core. 0h = Addressed as slave wakeup disabled 1h = Addressed as slave wakeup enabled
8	BF_WE	R/W	0h	Bus free IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode and the I2C bus became free. This allows for the module to inform the CPU that it can initiate its own transfer on the I2C line. 0h = Bus Free wakeup disabled 1h = Bus Free wakeup enabled
7	RESERVED	R	0h	
6	STC_WE	R/W	0h	Start condition IRQ wakeup set. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode (with the functional clock inactive) and a possible start condition is detected on the I2C line. The STC WakeUp is generated only if the I2C_SYSC.ClockActivity field indicates that the functional clock can be disabled. Note that if the functional clock is not active, the start condition is asynchronously detected (no filtering and synchronization is used). For this reason, it is possible that the signalized start condition to be a glitch. If the functional clock cannot be disabled (I2C_SYSC.ClockActivity = 10 or 11), the programmer should not enable this wakeup, since the module has other synchronously detected WakeUp event that might be used to exit from idle mode, only if the detected transfer is accessing the I2C module. 0h = Start condition wakeup disabled 1h = Start condition wakeup enabled
5	GC_WE	R/W	0h	General call IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is in idle mode and a general call is received on I2C line. 0h = General call wakeup disabled 1h = General call wakeup enabled
4	RESERVED	R	0h	
3	DRDY_WE	R/W	0h	Receive/Transmit data ready IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is involved into a long transfer and no more registers accesses are performed on the interface (for example module are set in F/S I2C master transmitter mode and FIFO is full). If in the middle of such a transaction, the FIFO buffer needs more data to be transferred, CPU must be informed to write (in case of transmitter mode) or read (if receiver mode) in/from the FIFO. 0h = Transmit/receive data ready wakeup disabled 1h = Transmit/receive data ready wakeup enabled
2	ARDY_WE	R/W	0h	Register access ready IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is involved into a long transfer and no more registers accesses are performed on the interface (for example the module is set in F/S I2C master transmitter mode and FIFO is full). If the current transaction is finished, the module needs to inform CPU about transmission completion. 0h = Register access ready wakeup disabled 1h = Register access ready wakeup enabled

Table 22-16. I2C_WE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	NACK_WE	R/W	0h	No acknowledgment IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is involved into a long transfer and no more registers accesses are performed on the interface (for example the module is set in F/S I2C master transmitter mode and FIFO is full). If in the middle of such of a transaction a Not Acknowledgment event is raised, the module needs to inform CPU about transmission error. 0h = Not Acknowledge wakeup disabled 1h = Not Acknowledge wakeup enabled
0	AL_WE	R/W	0h	Arbitration lost IRQ wakeup enable. This read/write bit is used to enable or disable wakeup signal generation when I2C module is configured as a master and it loses the arbitration. This wake up is very useful when the module is configured as a master transmitter, all the necessary data is provided in the FIFO Tx, STT is enabled and the module enters in Idle Mode. If the module loses the arbitration, an Arbitration Lost event is raised and the module needs to inform CPU about transmission error. Note: The AL wakeup must be enabled only for multimaster communication. If the AL_WE is not enabled and the scenario described above occurs, the module will not be able to inform the CPU about the state of the transfer and it will be blocked in an undetermined state. 0h = Arbitration lost wakeup disabled 1h = Arbitration lost wakeup enabled

22.4.1.9 I2C_DMARXEN_SET Register (Offset = 38h) [reset = 0h]

I2C_DMARXEN_SET is shown in Figure 22-24 and described in Table 22-17.

Return to Summary Table.

The 1-bit field enables a receive DMA request. Writing a 1 to this field will set it to 1. Writing a 0 will have no effect, that is, the register value is not modified. Note that the I2C_BUF.RDMA_EN field is the global (slave) DMA enabler, and that it is disabled by default. The I2C_BUF.RDMA_EN field should also be set to 1 to enable a receive DMA request.

22.4.1.14 I2C_DMATXWAKE_EN Register (Offset = 4Ch) [reset = 0h]

I2C_DMATXWAKE_EN is shown in Figure 22-29 and described in Table 22-22.

Return to Summary Table.

All 1-bit fields enable a specific (synchronous) DMA request source to generate an asynchronous wakeup (on the appropriate swakeup line). Note that the I2C_SYSC.ENAWAKEUP field is the global (slave) wakeup enabler, and that it is disabled by default.

Table 22-23. I2C_SYSS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	RESERVED	R	0h	
0	RDONE	R/W	0h	Reset done bit. This read-only bit indicates the state of the reset in case of hardware reset, global software reset (I2C_SYSC.SRST) or partial software reset (I2C_CON.I2C_EN). The module must receive all its clocks before it can grant a reset-completed status. Value after reset is low. 0h = Internal module reset in ongoing 1h = Reset completed

22.4.1.16 I2C_BUF Register (Offset = 94h) [reset = 0h]

I2C_BUF is shown in Figure 22-31 and described in Table 22-24.

Return to Summary Table.

This read/write register enables DMA transfers and allows the configuration of FIFO thresholds for the FIFO management (see the FIFO Management subsection).

Figure 22-31. I2C_BUF Register

Table 22-24. I2C_BUF Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15	RDMA_EN	R/W	0h	Receive DMA channel enable. When this bit is set to 1, the receive DMA channel is enabled and the receive data ready status bit (I2C_IRQSTATUS_RAW: RRDY) is forced to 0 by the core. Value after reset is low. 0h = Receive DMA channel disabled 1h = Receive DMA channel enabled
14	RXFIFO_CLR	R/W	0h	Receive FIFO clear. When set, receive FIFO is cleared (hardware reset for RX FIFO generated). This bit is automatically reset by the hardware. During reads, it always returns 0. Value after reset is low. 0h = Normal mode 1h = Rx FIFO is reset
13-8	RXTRSH	R/W	0h	Threshold value for FIFO buffer in RX mode. The receive threshold value is used to specify the trigger level for data receive transfers. The value is specified from the Interface/OCP point of view. Value after reset is 00h. For the FIFO management description, see the FIFO Management subsection. Note 1: programmed threshold cannot exceed the actual depth of the FIFO. Note 2: the threshold must not be changed while a transfer is in progress (after STT was configured or after the module was addressed as a slave). 0h = Receive Threshold value = 64 0h = Receive Threshold value = 1 1h = Receive Threshold value = 2

Table 22-24. I2C_BUF Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	XDMA_EN	R/W	0h	Transmit DMA channel enable. When this bit is set to 1, the transmit DMA channel is enabled and the transmit data ready status (I2C_IRQSTATUS_RAW: XRDY) bit is forced to 0 by the core. Value after reset is low. 0h = Transmit DMA channel disabled 1h = Transmit DMA channel enabled
6	TXFIFO_CLR	R/W	0h	Transmit FIFO clear. When set, transmit FIFO is cleared (hardware reset for TX FIFO). This bit is automatically reset by the hardware. During reads, it always returns 0. Value after reset is low. 0h = Normal mode 1h = Tx FIFO is reset
5-0	TXTRSH	R/W	0h	Threshold value for FIFO buffer in TX mode. The Transmit Threshold value is used to specify the trigger level for data transfers. The value is specified from the OCP point of view. Value after reset is 00h Note 1: programmed threshold cannot exceed the actual depth of the FIFO. Note 2: the threshold must not be changed while a transfer is in progress (after STT was configured or after the module was addressed as a slave). 0h = Transmit Threshold value = 64 0h = Transmit Threshold value = 1 1h = Transmit Threshold value = 2

22.4.1.17 I2C_CNT Register (Offset = 98h) [reset = 0h]

I2C_CNT is shown in Figure 22-32 and described in Table 22-25.

Return to Summary Table.

CAUTION: During an active transfer phase (between STT having been set to 1 and reception of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior. This read/write register is used to control the numbers of bytes in the I2C data payload.

Figure 22-32. I2C_CNT Register

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td colspan="16">RESERVED</td><td colspan="16">DCOUNT</td></tr>
<tr><td colspan="16">R-0h</td><td colspan="16">R/W-0h</td></tr>
</table>

Table 22-25. I2C_CNT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-0	DCOUNT	R/W	0h	Data count. I2C Master Mode only (receive or transmit F/S). This 16-bit countdown counter decrements by 1 for every byte received or sent through the I2C interface. A write initializes DCOUNT to a saved initial value. A read returns the number of bytes that are yet to be received or sent. A read into DCOUNT returns the initial value only before a start condition and after a stop condition. When DCOUNT reaches 0, the core generates a stop condition if a stop condition was specified (I2C_CON.STP = 1) and the ARDY status flag is set to 1 in the I2C_IRQSTATUS_RAW register. Note that DCOUNT must not be reconfigured after I2C_CON.STT was enabled and before ARDY is received. Note 1: In case of I2C mode of operation, if I2C_CON.STP = 0, then the I2C asserts SCL = 0 when DCOUNT reaches 0. The CPU can then reprogram DCOUNT to a new value and resume sending or receiving data with a new start condition (restart). This process repeats until the CPU sets to 1 the I2C_CON.STP bit. The ARDY flag is set each time DCOUNT reaches 0 and DCOUNT is reloaded to its initial value. Values after reset are low (all 16 bits). Note 2: Since for DCOUNT = 0, the transfer length is 65536, the module does not allow the possibility to initiate zero data bytes transfers. 0h = Data counter = 65535 bytes (216 - 1) 0h = Data counter = 65536 bytes (216) 1h = Data counter = 1 bytes

22.4.1.18 I2C_DATA Register (Offset = 9Ch) [reset = 0h]

I2C_DATA is shown in Figure 22-33 and described in Table 22-26.

Return to Summary Table.

This register is the entry point for the local host to read data from or write data to the FIFO buffer.

Figure 22-33. I2C_DATA Register

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>

<tr><td colspan="24">R-0h</td><td colspan="8">R/W-0h</td></tr>
</table>

Table 22-26. I2C_DATA Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	DATA	R/W	0h	Transmit/Receive data FIFO endpoint. When read, this register contains the received I2C data. When written, this register contains the byte value to transmit over the I2C data. In SYSTEST loop back mode (I2C_SYSTEST: TMODE = 11), this register is also the entry/receive point for the data. Values after reset are unknown (all 8-bits). Note: A read access, when the buffer is empty, returns the previous read data value. A write access, when the buffer is full, is ignored. In both events, the FIFO pointers are not updated and an Access Error (AERR) Interrupt is generated.

22.4.1.19 I2C_CON Register (Offset = A4h) [reset = 0h]

I2C_CON is shown in Figure 22-34 and described in Table 22-27.

Return to Summary Table.

During an active transfer phase (between STT having been set to 1 and reception of ARDY), no modification must be done in this register (except STP enable). Changing it may result in an unpredictable behavior.

Table 22-27. I2C_CON Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15	I2C_EN	R/W	0h	I2C module enable. When this bit is cleared to 0, the I2C controller is not enabled and reset. When 0, receive and transmit FIFOs are cleared and all status bits are set to their default values. All configuration registers (I2C_IRQENABLE_SET, I2C_IRQWAKE_SET, I2C_BUF, I2C_CNT, I2C_CON, I2C_OA, I2C_SA, I2C_PSC, I2C_SCLL and I2C_SCLH) are not reset, they keep their initial values and can be accessed. The CPU must set this bit to 1 for normal operation. Value after reset is low. 0h = Controller in reset. FIFO are cleared and status bits are set to their default value. 1h = Module enabled
14	RESERVED	R	0h	
13-12	OPMODE	R/W	0h	Operation mode selection. These two bits select module operation mode. Value after reset is 00. 0h = I2C Fast/Standard mode 1h = Reserved 2h = Reserved 3h = Reserved
11	STB	R/W	0h	Start byte mode (I2C master mode only). The start byte mode bit is set to 1 by the CPU to configure the I2C in start byte mode (I2C_SA = 0000 0001). See the Philips I2C spec for more details. Value after reset is low. 0h = Normal mode 1h = Start byte mode

Table 22-27. I2C_CON Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10	MST	R/W	0h	Master/slave mode (I2C mode only). When this bit is cleared, the I2C controller is in the slave mode and the serial clock (SCL) is received from the master device. When this bit is set, the I2C controller is in the master mode and generates the serial clock. Note: This bit is automatically cleared at the end of the transfer on a detected stop condition, in case of arbitration lost or when the module is configured as a master but addressed as a slave by an external master. Value after reset is low. 0h = Slave mode 1h = Master mode
9	TRX	R/W	0h	Transmitter/receiver mode (i2C master mode only). When this bit is cleared, the I2C controller is in the receiver mode and data on data line SDA is shifted into the receiver FIFO and can be read from I2C_DATA register. When this bit is set, the I2C controller is in the transmitter mode and the data written in the transmitter FIFO via I2C_DATA is shifted out on data line SDA. Value after reset is low. The operating modes are defined as follows: MST = 0, TRX = x, Operating Mode = Slave receiver. MST = 0, TRX = x, Operating Mode = Slave transmitter. MST = 1, TRX = 0, Operating Modes = Master receiver. MST = 1, TRX = 0, Operating Modes = Master transmitter. 0h = Receiver mode 1h = Transmitter mode
8	XSA	R/W	0h	Expand slave address. (I2C mode only). When set, this bit expands the slave address to 10-bit. Value after reset is low. 0h = 7-bit address mode 1h = 10-bit address mode
7	XOA0	R/W	0h	Expand own address 0. (I2C mode only). When set, this bit expands the base own address (OA0) to 10-bit. Value after reset is low. 0h = 7-bit address mode 1h = 10-bit address mode
6	XOA1	R/W	0h	Expand own address 1. (I2C mode only). When set, this bit expands the first alternative own address (OA1) to 10-bit. Value after reset is low. 0h = 7-bit address mode 1h = 10-bit address mode
5	XOA2	R/W	0h	Expand own address 2. (I2C mode only). When set, this bit expands the second alternative own address (OA2) to 10-bit. Value after reset is low. 0h = 7-bit address mode. (I2C mode only). 1h = 10-bit address mode
4	XOA3	R/W	0h	Expand own address 3. When set, this bit expands the third alternative own address (OA3) to 10-bit. Value after reset is low. 0h = 7-bit address mode 1h = 10-bit address mode

Table 22-27. I2C_CON Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3-2	RESERVED	R	0h	
1	STP	R/W	0h	Stop condition (I2C master mode only). This bit can be set to a 1 by the CPU to generate a stop condition. It is reset to 0 by the hardware after the stop condition has been generated. The stop condition is generated when DCOUNT passes 0. When this bit is not set to 1 before the end of the transfer (DCOUNT = 0), the stop condition is not generated and the SCL line is hold to 0 by the master, which can re-start a new transfer by setting the STT bit to 1. Value after reset is low 0h = No action or stop condition detected 1h = Stop condition queried
0	STT	R/W	0h	Start condition (I2C master mode only). This bit can be set to a 1 by the CPU to generate a start condition. It is reset to 0 by the hardware after the start condition has been generated. The start/stop bits can be configured to generate different transfer formats. Value after reset is low. Note: DCOUNT is data count value in I2C_CNT register. STT = 1, STP = 0, Conditions = Start, Bus Activities = S-A-D. STT = 0, STP = 1, Conditions = Stop, Bus Activities = P. STT = 1, STP = 1, Conditions = Start-Stop (DCOUNT=n), Bus Activities = S-A-D..(n)..D-P. STT = 1, STP = 0, Conditions = Start (DCOUNT=n), Bus Activities = S-A-D..(n)..D. 0h = No action or start condition detected 1h = Start condition queried

22.4.1.20 I2C_OA Register (Offset = A8h) [reset = 0h]

I2C_OA is shown in Figure 22-35 and described in Table 22-28.

Return to Summary Table.

CAUTION: During an active transfer phase (between STT having been set to 1 and reception of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior. This register is used to specify the module s base I2C 7-bit or 10-bit address (base own address).

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	
9-0	SA	R/W	0h	Slave address. This field specifies either: A 10-bit address coded on SA [9:0] when XSA (Expand Slave Address, I2C_CON[8]) is set to 1. or A 7-bit address coded on SA [6:0] when XSA (Expand Slave Address, I2C_CON[8]) is cleared to 0. In this case, SA [9:7] bits must be cleared to 000 by application software. Value after reset is low (all 10 bits).

22.4.1.22 I2C_PSC Register (Offset = B0h) [reset = 0h]

I2C_PSC is shown in Figure 22-37 and described in Table 22-30.

Return to Summary Table.

CAUTION: During an active mode (I2C_EN bit in I2C_CON register is set to 1), no modification must be done in this register. Changing it may result in an unpredictable behavior. This register is used to specify the internal clocking of the I2C peripheral core.

Figure 22-37. I2C_PSC Register

31-8	7-0
RESERVED	PSC
R-0h	R/W-0h

Table 22-30. I2C_PSC Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	PSC	R/W	0h	Fast/Standard mode prescale sampling clock divider value. The core uses this 8-bit value to divide the system clock (SCLK) and generates its own internal sampling clock (ICLK) for Fast and Standard operation modes. The core logic is sampled at the clock rate of the system clock for the module divided by (PSC + 1). Value after reset is low (all 8 bits). 0h (R/W) = Divide by 1 1h (R/W) = Divide by 2 FFh (R/W) = Divide by 256

22.4.1.23 I2C_SCLL Register (Offset = B4h) [reset = 0h]

I2C_SCLL is shown in Figure 22-38 and described in Table 22-31.

Return to Summary Table.

CAUTION: During an active mode (I2C_EN bit in I2C_CON register is set to 1), no modification must be done in this register. Changing it may result in an unpredictable behavior. This register is used to determine the SCL low time value when master.

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	SCLL	R/W	0h	Fast/Standard mode SCL low time. I2C master mode only, (FS). This 8-bit value is used to generate the SCL low time value (tLOW) when the peripheral is operated in master mode. tLOW = (SCLL + 7) * ICLK time period, Value after reset is low (all 8 bits).

22.4.1.24 I2C_SCLH Register (Offset = B8h) [reset = 0h]

I2C_SCLH is shown in Figure 22-39 and described in Table 22-32.

Return to Summary Table.

CAUTION: During an active mode (I2C_EN bit in I2C_CON register is set to 1), no modification must be done in this register. Changing it may result in an unpredictable behavior. This register is used to determine the SCL high time value when master.

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	SCLH	R/W	0h	Fast/Standard mode SCL low time. I2C master mode only, (FS). This 8-bit value is used to generate the SCL high time value (tHIGH) when the peripheral is operated in master mode. - tHIGH = (SCLH + 5) * ICLK time period. Value after reset is low (all 8 bits).

22.4.1.25 I2C_SYSTEST Register (Offset = BCh) [reset = 0h]

I2C_SYSTEST is shown in Figure 22-40 and described in Table 22-33.

Return to Summary Table.

CAUTION: Never enable this register for normal I2C operation This register is used to facilitate system-level tests by overriding some of the standard functional features of the peripheral. It allows testing of SCL counters, controlling the signals that connect to I/O pins, or creating digital loop-back for self-test when the module is configured in system test (SYSTEST) mode. It also provides stop/non-stop functionality in the debug mode.

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15	ST_EN	R/W	0h	System test enable. This bit must be set to 1 to permit other system test registers bits to be set. Value after reset is low. 0h (R/W) = Normal mode. All others bits in register are read only. 1h (R/W) = System test enabled. Permit other system test registers bits to be set.

Table 22-33. I2C_SYSTEST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	FREE	R/W	0h	Free running mode (on breakpoint). This bit is used to determine the state of the I2C controller when a breakpoint is encountered in the HLL debugger. Note: This bit can be set independently of ST_EN value. FREE = 0: the I2C controller stops immediately after completion of the on-going bit transfer. Stopping the transfer is achieved by forcing the SCL line low. Note that in this case there will be no status register updates. FREE = 1: the I2C interface runs free. When Suspend indication will be asserted, there will be no accesses on the OCP Interface (the CPU is in debug mode) and consequently the FIFOs will reach full/empty state (according to RX or TX modes) and the I2C SDA line will be kept low. Note that the status registers will be updated, but no DMA, IRQ or WakeUp will be generated. The status registers likely to be updated in this mode are: I2C_IRQSTATUS_RAW.XRDY, I2C_IRQSTATUS_RAW.RRDY, I2C_IRQSTATUS_RAW.XUDF, I2C_IRQSTATUS_RAW.ROVR, I2C_IRQSTATUS_RAW.ARDY and I2C_IRQSTATUS_RAW.NACK. Value after reset is low. 0h (R/W) = Stop mode (on breakpoint condition). If Master mode, it stops after completion of the on-going bit transfer. In slave mode, it stops during the phase transfer when 1 byte is completely transmitted/received. 1h (R/W) = Free running mode
13-12	TMODE	R/W	0h	Test mode select. In normal functional mode (ST_EN = 0), these bits are don't care. They are always read as 00 and a write is ignored. In system test mode (ST_EN = 1), these bits can be set according to the following table to permit various system tests. Values after reset are low (2 bits). SCL counter test mode: in this mode, the SCL pin is driven with a permanent clock as if mastered with the parameters set in the I2C_PSC, I2C_SCLL, and I2C_SCLH registers. Loop back mode: in the master transmit mode only, data transmitted out of the I2C_DATA register (write action) is received in the same I2C_DATA register via an internal path through the FIFO buffer. The DMA and interrupt requests are normally generated if enabled. SDA/SCL IO mode: in this mode, the SCL IO and SDA IO are controlled via the I2C_SYSTEST [5:0] register bits. 0h (R/W) = Functional mode (default) 1h = Reserved 2h (R/W) = Test of SCL counters (SCLL, SCLH, PSC). SCL provides a permanent clock with master mode. 3h (R/W) = Loop back mode select + SDA/SCL IO mode select
11	SSB	R/W	0h	Set status bits. Writing 1 into this bit also sets the 6 read/clear-only status bits contained in I2C_IRQSTATUS_RAW register (bits 5:0) to 1. Writing 0 into this bit doesn't clear status bits that are already set only writing 1 into a set status bit can clear it (see I2C_IRQSTATUS_RAW operation). This bit must be cleared prior attempting to clear a status bit. Value after reset is low. 0h (R/W) = No action. 1h (R/W) = Set all interrupt status bits to 1.
10-9	RESERVED	R	0h	

Table 22-33. I2C_SYSTEST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	SCL_I_FUNC	R	0h	SCL line input value (functional mode). This read-only bit returns the logical state taken by the SCL line (either 1 or 0). It is active both in functional and test mode. Value after reset is low. 0h (R) = Read 0 from SCL line 1h (R) = Read 1 from SCL line
7	SCL_O_FUNC	R	0h	SCL line output value (functional mode). This read-only bit returns the value driven by the module on the SCL line (either 1 or 0). It is active both in functional and test mode. Value after reset is low. 0h (R) = Driven 0 on SCL line 1h (R) = Driven 1 on SCL line
6	SDA_I_FUNC	R	0h	SDA line input value (functional mode). This read-only bit returns the logical state taken by the SDA line (either 1 or 0). It is active both in functional and test mode. Value after reset is low. 0h (R) = Read 0 from SDA line 1h (R) = Read 1 from SDA line
5	SDA_O_FUNC	R	0h	SDA line output value (functional mode). This read-only bit returns the value driven by the module on the SDA line (either 1 or 0). It is active both in functional and test mode. Value after reset is low. 0h (R) = Driven 0 to SDA line 1h (R) = Driven 1 to SDA line
4	RESERVED	R	0h	
3	SCL_I	R	0h	SCL line sense input value. In normal functional mode (ST_EN = 0), this read-only bit always reads 0. In system test mode (ST_EN = 1 and TMODE = 11), this read-only bit returns the logical state taken by the SCL line (either 1 or 0). Value after reset is low. 0h (R) = Read 0 from SCL line 1h (R) = Read 1 from SCL line
2	SCL_O	R	0h	SCL line drive output value. In normal functional mode (ST_EN = 0), this bit is don't care. It always reads 0 and a write is ignored. In system test mode (ST_EN = 1 and TMODE = 11), a 0 forces a low level on the SCL line and a 1 puts the I2C output driver to a high-impedance state. Value after reset is low. 0h = Forces 0 on the SCL data line 1h (R) = SCL output driver in high-impedance state
1	SDA_I	R	0h	SDA line sense input value. In normal functional mode (ST_EN = 0), this read-only bit always reads 0. In system test mode (ST_EN = 1 and TMODE = 11), this read-only bit returns the logical state taken by the SDA line (either 1 or 0). Value after reset is low. 0h (R) = Read 0 from SDA line 1h (R) = Read 1 from SDA line

Table 22-33. I2C_SYSTEST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	SDA_O	R	0h	SDA line drive output value. In normal functional mode (ST_EN = 0), this bit is don't care. It reads as 0 and a write is ignored. In system test mode (ST_EN = 1 and TMODE = 11), a 0 forces a low level on the SDA line and a 1 puts the I2C output driver to a high-impedance state. Value after reset is low. 0h (W) = Write 0 to SDA line 1h (W) = Write 1 to SDA line

22.4.1.26 I2C_BUFSTAT Register (Offset = C0h) [reset = 0h]

I2C_BUFSTAT is shown in Figure 22-41 and described in Table 22-34.

Return to Summary Table.

This read-only register reflects the status of the internal buffers for the FIFO management (see the FIFO Management subsection).

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-14	FIFODEPTH	R	0h	Internal FIFO buffers depth. This read-only bit indicates the internal FIFO buffer depth. Value after reset is given by the boundary module generic parameter. 0h = 8-bytes FIFO 1h = 16-bytes FIFO 2h = 32-bytes FIFO 3h = 64-bytes FIFO
13-8	RXSTAT	R	0h	RX buffer status. This read-only field indicates the number of bytes to be transferred from the FIFO at the end of the I2C transfer (when RDR is asserted). It corresponds to the level indication of the RX FIFO (number of written locations). Value after reset is 0.
7-6	RESERVED	R	0h	
5-0	TXSTAT	R	0h	TX buffer status. This read-only field indicates the number of data bytes still left to be written in the TX FIFO (it s equal with the initial value of I2C_CNT.DCOUNT minus the number of data bytes already written in the TX FIFO through the OCP Interface). Value after reset is equal with 0.

22.4.1.27 I2C_OA1 Register (Offset = C4h) [reset = 0h]

I2C_OA1 is shown in Figure 22-42 and described in Table 22-35.

Return to Summary Table.

CAUTION: During an active transfer phase (between STT has been set to 1 and receiving of ARDY), no modification must be done in this register. Changing it may result in an unpredictable behavior. This register is used to specify the first alternative I2C 7-bit or 10-bit address (own address 1 - OA1).

HDQ/1-Wire Interface

This chapter describes the HDQ/1-wire interface of the device.

Topic **Page**

23.1 Introduction

23.1.1 HDQ1W Features

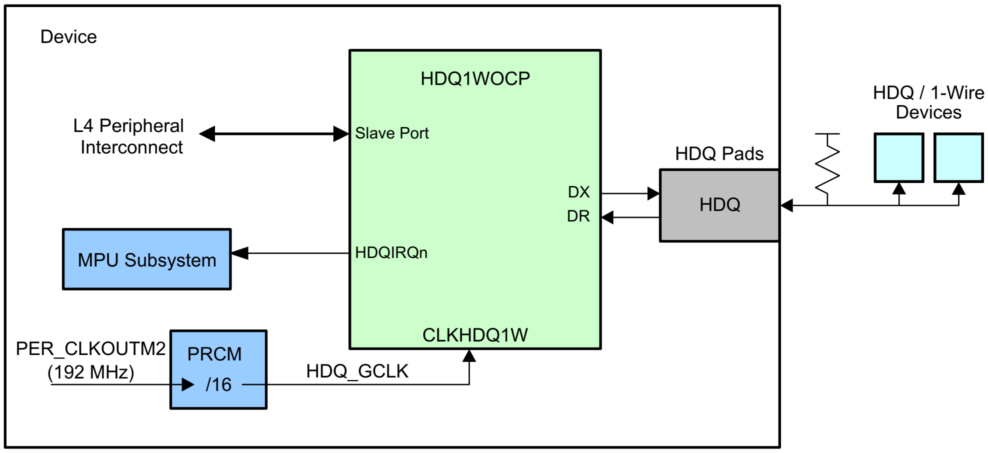
The main features of the HDQ1W include:

- Software selectable HDQ or 1-Wire mode
- 1-Wire single-bit mode
- Return-to-one accomplished via external pull-up
- Timeout monitor
- Interrupt to indicate Tx/Rx completion or timeout

23.2 Integration

The HDQ / 1-Wire module (HDQ1W) implements the hardware protocol of a Benchmarq HDQ and Dallas Semiconductor (Maxim) 1-Wire® master function.

Figure 23-1. HDQ1W Integration



23.2.1 *HDQ1W Connectivity Attributes*

The general connectivity attributes for the HDQ1W module are shown in Table 23-1.

Table 23-1. HDQ1W Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	L4PER_L4LS_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart idle
Interrupt Requests	1 interrupt to MPU Subsystem (HDQINT)
DMA Requests	None
Physical Address	L4 peripheral slave port

23.2.2 *HDQ1W Clock and Reset Management*

The HDQ1W has an OCP clock and a separate functional clock.

Table 23-2. HDQ1W Clock Signals

Clock Signal	Maximum Frequency	Reference Source	Comments
CLK Interface / functional clock	100 MHz	CORE_CLKOUTM4 / 2	l4per_l4ls_gclk from PRCM
CLKHDQ1S Functional clock	12 MHz	PER_CLKOUTM2 / 16	pd_per_hdq_gclk from PRCM

23.2.3 *HDQ1W Pin List*

The HDQ1W interface uses a single wire for command and data as summarized in Table 23-3. The signal is implemented as oped-drain and requires an external pulllup for return-to-one when not being driven by the master or slave device.

Table 23-3. HDQ1W Pin List

Pin	Type	Description
HDQ	I/O	HDQ / 1-Wire command/data wire

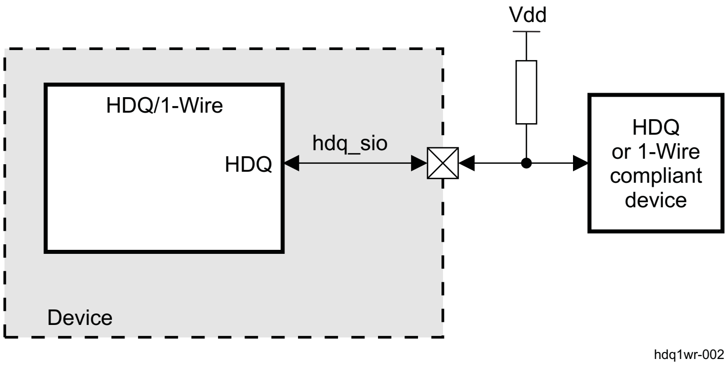
23.3 Functional Description

The HDQ/1-Wire module works with both the HDQ and 1-Wire protocols. The protocols use a single wire to establish communication between the master and the slave. Both protocols use a return-to-1 mechanism; that is, after any command is driven, the line is pulled to a high level. This mechanism requires an external pullup.

23.3.1 HDQ/1-Wire Functional Interface

Figure 23-2 shows a typical application using the HDQ/1-Wire connection.

Figure 23-2. HDQ/1-Wire Typical Application System Overview



An external pullup is required, because the two protocols use a return-to-1 mechanism (that is, logical '1' level is applied by a pullup after any drive-to-zero by a HDQ/1-Wire master or slave). Pullup is typically implemented as a resistor connected between HDQ/1-Wire line and the I/O power supply.

The HDQ/1-Wire module operates according to a command structure that is programmed into transmit command registers (as described in Section 23.4).

The 1-Wire mode runs at slower speeds than the capabilities of the mode.

Table 23-4 describes the external signal for connection with HDQ or 1-Wire compliant devices.

Table 23-4. I/O Description

Signal Name	I/O	Description	Value at Reset
hdq_sio	Bidir	Serial data input/output. Output is open drain type.	0

23.3.2 HDQ and 1-Wire (SDQ) Protocols

23.3.2.1 HDQ Protocol Initialization (Default)

In HDQ mode, the firmware does not require the host to create an initialization pulse to the slave. However, the slave can be reset by using an initialization pulse (also referred to as a break pulse). The initialization pulse is generated by setting the INITIALIZATION bit (HDQ1W_CTRL_STS[2]). The slave does not respond with a presence pulse as it does in the 1-Wire protocol.

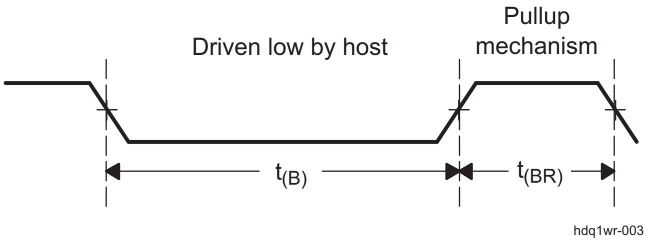
The HDQ is a command-based protocol in which the host sends a command byte to the slave. The command directs the slave either to store the next eight bits of data received to a register specified by the command byte (write operation) or to output the eight bits of data from a register specified by the command byte (read operation). The master implementation is a simple byte engine. The sending of the ID, command/address, and data is controlled by firmware. The master engine provides only a single HDQ1W_TX_DATA register.

The command and data bytes consist of a stream of eight bits with a maximum transmission rate of 5K bits/s. The least significant bit (LSB) of a command or data byte is transmitted first. If a communication time-out occurs between the host and the slave (for example, if the host waits longer than the specified time for the slave to respond, or if this is the first access command), then the host must send an initialization pulse (BREAK pulse) before sending the command again.

The slave detects a break when the HDQ pin is driven to a logic-low state for a specified break time t(B) or greater. The HDQ pin then returns to its normal ready-high logic state for a specified break-recovery time t(BR). The slave is then ready for a command from the host processor. Figure 23-3 shows this behavior.

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition. Reading the interrupt status register clears all interrupt conditions. Only one interrupt signal is sent to the microcontroller, and only one overall mask bit can enable or disable the interrupt. The interrupt conditions cannot be individually masked.

Figure 23-3. HDQ Break-Pulse Timing Diagram

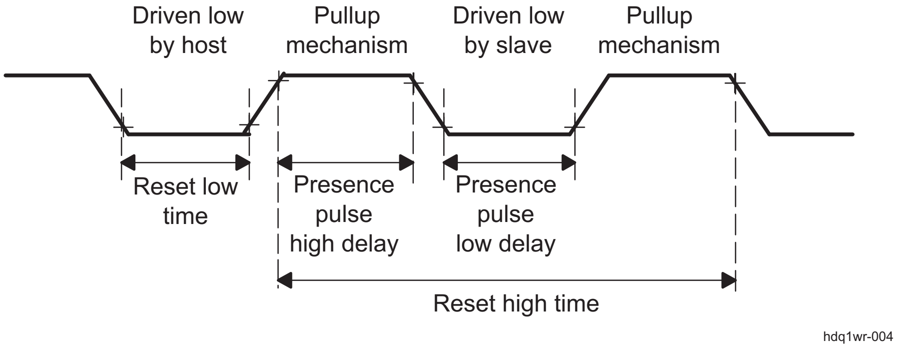


23.3.2.2 1-Wire (SDQ) Protocol Initialization

In 1-Wire (SDQ) protocol, the host first sends an initialization pulse (by pulling the line to a logic-low state) and then waits for the slave to respond with a presence pulse before enabling any communication sequence.

As for the initialization pulse, the presence pulse is a low-going edge on the line initiated by the slave. The timing diagram in Figure 23-4 shows the 1-Wire (SDQ) reset sequence.

Figure 23-4. 1-Wire (SDQ) Reset Timing Diagram



The host drives the line to a logic-low state for a minimum of reset low time. Once the slave detects this pulse, it must drive the line to a logic-low state within the presence pulse high delay for a minimum period of presence pulse low time.

If the slave does not respond within this interval of time, a time-out event occurs and no transaction can be initiated. The host must initiate the reset sequence again before sending any command to the slave.

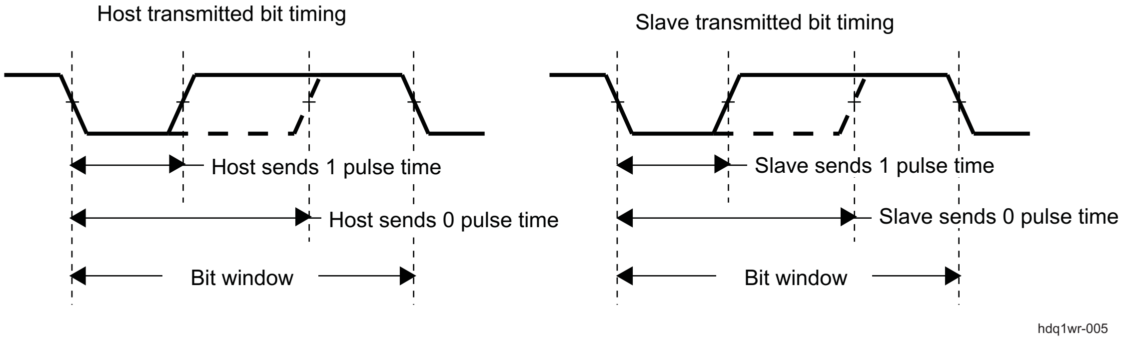
On the other hand, if the slave sends back its presence pulse within the specified interval of time, the communication can be enabled after the reset high time.

23.3.2.3 Communication Sequence (HDQ and 1-Wire Protocols)

This section describes the part common to both protocols.

After a successful break pulse (HDQ mode) or initialization sequence (1-Wire protocol), the host and slave are ready for bit transmission. Each bit to transmit (either from the host to the slave or from the slave to the host) is preceded by a low-going edge on the line, as shown in Figure 23-5.

Figure 23-5. HDQ/1-Wire Transmitted Bit Timing



The return-to-1 data-bit frame consists of three distinct sections. The first section starts the transmission when either the slave or the host takes the line to a logic-low state. The next section is the actual data transmission in which the data must be valid during a specified period of time after the negative edge that starts the communication. The final section stops the transmission by returning the HDQ/1-Wire line to a logic-high state. Communication with an HDQ/1-Wire slave always occurs with the LSB being transmitted first.

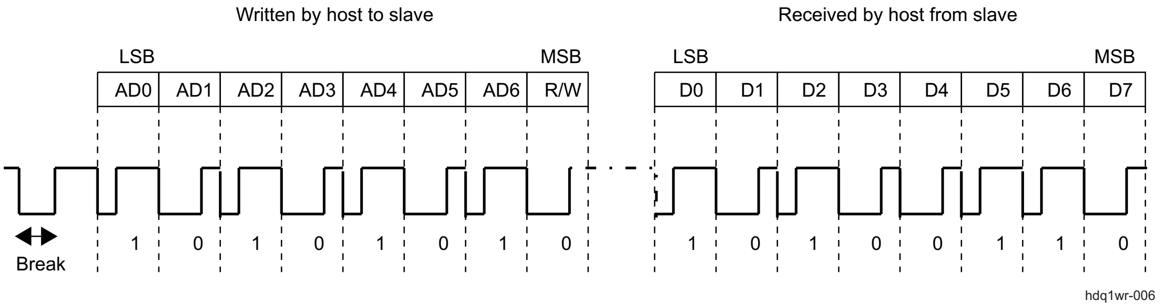
The command byte of the HDQ/1-Wire protocols consists of eight contiguous valid command bits. The command byte contains two fields: R/W command and address. The R/W bit of the command byte determines whether the command is a read or a write, and the address field containing bits AD6-AD0 indicates the address to be read or written. Table 23-5 lists the command byte values.

Table 23-5. HDQ/1-Wire Command Byte

7	6	5	4	3	2	1	0
R/W	AD6	AD5	AD4	AD3	AD2	AD1	AD0

R/W	Indicates whether the command byte is a read or a write. A 1 indicates a write command; the following eight bits must be written to the register specified by the address field of the command byte. A 0 indicates that the command is a read. On a read command, the slave outputs the requested register contents.
AD6-AD0	Represent the seven bits labeled AD6-AD0 containing the address portion of the register to be accessed. The communication sequence example in Figure 23-6 shows a read command at address 0x55; the received data is 0x65.

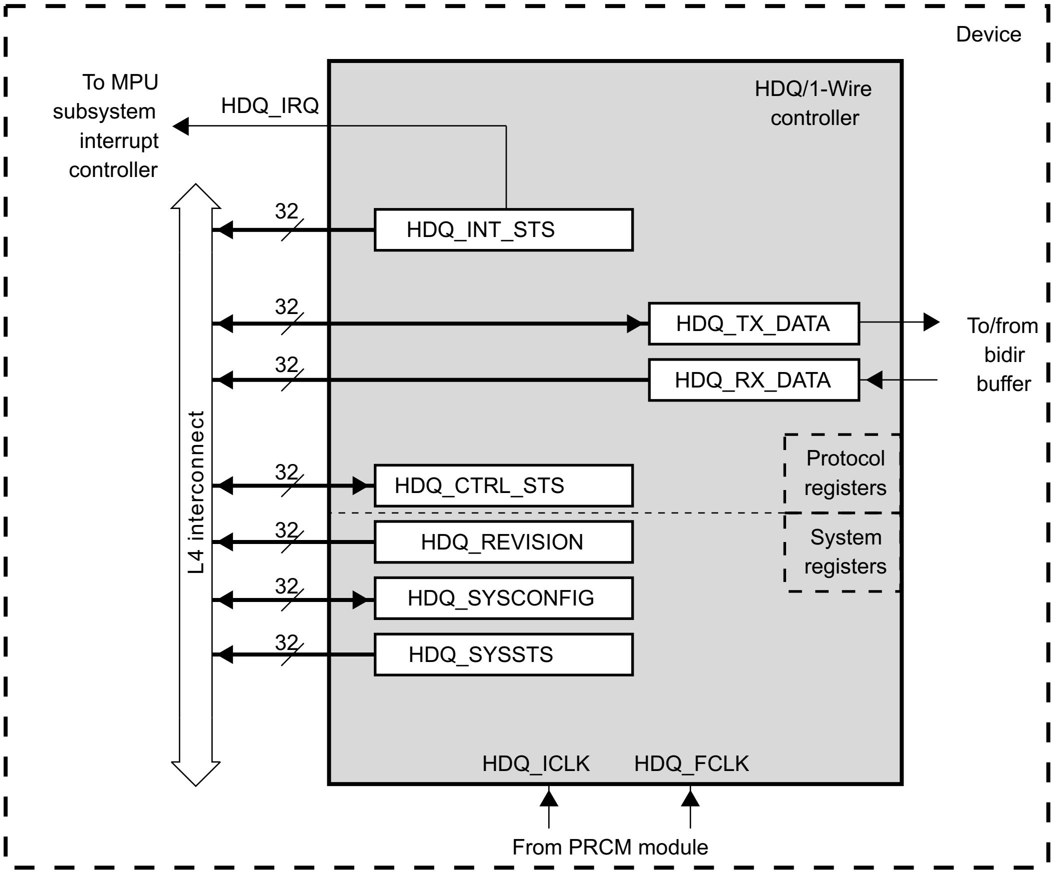
Figure 23-6. HDQ/1-Wire Communication Sequence



23.3.3 HDQ/1-Wire Block Diagram

Figure 23-7 shows the HDQ/1-Wire block diagram.

Figure 23-7. HDQ/1-Wire Block Diagram

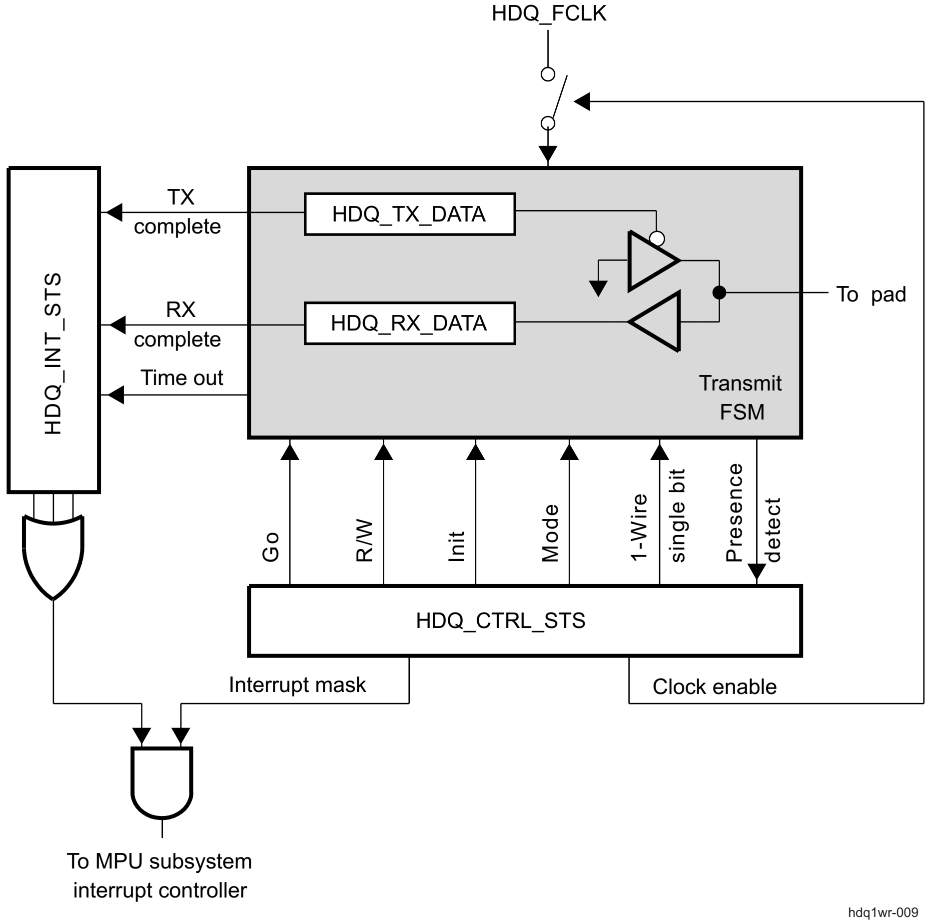


hdq1wr-008

The MODE bit HDQ1W_CTRL_STS[0] allows selection between the HDQ and 1-Wire protocols. This bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Figure 23-8 shows the protocol-dedicated register scheme.

Figure 23-8. Protocol Registers Description



The receive and transmit operations are performed with respect to the HDQ protocol timing. The module is implemented once in the device and is clocked with a single clock whether it runs HDQ or 1-Wire protocol. Although the data exchange is slower than the capabilities of the 1-Wire mode, this mode still meets the timing requirements and practical considerations. That is, the 1-Wire protocol runs at the HDQ protocol speed, which is slower (5K bits/s). The timing parameters and protocol are different in the two modes.

23.3.4 HDQ Mode (Default)

23.3.4.1 HDQ Mode Features

The HDQ mode supports the following:

- Benchmark HDQ protocol
- Power-down mode

23.3.4.2 Description

In the HDQ mode, there is no need for the host to create an initialization pulse to the slave. However, the host can reset the slave by using an initialization pulse (also known as a break pulse). Setting the INITIALIZATION bit HDQ1W_CTRL_STS[2] creates this pulse by pulling the line down. When the slave receives the pulse, it is ready for communication but does not respond with a presence pulse.

In a typical write operation, two bytes are sent to the slave. The first byte corresponds to the command/address byte, and the second byte corresponds to the data to be written.

In a typical read operation, the host sends a command/address byte and the slave returns a byte of data.

The master is implemented to send and receive bytes. Sending the command/address and data is controlled by the firmware. The master provides only a single data TX register.

The HDQ protocol is a return-to-1 protocol. Consequently, after a byte is sent to the slave (either command/address + data for a write, or just command/address for a read), the host pulls the line up. The line is set to the high-impedance state in the device and an external pullup brings it to a logical high level.

In the case of a read operation, the slave also drives the line to a logic-low state before sending the requested data.

If the host initiates a read and does not receive data within a specified interval of time (that is, the slave does not drive the line low within this interval), the TIMEOUT bit HDQ1W_INT_STS[0] is set, thereby indicating a read failure. The TIMEOUT bit remains set until the host reads the interrupt status register (HDQ1W_INT_STS).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out on a transaction. The corresponding bit is set in the interrupt status register (HDQ1W_INT_STS). This register is cleared as soon as it is read.

Only one interrupt signal is sent to the MPU, and only an overall mask can enable or disable the interrupts. These interrupts cannot be individually masked.

23.3.4.3 Single-Bit Mode

In HDQ mode, the single-bit mode (1_WIRE_SINGLE_BIT bit HDQ1W_CTRL_STS[7] set to 1) has no effect because the HDQ protocol supports only byte transfers.

23.3.4.4 Interrupt Conditions

The HDQ/1-Wire module provides the following interrupt status:

1. Transmission complete:

   A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in HDQ protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ1W_INT_STS).

2. Read complete:

   In HDQ mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ1W_INT_STS).

3. Presence detect/time-out:

   In HDQ mode, the interrupt status indicates that after a read command initiated by the host, the slave did not pull the line low within the specified time. This interrupt condition is cleared by reading the interrupt status register (HDQ1W_INT_STS).

   In HDQ mode, a time-out condition is also used to indicate the successful completion of a break pulse. That is, if the master has sent the break pulse, it is indicated with a time-out instead of a TX-complete.

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all the interrupt status bits that were previously set.

23.3.5 1-Wire Mode

23.3.5.1 1-Wire Mode Features

The 1-Wire mode supports the following:

- Dallas Semiconductor 1-Wire protocol
- Power-down mode
- Single-bit mode

23.3.5.2 Description

The 1-Wire mode requires an initialization pulse to be sent to the slave(s) connected on the interface. If a slave is present, it responds with a presence pulse.

The initialization pulse is sent after INITIALIZATION bit HDQ1W_CTRL_STS[2] is set. The firmware sends the initialization pulse depending on the value of this bit.

The slave presence on the line is detected by a presence bit in the control and status register. When the slave receives the initialization pulse, it sends back its presence pulse by pulling down the line. The module detects this low-going edge and sets the PRESENCEDETECT bit HDQ1W_CTRL_STS[3].

In a similar way, if a presence pulse is not received from the slave after an initialization pulse is sent, the PRESENCEDETECT bit remains cleared.

Whether or not a presence pulse is detected after an initialization pulse is sent, the TIMEOUT bit HDQ1W_INT_STS[0] is set and an interrupt condition is generated.

In 1-Wire mode, the generated interrupt condition means the maximum time allowed for receiving the response has elapsed and the software must check the PRESENCEDETECT bit to determine whether or not there was a presence pulse.

The INITIALIZATION bit is cleared at the end of the initialization pulse at the same time as the TIMEOUT bit is set. The TIMEOUT bit is cleared when the interrupt status register (HDQ1W_INT_STS) is read.

For read operations, 1-Wire is a bit-by-bit protocol, which means the slave must be clocked by the host for each bit of the byte to read.

The line is pulled up at the end of the command/address byte. On the first read, the host creates a low-going edge to initiate a bit read. The line is then pulled up (pulled to the high-impedance state by the host and set to a high logical level by the external pullup) and the slave either drives the line low to transmit a 0 or does not drive the line to transmit a 1. This sequence is repeated for each bit to read.

The first bit the host receives is the LSB, and the last bit is the most significant bit (MSB) in the receive data register (HDQ1W_RX_DATA).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition (that is, the time allowed for the slave to indicate its presence has elapsed). A read operation on the interrupt status register clears the interrupt conditions previously set. As in the HDQ mode, only one interrupt signal is sent to the MPU. Only an overall mask bit can enable or disable the interrupt (the interrupt conditions cannot be masked individually).

23.3.5.3 1-Wire Single-Bit Mode Operation

A single-bit mode can be entered by setting the appropriate bit in the control and status register (1_WIRE_SINGLE_BIT bit HDQ1W_CTRL_STS[7]). In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, an interrupt is generated (that is, there is an RX-complete for a read operation and a TX-complete for a write operation). Bit 0 of the RX register (HDQ1W_RX_DATA) is updated each time a bit is received from the slave; bit 0 of the TX register (HDQ1W_TX_DATA) contains the bit to be sent.

23.3.5.4 Interrupt Conditions

The HDQ/1-Wire module provides the following interrupt status:

1. Transmission complete:

   A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in 1-Wire protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ1W_INT_STS).
2. Read complete:

   In 1-Wire mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ1W_INT_STS).
3. Presence detect/time-out:

   In 1-Wire mode, the interrupt status indicates that it is now valid to check the PRESENCEDETECT bit. This interrupt condition is cleared by reading the interrupt status register (HDQ1W_INT_STS).

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all interrupt status bits that were previously set.

23.3.5.5 Status Flags

The presence-condition-detected status flag is contained in the PRESENCEDETECT bit HDQ1W_CTRL_STS[3]. This is valid only in 1-Wire mode. The flag is updated when TIMEOUT bit HDQ1W_INT_STS[0] is set. Therefore, its correct value shows only after the interrupt is generated. The firmware must wait for the time-out condition; otherwise, the flag keeps its previous value and is undefined.

23.3.6 Module Power Saving

23.3.6.1 Autoidle Mode

The HDQ/1-Wire module provides an autoidle function in its interconnect clock domain.

The interconnect clock autoidle power-saving mode is enabled or disabled through the AUTOIDLE bit HDQ1W_SYSCONFIG[0]. When this mode is enabled and there is no activity on the interconnect interface, the interconnect clock (HDQ_ICLK) is disabled inside the module, thereby reducing power consumption. When there is new activity on the interconnect interface, the interconnect clock is restarted with no latency penalty. This mode is disabled by default after a reset.

This mode is recommended to reduce power consumption.

23.3.6.2 Power-Down Mode

The HDQ/1-Wire module also provides a power-saving function in its functional clock domain.

Setting the CLOCKENABLE bit in the control and status register (CLOCKENABLE bit HDQ1W_CTRL_STS[5]) to 0 shuts off the functional clock (HDQ_FCLK) to the state-machine. The state-machine is reset when the functional clock is disabled; if any transaction is ongoing, it is aborted into the reset state.

The register values are not affected by disabling the functional clock.

Do not access the module registers after the software has put the module in power-down mode except to write to the CLOCKENABLE bit to take the module out of power-down mode.

23.3.7 System Power Management and Wakeup

As part of the system-wide power-management scheme, the HDQ/1-Wire module can go into idle state at the request of the PRCM module (for more information, see Chapter 6, *Power, Reset, and Clock Management*). However, the HDQ/1-Wire module does not support handshake protocol with the PRCM. The HDQ/1-Wire module can go into idle mode only as part of the L4 interconnect clock domain (both CORE_L4_ICLK and FUNC_12M_CLK belong to the L4 interconnect clock domain).

When the AUTO_HDQ bit PRCM.CM_AUTOIDLE1_CORE[22] is set, the HDQ/1-Wire module behavior follows the L4 interconnect clock domain behavior. If the whole domain is put into idle, the HDQ/1-Wire is also put into idle.

Software must ensure correct clock management.

CAUTION

There is no hardware mechanism to prevent cutting off the HDQ/1-Wire clocks while the module is performing a transfer. The result would be a loss of data being transferred.

23.4 Programming Model

The HDQ/1-Wire module can be considered a simple byte engine because it only implements the hardware interface layer for both HDQ and 1-Wire protocols. The correct sequencing is controlled by the firmware, which is described in this section.

23.4.1 Module Initialization Sequence

23.4.1.1 Mode Selection

MODE bit HDQ1W_CTRL_STS[0] allows selection between the HDQ and 1-Wire protocols. When set to 0, the protocol is HDQ; when set to 1, the protocol is 1-Wire. The bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Although this bit can be modified at any point, it is strongly recommended that it be modified only as part of the boot-up configuration.

23.4.1.2 Reset/Initialization

No slave presence test is required in HDQ mode; however, the slave can be reset by setting the INITIALIZATION bit HDQ1W_CTRL_STS[2] and the GO bit HDQ1W_CTRL_STS[4]. The line is then pulled down (break pulse) and the bit returns to 0 after the pulse is sent. Upon completion, a time-out interrupt is also generated. The slave does not respond to this pulse.

In 1-Wire mode, the slave returns a presence pulse when it receives the initialization pulse. The protocol for initialization is as follows:

1. Set the INITIALIZATION bit HDQ1W_CTRL_STS[2] to 1 and the GO bit HDQ1W_CTRL_STS[4] to 1 to send the pulse. When the pulse is sent, the bit is cleared in the register.
2. Wait for the presence detect flag (TIMEOUT bit HDQ1W_INT_STS[0]) to generate an interrupt. This flag is set when the response time allowed to the slave has elapsed, whether it has sent a pulse or not.
3. Read the HDQ1W_CTRL_STS register to check whether the presence pulse has been received before starting any transfer.

23.4.2 HDQ Protocol Basic Programming Model

23.4.2.1 Write Operation

The write operation sequence is as follows:

1. Write the command/address or data value to the TX write register (HDQ1W_TX_DATA).

NOTE: Steps 2 and 3 can be performed simultaneously.

2. Set DIR bit HDQ1W_CTRL_STS[1] to indicate a write.
3. Set GO bit HDQ1W_CTRL_STS[4] to start the transmission.
   a. The hardware sends the byte from the TX write register.
   b. In a write operation, the TIMEOUT bit is always cleared, because there is no acknowledge mechanism from the slave.
   c. When the write operation is completed, the TX-complete flag is set in the interrupt status register (TXCOMPLETE bit HDQ1W_INT_STS[2]). If interrupts are masked (that is, the corresponding bit has been previously set in the control and status register), no interrupt signal is generated.
   d. The GO bit HDQ1W_CTRL_STS[4] is cleared at the end of a write operation.
4. The software must read the interrupt status register to clear the interrupt.
5. Repeat step 1 through step 4 for each successive byte to write.

23.4.2.2 Read Operation

The read operation sequence is as follows:

1. Write the command value to the TX write register (HDQ1W_TX_DATA).
2. Set DIR bit HDQ1W_CTRL_STS[1] to 0 and GO bit HDQ1W_CTRL_STS[4] to 1 and wait for the TX-complete interrupt.

NOTE: Steps 3 and 4 can be performed simultaneously.

3. Set DIR bit HDQ1W_CTRL_STS[1] to 1 to indicate a read.
4. Write 1 to GO bit HDQ1W_CTRL_STS[4] to initiate the read.
    a. The hardware detects a low-going edge on the line (generated by the slave) and receives 8 bits of data in the RX receive buffer register (HDQ1W_RX_DATA). The first bit received is the LSB and the last bit is the MSB. The master performs this step as soon as the slave sends the data, irrespective of the state of GO bit HDQ1W_CTRL_STS[4]. However, an RX-complete interrupt is generated only when the software writes the GO bit.
    b. If a time-out occurs, the TIMEOUT bit HDQ1W_CTRL_STS[0] is set.
    c. Completion of the operation is indicated by setting the RX-complete flag in the interrupt status register (RXCOMPLETE bit HDQ1W_INT_STS[1]. If interrupts are masked (that is, the corresponding bit was previously set in the control and status register), no interrupt signal is generated.
    d. At the end of the read operation, the GO bit HDQ1W_CTRL_STS[4] is cleared. It is also cleared if a time-out is detected
5. The software must read the interrupt status register (HDQ1W_INT_STS) to determine whether an RX was successfully completed or a time-out occurred.
6. The software reads the RX receive buffer register (HDQ1W_RX_DATA) to retrieve the read data from the slave.
7. Repeat step 1 through step 6 for each successive byte.

NOTE: In HDQ mode, the address/command is written only once to the slave. However, after the first byte is received, an RX-complete interrupt is set. Therefore, the software must initiate the read of the second byte by setting the GO bit in the control and status register. The first byte received is shadowed and provided to the software while the hardware is fetching the second byte of data.

23.4.3 1-Wire Mode (SDQ) Basic Programming Model

23.4.3.1 Write Operation

The write operation sequence is as follows:

1. Write the ID, command, or data value to the TX write register (HDQ1W_TX_DATA).

NOTE: Steps 2 and 3 can be performed simultaneously.

2. Set DIR bit HDQ1W_CTRL_STS[1] to 0 to indicate a write operation.
3. Set GO bit HDQ1W_CTRL_STS[4] to 1 to start the transmission.
    a. The hardware sends the byte stored in the TX write register.
    b. In a write operation, the TIMEOUT bit is always cleared.
    c. When the operation is completed, the TX-complete flag is set in the interrupt status register (TXCOMPLETE bit HDQ_INT_STS [2]). No interrupt signal is generated if interrupts are masked (that is, the corresponding bit was previously set in the control and status register).
    d. The GO bit of the control and status register is cleared at the end of a write operation.
4. The software must read the interrupt status register (HDQ1W_INT_STS) to clear the interrupt.
5. Repeat step 1 through step 4 for each successive byte to write.

23.4.3.2 Read Operation

The read operation sequence is as follows:

1. Write the address to the TX write register (HDQ1W_TX_DATA).
2. Set DIR bit HDQ1W_CTRL_STS[1] to 0 and the GO bit HDQ1W_CTRL_STS[4] to 1 and wait for the TX-complete interrupt flag.
3. Write the command value to the TX write register (HDQ1W_TX_DATA).
4. Set DIR bit HDQ1W_CTRL_STS[1] to 0 and GO bit HDQ1W_CTRL_STS[4] to 1 and wait for the TX-complete interrupt flag.

NOTE: Steps 5 and 6 can be performed simultaneously.

5. Set DIR bit HDQ1W_CTRL_STS[1] to 1 to indicate a read.
6. Set GO bit HDQ1W_CTRL_STS[4] to 1 to start the transmission.
   a. The hardware (master) generates a low-going edge and clocks 8 bits of data into the RX receive register (HDQ1W_RX_DATA). The first bit received is the LSB and the last bit is the MSB.
   b. TIMEOUT bit HDQ1W_INT_STS[0] is always cleared in a read operation.
   c. When the operation is complete, the RX-complete flag is set in the interrupt status register (RXCOMPLETE bit HDQ1W_INT_STS[1]). No interrupt signal is generated if the interrupts are masked (that is, the corresponding bit was previously set in the control and status register).
   d. GO bit HDQ1W_CTRL_STS[4] is cleared at the end of the read. It is also cleared if a time-out occurs.
7. The software must read the interrupt status register to determine whether an RX was successfully completed or a time-out occurred.
8. The software reads the RX receive buffer register (HDQ1W_RX_DATA) to retrieve the read data from the slave.
9. Repeat step 1 through step 8 for each successive byte.

23.4.3.3 1-Wire Bit Mode Operation

Select the single-bit mode by setting the 1_WIRE_SINGLE_BIT bit HDQ1W_CTRL_STS[7] to 1. In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, the corresponding interrupt flag is set (that is, there is an RX-complete (RXCOMPLETE bit HDQ1W_INT_STS[1]) for a read operation and a TX-complete (TXCOMPLETE bit HDQ1W_INT_STS[2]) for a write operation). Bit 0 of the RX register (HDQ1W_RX_DATA) is updated each time a bit is received; bit 0 of the TX register (HDQ1W_TX_DATA) contains the bit of data to be sent.

23.4.4 Power Management

The software has independent control of the two clock domains (interconnect clock: HDQ_ICLK and functional clock: HDQ_FCLK). Because there is no acknowledge mechanism from the HDQ/1-Wire module to an idle request, the software must ensure that a clock is not shut off while a transfer is being processed (the data would be lost).

If the autoidle function (AUTOIDLE bit HDQ1W_SYSCONFIG[0] set to 1) provides a safe transfer (the module wakes up the HDQ_ICLK as soon as a transfer is initiated), the power-down mode and the PRCM idle requests (through the whole L4 clock domain idle request) must be handled carefully.

The following sections describe the steps to follow to use the power-down and idle modes.

23.4.4.1 Module Power-Down Mode

1. Before shutting off the HDQ_FCLK, wait for an RX-complete or a TX-complete interrupt.
   - In a read operation, the transfer is completed when the RX-complete flag (RXCOMPLETE bit HDQ1W_INT_STS [1]) generates an interrupt.
   - In a write operation, the transfer is completed when the TX-complete flag (TXCOMPLETE bit HDQ1W_INT_STS [2]) generates an interrupt. The software must check whether the interrupt was generated after the address/command byte was sent or after the data byte was sent. The clock must not be shut off after the command/ address byte is sent; otherwise, the data is not written to the slave.

   HDQ1W_INT_STS must be read to clear the interrupt condition.
2. Set the CLOCKENABLE bit HDQ1W_CTRL_STS[5] to 0 to disable the clock.

   Do not access the module registers after the software has put the module into power-down mode except to write to the clock-enable bit to take the module out of power-down mode.

23.4.4.2 System Idle Mode

This section describes the steps to follow at the module level before enabling the idle mode at the system level (for more information about the system power management scheme, see Chapter 6, *Power, Reset, and Clock Management*.

As part of the L4 interconnect clock domain, the HDQ/1-Wire clocks can be cut at the PRCM level. HDQ_FCLK can be cut if the EN_HDQ bit PRCM.CM_FCLKEN1_CORE [22] is set to 0 and no other modules require CORE_12M_FCLK. The software must verify that no transfer is in progress.

In a read operation:

1. Wait for an RX-complete interrupt.

   In a read operation, the transfer is completed when the RX-complete flag (RXCOMPLETE bit HDQ1W_INT_STS [1]) generates an interrupt.
2. Read the HDQ1W_INT_STS to clear the read-complete interrupt flag.
3. Read the HDQ1W_RX_DATA to retrieve the read data.
4. The HDQ_ICLK can be shut off by entering the system idle mode.

In a write operation:

1. Wait for a TX-complete interrupt.

   In a write operation, the transfer is completed when the TX-complete flag (TXCOMPLETE bit HDQ1W_INT_STS[2]) generates an interrupt. The software must check whether the interrupt was generated after the address/command byte was sent or after the data byte was sent. The clock must not be shut off after the command/address byte is sent; otherwise, the data is not written to the slave.
2. Read the HDQ1W_INT_STS to clear the TX-complete interrupt flag.
3. The HDQ_ICLK can be shut off by entering the system idle mode.

Concerning HDQ_ICLK, two situations can occur:

- The clock is no longer required and EN_HDQ bit PRCM.CM_ ICLKEN1_CORE[22] is set by software. In this case, the clock is cut off, provided no other modules require it. Before setting the EN_HDQ bit, the software must follow the steps described in this section.
- AUTO_HDQ bit PRCM.CM_AUTOIDLE1_CORE[22] is set. In this case, the software must verify that all HDQ/1-Wire transfers are complete before enabling the L4 interconnect clock domain idle mode. Otherwise, the HDQ/1-Wire has no way to prevent the clock from being cut, because no hardware mechanism exists. The steps listed in this section must be verified before putting the L4 clock domain into idle state.

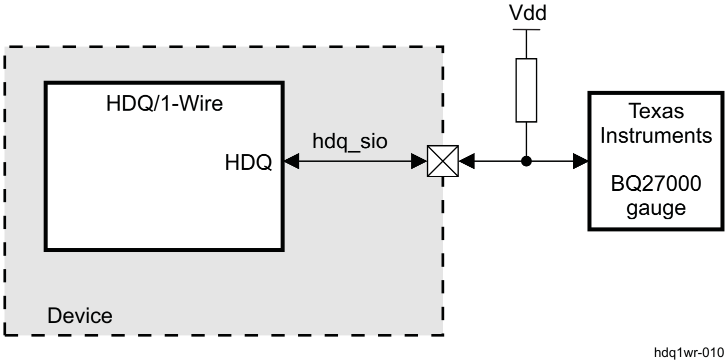
23.5 Use Cases

23.5.1 *How to Configure the HDQ/1-Wire when Connected with a BQ27000 Gauge*

23.5.1.1 Environment

Figure 23-9 details the device connections with the BQ27000 gauge.

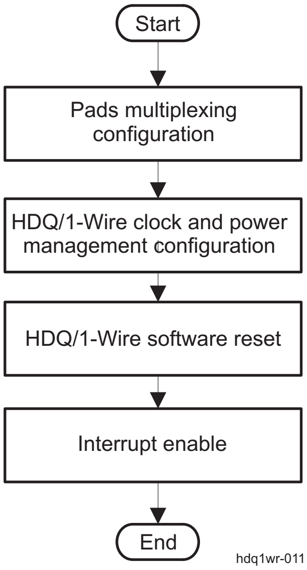
Figure 23-9. Environment



23.5.1.2 Programming Flow

This section details the programming flow of the HDQ/1-Wire. Figure 23-10 shows the main steps of this configuration. The BQ27000 gauge uses the HDQ mode.

Figure 23-10. HDQ/1-Wire Configuration in HDQ Mode



23.5.1.3 Pad Configuration and HDQ/1-Wire Clock and Power Management

Table 23-6 shows the pad multiplexing and the clock and power management configuration to select for the HDQ/1-Wire module.

Table 23-6. Registers Print for HDQ/1-Wire Configuration

Register Name	Address	Value	Value description
CTRL_CONF_UART3_RTSN	0x44E1 0A34	0xxxxx 0001	Configure hdq_sio pad in mode 1
PRCM_CM_PER_HDQ1W_CLKCTRL	0x4DF 8CA0	0x0000 0002	Enable HDQ/1-Wire Functional clock
HDQ_CTRL_STS	0x4834 700C	0x0000 0020	Enable clocks and select the HDQ mode

23.5.1.4 HDQ/1-Wire Software Reset

Perform a software reset as described in Figure 23-11.

Figure 23-11. Software Reset Flowchart

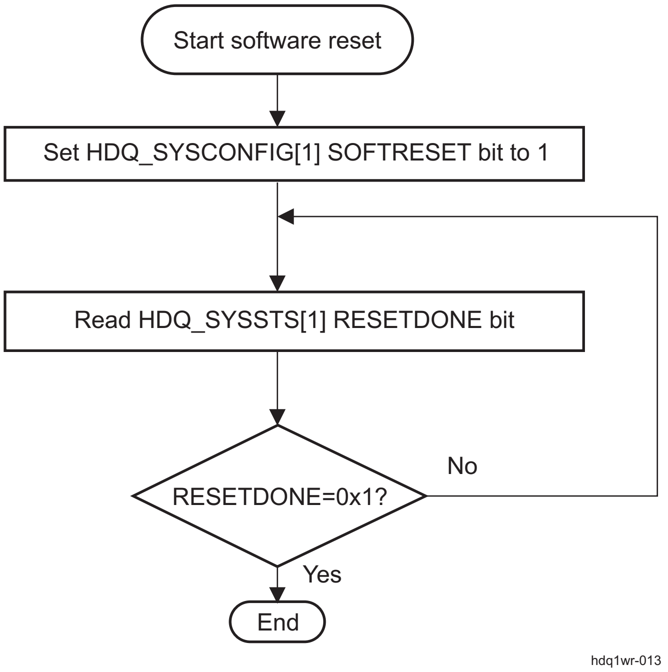

Table 23-7 describes the registers to be configured for the HDQ/1-Wire software reset step.

Table 23-7. Registers Print for HDQ/1-Wire Software Reset

Register Name	Address	Value	Value description
HDQ_SYSCONFIG	0x4834 7014	0x0000 0002	Initiate a software reset. The HDQ_SYSCONFIG[1] SOFTRESET is automatically reset by hardware.
HDQ_SYSSTS	0x4834 7018	0x0000 0001	The HDQ_SYSSTATUS[0] RESETDONE is set to 1 when the reset sequence is done.

23.5.1.5 Interrupts Enable

Table 23-8 describes the registers to be configured for the interrupts enable step and the use case values.

Table 23-8. Registers Print for HDQ/1-Wire Interrupts Enable

Register Name	Address	Value	Value description
HDQ_CTRL_STS	0x4834 700C	0x0000 0060	Enable Interrupts

23.5.1.6 Read and Write Operations

The Read and Write operations in HDQ mode are described in Section 23.4.2.

Some write operations are needed to configure the BQ27000 gauge: for example, it is necessary to write a COMMAND KEY (0xA9 or 0x56) in the Device Control Register of the gauge. For more information, see the TI BQ27000 datasheet (SLUS556).

23.6 HDQ/1-Wire Registers

23.6.1 HDQ1W Registers

Table 23-9 lists the memory-mapped registers for the HDQ1W. All register offset addresses not listed in Table 23-9 should be considered as reserved locations and the register contents should not be modified.

Table 23-9. HDQ1W REGISTERS

Offset	Acronym	Register Name	Section
0h	HDQ1W_REVISION		Section 23.6.1.1

Multichannel Audio Serial Port (McASP)

This chapter describes the McASP of the device.

Topic **Page**

24.1 Introduction

24.1.1 Purpose of the Peripheral

The multichannel audio serial port (McASP) functions as a general-purpose audio serial port optimized for the needs of multichannel audio applications. The McASP is useful for time-division multiplexed (TDM) stream, Inter-Integrated Sound (I2S) protocols, and intercomponent digital audio interface transmission (DIT). The McASP consists of transmit and receive sections that may operate synchronized, or completely independently with separate master clocks, bit clocks, and frame syncs, and using different transmit modes with different bit-stream formats. The McASP module also includes serializers that can be individually enabled to either transmit or receive.

24.1.2 Features

Features of the McASP include:

- Two independent clock generator modules for transmit and receive.
  - Clocking flexibility allows the McASP to receive and transmit at different rates. For example, the McASP can receive data at 48 kHz but output up-sampled data at 96 kHz or 192 kHz.
- Independent transmit and receive modules, each includes:
  - Programmable clock and frame sync generator.
  - TDM streams from 2 to 32, and 384 time slots.
  - Support for time slot sizes of 8, 12, 16, 20, 24, 28, and 32 bits.
  - Data formatter for bit manipulation.
- Individually assignable serial data pins (up to 6 pins).
- Glueless connection to audio analog-to-digital converters (ADC), digital-to-analog converters (DAC), codec, digital audio interface receiver (DIR), and S/PDIF transmit physical layer components.
- Wide variety of I2S and similar bit-stream format.
- Integrated digital audio interface transmitter (DIT) supports (up to 10 transmit pins):
  - S/PDIF, IEC60958-1, AES-3 formats.
  - Enhanced channel status/user data RAM.
- 384-slot TDM with external digital audio interface receiver (DIR) device.
  - For DIR reception, an external DIR receiver integrated circuit should be used with I2S output format and connected to the McASP receive section.
- Extensive error checking and recovery.
  - Transmit underruns and receiver overruns due to the system not meeting real-time requirements.
  - Early or late frame sync in TDM mode.
  - Out-of-range high-frequency master clock for both transmit and receive.
  - External error signal coming into the AMUTEIN input.
  - DMA error due to incorrect programming.

24.1.3 Protocols Supported

The McASP supports a wide variety of protocols.

- Transmit section supports:
  - Wide variety of I2S and similar bit-stream formats.
  - TDM streams from 2 to 32 time slots.
  - S/PDIF, IEC60958-1, AES-3 formats.
- Receive section supports:
  - Wide variety of I2S and similar bit-stream formats.
  - TDM streams from 2 to 32 time slots.
  - TDM stream of 384 time slots specifically designed for easy interface to external digital interface receiver (DIR) device transmitting DIR frames to McASP using the I2S protocol (one time slot for each DIR subframe).

The transmit and receive sections may each be individually programmed to support the following options on the basic serial protocol:

- Programmable clock and frame sync polarity (rising or falling edge): ACLKR/X, AHCLKR/X, and AFSR/X.
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported.
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length.
- First-bit data delay: 0, 1, 2 bit clocks.
- Left/right alignment of word inside slot.
- Bit order: MSB first or LSB first.
- Bit mask/pad/rotate function.
  - Automatically aligns data internally in either Q31 or integer formats.
  - Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit).

In DIT mode for McASP, additional features of the transmitter are:

- Transmit-only mode 384 time slots (subframe) per frame.
- Bi-phase encoded 3.3 V output.
- Support for consumer and professional applications.
- Channel status RAM (384 bits).
- User data RAM (384 bits).
- Separate valid bit (V) for subframe A, B.

In I2S mode, the transmit and receive sections can support simultaneous transfers on up to all serial data pins operating as 192 kHz stereo channels.

In DIT mode, the transmitter can support a 192 kHz frame rate (stereo) on up to all serial data pins simultaneously (note that the internal bit clock for DIT runs two times faster than the equivalent bit clock for I2S mode, due to the need to generate Biphase Mark Encoded Data).

24.1.4 Unsupported McASP Features

The unsupported McASP features in this device include the following.

Table 24-1. Unsupported McASP Features

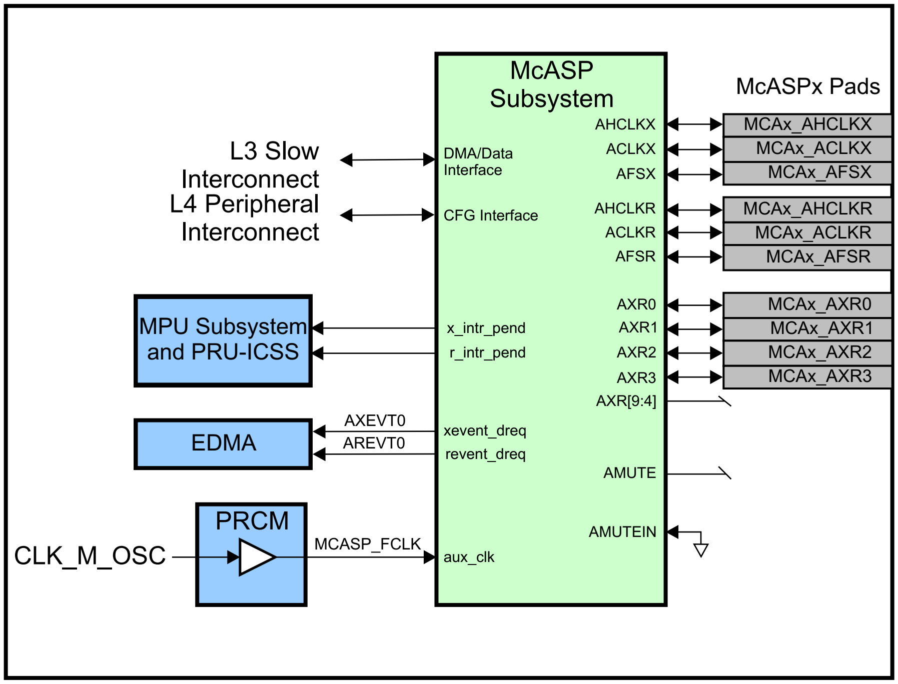
Feature	Reason
AXR[9:4]	Signals are not pinned out
AMUTE	Not connected
AMUTEIN	Not connected

24.2 Integration

The device contains two instantiations of the McASP subsystem: McASP0 and McASP1. The McASP subsystem includes a McASP peripheral, and transmit/receive buffers.

Each McASP is configured with four serializers.

Figure 24-1. McASP0–1 Integration



24.2.1 McASP Connectivity Attributes

The general connectivity attributes for the McASP modules are summarized in Table 24-2

Table 24-2. McASP Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3S_GCLK (OCP Clock) PD_PER_MCASP_FCLK (Aux Clock)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 Transmit Interrupt per instance x_intr_pend - to MPU Subsystem (MCATXINTx) and PRU-ICSS (mcasp_x_intr_pend) 1 Receive Interrupt r_intr_pend - to MPU Subsystem (MCARXINTx) and PRU-ICSS (mcasp_r_intr_pend)
DMA Requests	2 DMA requests per instance to EDMA (Transmit: AXEVTx, Receive: AREVTx)
Physical Address	L3 Slow slave port (data) L4 Peripheral slave port (CFG)

24.2.2 McASP Clock and Reset Management

The McASP module uses functional clocks either generated internally (master mode) or supplied from its serial interface (slave mode). The internal interconnect interface clock is used for the module internal OCP interface. Internal registers select the source of the functional clocks and the applied divider ratio.

Table 24-3. McASP Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
ocp_clk Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l3s_gclk From PRCM
auxclk Functional clock	26 MHz	CLK_M_OSC	pd_per_mcasp_fclk From PRCM

24.2.3 McASP Pin List

The McASP external interface signals are shown in Table 24-4.

Table 24-4. McASP Pin List

Pin	Type	Description
McASP*x*_AXR[3:0]	I/O	Audio transmit/receive pin
McASP*x*_ACLKX(1)	I/O	Transmit clock
McASP*x*_FSX(1)	I/O	Frame synch for transmit
McASP*x*_AHCLKX(1)	I/O	High speed transmit clock
McASP*x*_ACLKR(1)	I/O	Receive clock
McASP*x*_FSR(1)	I/O	Frame synch for receive
McASP*x*_AHCLKR(1)	I/O	High speed receive clock

(1) These signals are also used as inputs to re-time or sync data. The associated CONF_<module>_pin_RXACTIVE bit for these signals must be set to 1 to enable the inputs back to the module. It is also recommended to place a 33-ohm resistor in series (close to the processor) on each of these signals to avoid signal reflections.

24.3 Functional Description

24.3.1 Overview

Figure 24-2 shows the major blocks of the McASP. The McASP has independent receive/transmit clock generators and frame sync generators, error-checking logic, and up to four serial data pins. See the device-specific data manual for the number of data pins available on your device.

All the McASP pins on the device may be individually programmed as general-purpose I/O (GPIO) if they are not used for serial port functions.

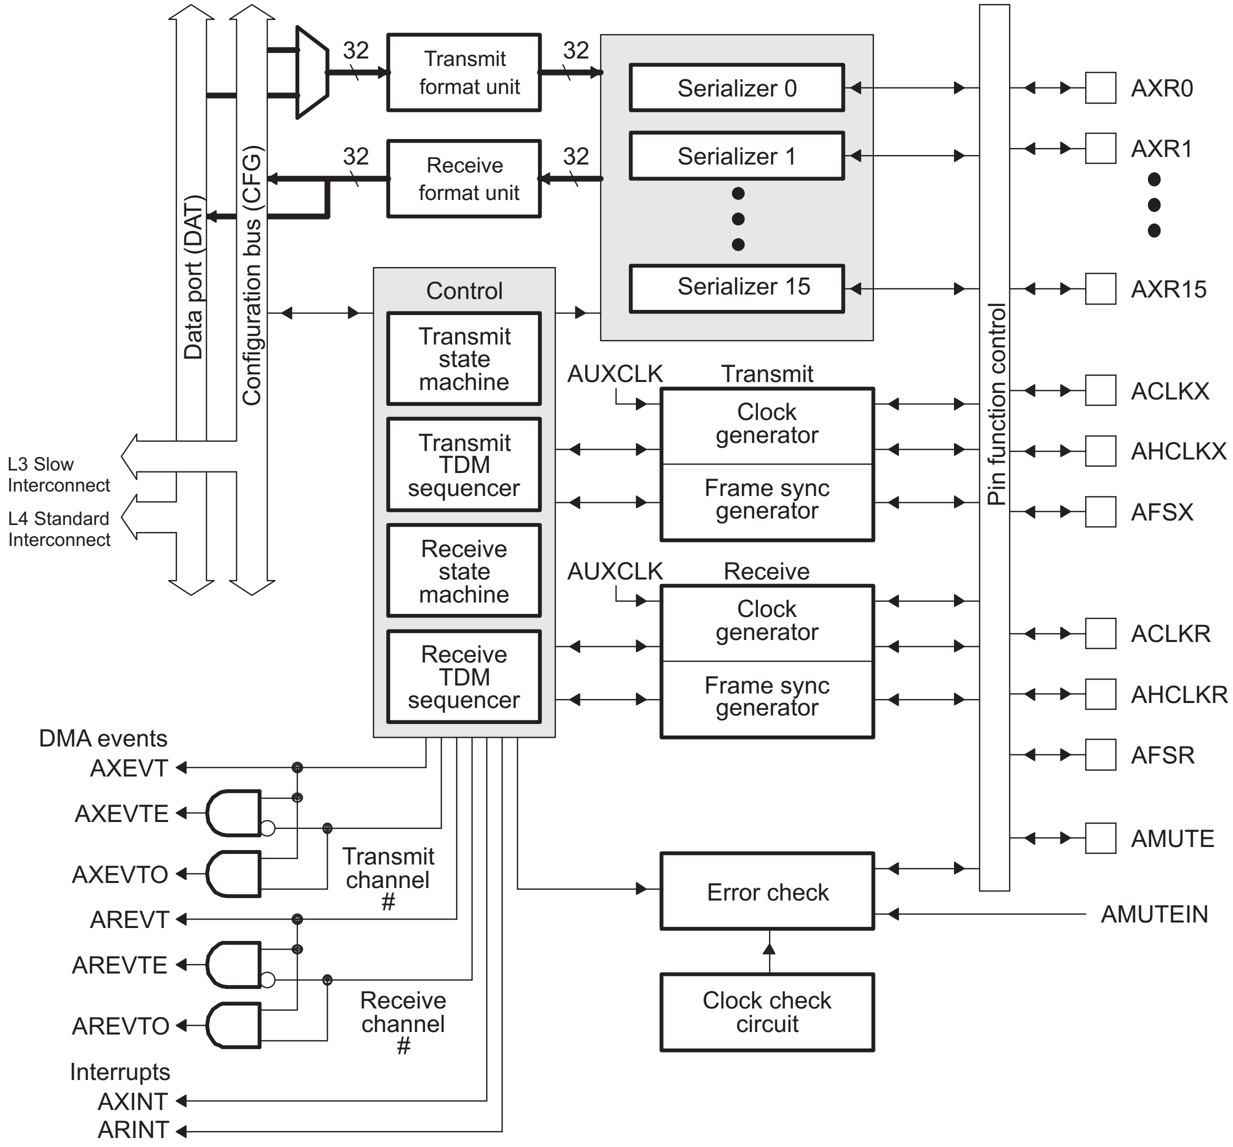
The McASP includes the following pins:

- Serializers;
  - Data pins AXRn: Up to four pins.
- Transmit clock generator:
  - AHCLKX: McASP transmit high-frequency master clock.
  - ACLKX: McASP transmit bit clock.
- Transmit Frame Sync Generator;
  - AFSX: McASP transmit frame sync or left/right clock (LRCLK).
- Receive clock generator;
  - AHCLKR: McASP receive high-frequency master clock.
  - ACLKR: McASP receive bit clock.
- Receive Frame Sync Generator;
  - AFSR: McASP receive frame sync or left/right clock (LRCLK).
- Mute in/out;
  - AMUTEIN: McASP mute input (from external device).
  - AMUTE: McASP mute output.
  - Data pins AXRn.

24.3.2 Functional Block Diagram

Figure 24-2 shows the major blocks of the McASP. The McASP has independent receive/transmit clock generators and frame sync generators.

Figure 24-2. McASP Block Diagram



A McASP has 6 serial data pins.

B AMUTEIN is not a dedicated McASP pin, but typically comes from one of the external interrupt pins.

24.3.2.1 System Level Connections

Figure 24-3 through Figure 24-7 show examples of McASP usage in digital audio encoder/decoder systems.

Figure 24-3. McASP to Parallel 2-Channel DACs

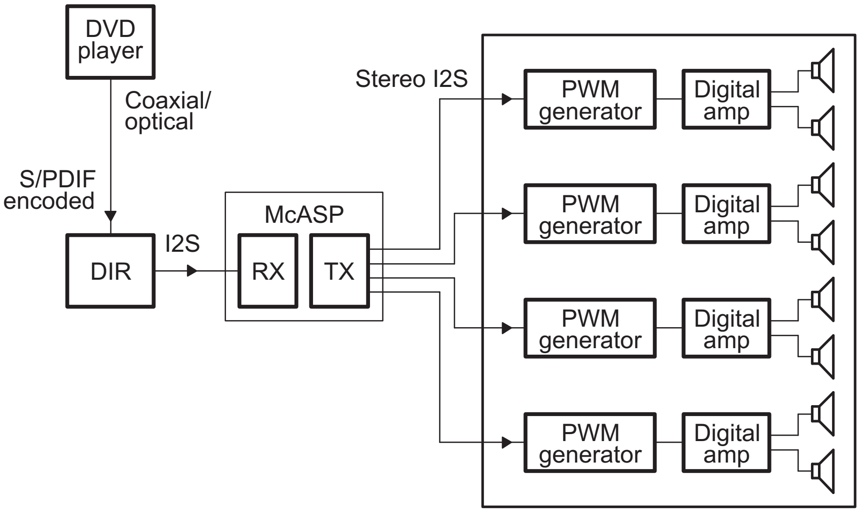

Figure 24-6. McASP as Digital Audio Encoder

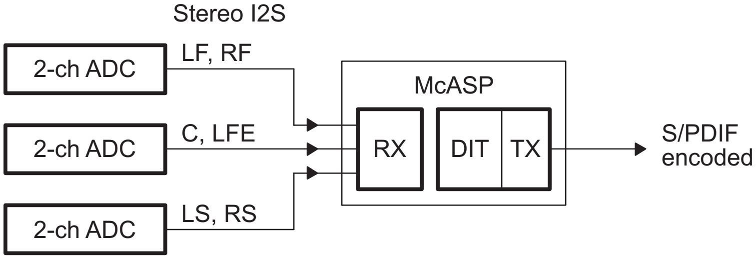

Figure 24-7. McASP as 16 Channel Digital Processor

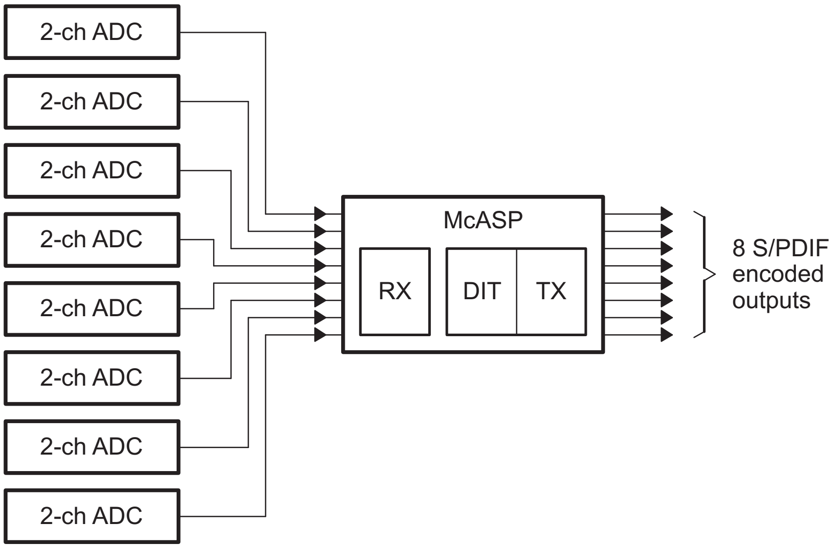


24.3.3 Industry Standard Compliance Statement

The McASP supports the following industry standard interfaces.

24.3.3.1 TDM Format

The McASP transmitter and receiver support the multichannel, synchronous time-division-multiplexed (TDM) format via the TDM transfer mode. Within this transfer mode, a wide variety of serial data formats are supported, including formats compatible with devices using the Inter-Integrated Sound (I2S) protocol. This section briefly discusses the TDM format and the I2S protocol.

24.3.3.1.1 TDM Format

The TDM format is typically used when communicating between integrated circuit devices on the same printed circuit board or on another printed circuit board within the same piece of equipment. For example, the TDM format is used to transfer data between the processor and one or more analog-to-digital converter (ADC), digital-to-analog converter (DAC), or S/PDIF receiver (DIR) devices.

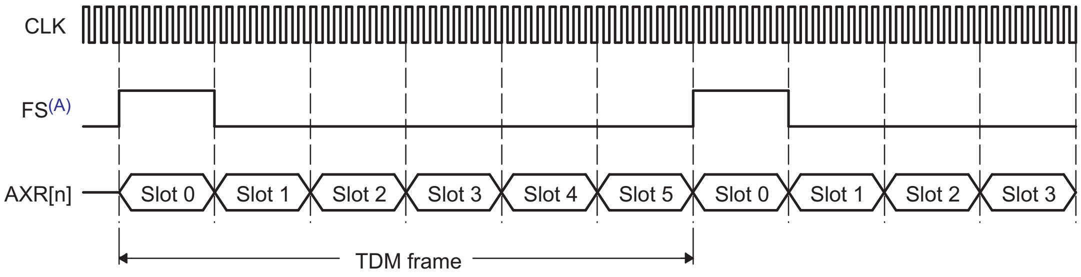
The TDM format consists of three components in a basic synchronous serial transfer: the clock, the data, and the frame sync. In a TDM transfer, all data bits (AXRn) are synchronous to the serial clock (ACLKX or ACLKR). The data bits are grouped into words and slots (as defined in Section 24.3.4). The "slots" are also commonly referred to as "time slots" or "channels" in TDM terminology. A frame consists of multiple slots (or channels). Each TDM frame is defined by the frame sync signal (AFSX or AFSR). Data transfer is continuous and periodic, since the TDM format is most commonly used to communicate with data converters that operate at a fixed sample rate.

There are no delays between slots. The last bit of slot N is followed immediately on the next serial clock cycle with the first bit of slot N + 1, and the last bit of the last slot is followed immediately on the next serial clock with the first bit of the first slot. However, the frame sync may be offset from the first bit of the first slot with a 0, 1, or 2-cycle delay.

It is required that the transmitter and receiver in the system agree on the number of bits per slot, since the determination of a slot boundary is not made by the frame sync signal (although the frame sync marks the beginning of slot 0 and the beginning of a new frame).

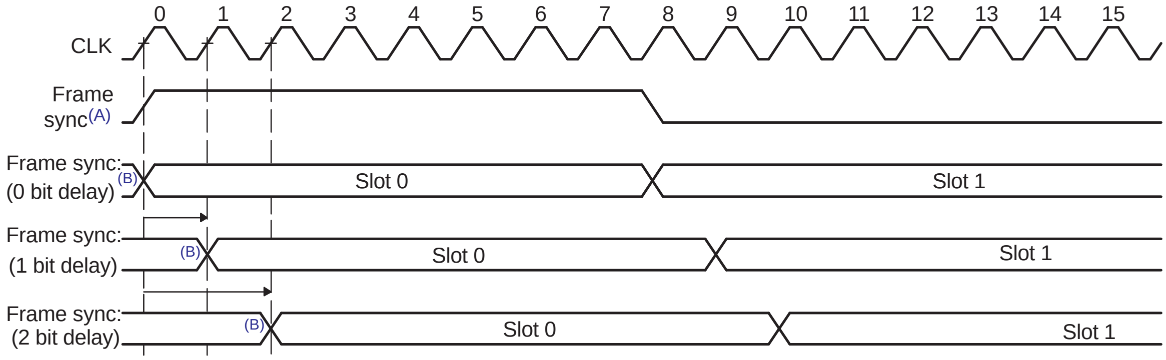
Figure 24-8 shows the TDM format. Figure 24-9 shows the different bit delays from the frame sync.

Figure 24-8. TDM Format–6 Channel TDM Example



A FS duration of slot is shown. FS duration of single bit is also supported.

Figure 24-9. TDM Format Bit Delays from Frame Sync



A FS duration of slot is shown. FS duration of single bit is also supported.

B Last bit of last slot of previous frame. No gap between this bit and the first bit of slot 0 is allowed.

In a typical audio system, one frame of data is transferred during each data converter sample period f_s. To support multiple channels, the choices are to either include more time slots per frame (thus operating with a higher bit clock rate), or to use additional data pins to transfer the same number of channels (thus operating with a slower bit clock rate).

For example, a particular six channel DAC may be designed to transfer over a single serial data pin AXRn as shown in Figure 24-8. In this case the serial clock must run fast enough to transfer a total of 6 channels within each frame period. Alternatively, a similar six channel DAC may be designed to use three serial data pins AXR[0,1,2], transferring two channels of data on each pin during each sample period. In the latter case, if the sample period remains the same, the serial clock can run three times slower than the former case. The McASP is flexible enough to support either type of DAC.

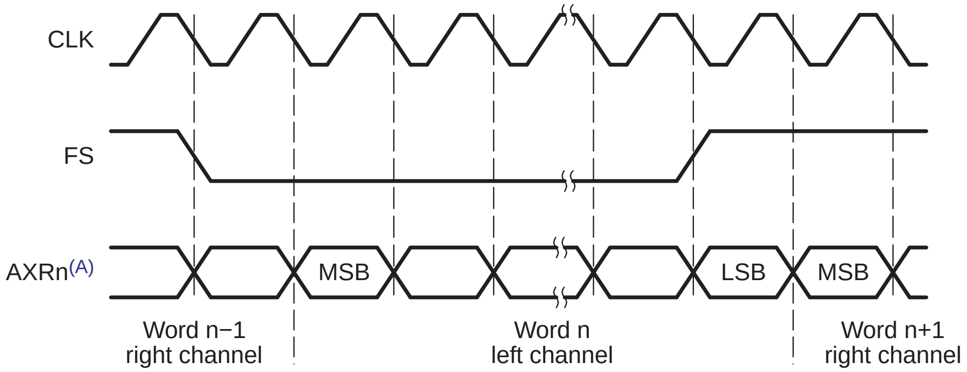
24.3.3.1.2 Inter-Integrated Sound (I2S) Format

The inter-integrated sound (I2S) format is used extensively in audio interfaces. The TDM transfer mode of the McASP supports the I2S format when configured to 2 slots per frame.

I2S format is specifically designed to transfer a stereo channel (left and right) over a single data pin AXRn. "Slots" are also commonly referred to as "channels". The frame width duration in the I2S format is the same as the slot size. The frame signal is also referred to as "word select" in the I2S format. Figure 24-10 shows the I2S protocol.

The McASP supports transfer of multiple stereo channels over multiple AXRn pins.

Figure 24-10. Inter-Integrated Sound (I2S) Format



A 1 to 6 data pins may be supported.

24.3.3.2 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 3.3V biphase-mark encoded output. The S/PDIF format is supported by the digital audio interface transmit (DIT) transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

24.3.3.2.1 Biphase-Mark Code (BMC)

In S/PDIF format, the digital signal is coded using the biphase-mark code (BMC). The clock, frame, and data are embedded in only one signal—the data pin AXRn. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals to the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. Figure 24-11 and Table 24-5 show how data is encoded to the BMC format.

As shown in Figure 24-11, the frequency of the clock is twice the unencoded data bit rate. In addition, the clock is always programmed to 128 × f_s, where f_s is the sample rate (see Section 24.3.3.2.3 for details on how this clock rate is derived based on the S/PDIF format). The device receiving in S/PDIF format can recover the clock and frame information from the BMC signal.

Figure 24-11. Biphase-Mark Code (BMC)

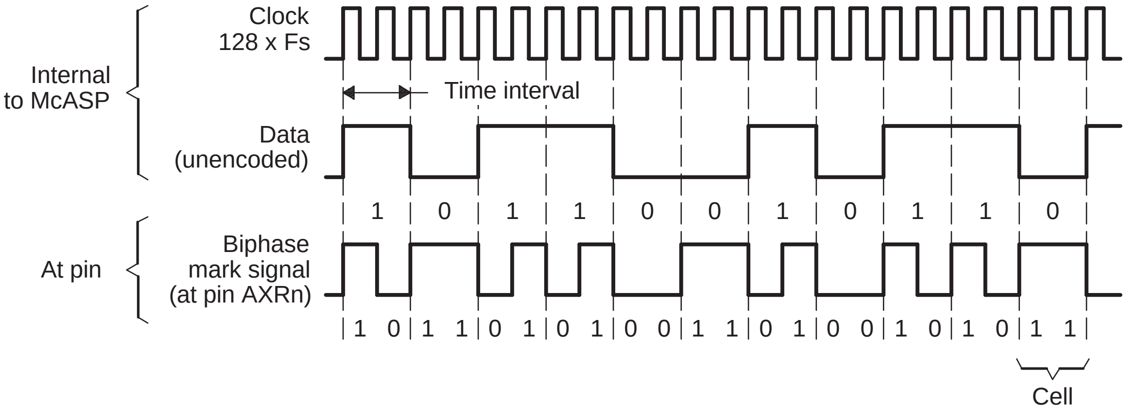


Table 24-5. Biphase-Mark Encoder

Data (Unencoded)	Previous State at Pin AXRn	BMC-Encoded Cell Output at AXRn
0	0	11
0	1	00
1	0	10
1	1	01

24.3.3.2.2 Subframe Format

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered from 0 to 31. Figure 24-12 shows a subframe.

- **Time intervals 0-3** carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is *not* encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See Table 24-6.
- **Time intervals 4-27** carry the audio sample word in linear 2s-complement representation. The most-significant bit (MSB) is carried by time interval 27. When a 24-bit coding range is used, the least-significant bit (LSB) is in time interval 4. When a 20-bit coding range is used, time intervals 8-27 carry the audio sample word with the LSB in time interval 8. Time intervals 4-7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (either 20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field may carry any other information.
- **Time interval 28** carries the validity bit (V) associated with the main data field in the subframe.
- **Time interval 29** carries the user data channel (U) associated with the main data field in the subframe.
- **Time interval 30** carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- **Time interval 31** carries a parity bit (P) such that time intervals 4-31 carry an even number of 1s and an even number of 0s (even parity). As shown in Table 24-6, the preambles (time intervals 0-3) are also defined with even parity.

Figure 24-12. S/PDIF Subframe Format

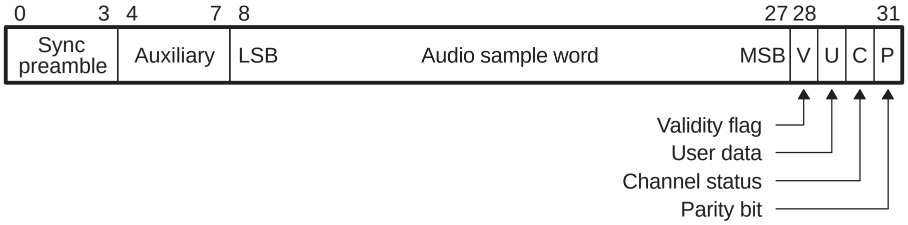

Table 24-6. Preamble Codes

Preamble Code[1]	Previous Logical State	Logical States on pin AXRn[2]	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

[1] Historically, preamble codes are referred to as B, M, W. For use in professional applications, preambles are referred to as Z, X, Y, respectively.

[2] The preamble is not BMC encoded. Each logical state is synchronized to the serial clock. These 8 logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

As shown in Table 24-6, the McASP DIT only generates one polarity of preambles and it assumes the previous logical state to be 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the AXRn pin before continuing with the next transmission.

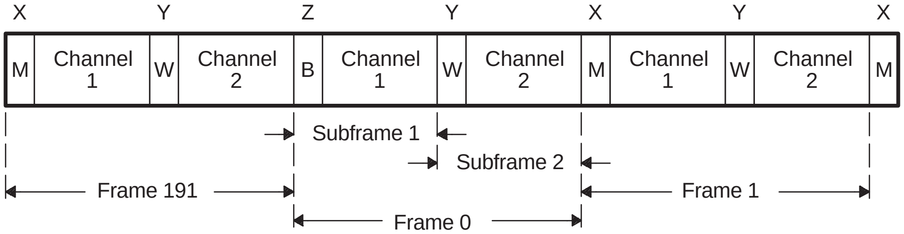
24.3.3.2.3 Frame Format

An S/PDIF frame is composed of two subframes (Figure 24-13). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency f_s. The S/PDIF format clock rate is therefore 128 × f_s (128 = 32 cells/subframe × 2 clocks/cell × 2 subframes/sample). For example, for an S/PDIF stream at a 192 kHz sampling frequency, the serial clock is 128 × 192 kHz = 24.58 MHz.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data. The first subframe (**left** or **A** channel in stereophonic operation and **primary** channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (**right** or **B** channel in stereophonic operation and **secondary** channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

Figure 24-13. S/PDIF Frame Format



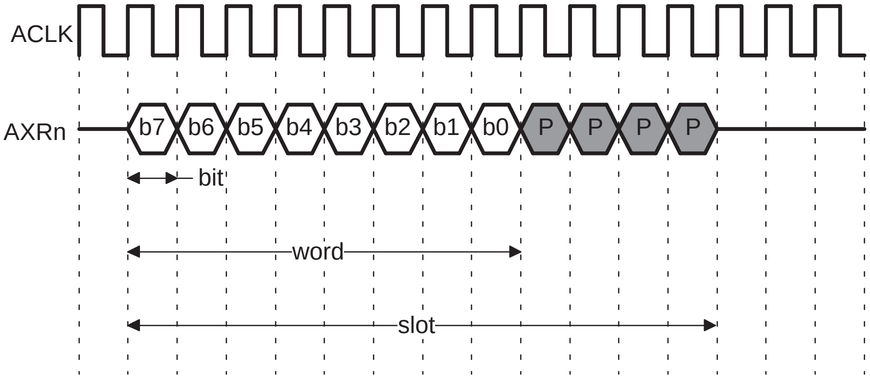
24.3.4 Definition of Terms

The serial bit stream transmitted or received by the McASP is a long sequence of 1s and 0s, either output or input on one of the audio transmit/receive pins (AXRn). However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. Figure 24-14 shows two of the three basic components—the clock (ACLK) and the data (AXRn). Figure 24-14 does not specify whether the clock is for transmit (ACLKX) or receive (ACLKR) because the definitions of terms apply to both receive and transmit interfaces. In operation, the transmitter uses ACLKX as the serial clock, and the receiver uses ACLKR as the serial clock. Optionally, the receiver can use ACLKX as the serial clock when the transmitter and receiver of the McASP are configured to operate synchronously.

Bit	A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A 1 is represented by a logic high on the AXRn pin for the entire duration of the bit. A 0 is represented by a logic low on the AXRn pin for the entire duration of the bit.
Word	A word is a group of bits that make up the data being transferred between the processor and the external device. Figure 24-14 shows an 8-bit word.
Slot	A slot consists of the bits that make up the word, and may consist of additional bits used to pad the word to a convenient number of bits for the interface between the processor and the external device. In Figure 24-14, the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with 4 zeros (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits may be shifted in/out of the McASP on the AXRn pin either MSB or LSB first. When the word size is smaller than the slot size, the word may be aligned to the left (beginning) of the slot or to the right (end) of the slot. The additional bits in the slot not belonging to the word may be padded with 0, 1, or with one of the bits (the MSB or the LSB typically) from the data word. These options are shown in Figure 24-15.

Figure 24-14. Definition of Bit, Word, and Slot

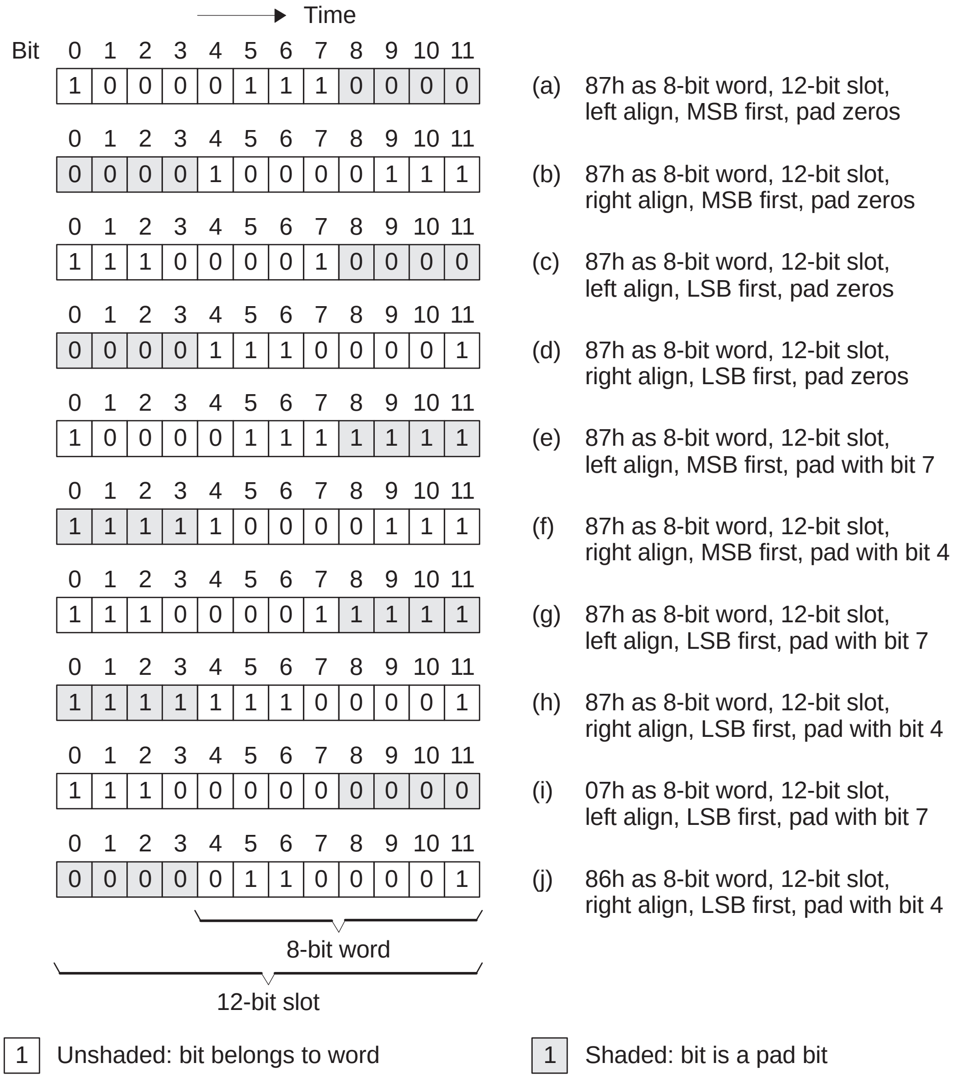


(1) b7:b0 - bits. Bits b7 to b0 form a word.

(2) P - pad bits. Bits b7 to b0, together with the four pad bits, form a slot.

(3) In this example, the data is transmitted MSB first, left aligned.

Figure 24-15. Bit Order and Word Alignment Within a Slot Examples



Bit	0	1	2	3	4	5	6	7	8	9	10	11	
	1	0	0	0	0	1	1	1	0	0	0	0	(a) 87h as 8-bit word, 12-bit slot, left align, MSB first, pad zeros
	0	0	0	0	1	0	0	0	0	1	1	1	(b) 87h as 8-bit word, 12-bit slot, right align, MSB first, pad zeros
	1	1	1	0	0	0	0	1	0	0	0	0	(c) 87h as 8-bit word, 12-bit slot, left align, LSB first, pad zeros
	0	0	0	0	1	1	1	0	0	0	0	1	(d) 87h as 8-bit word, 12-bit slot, right align, LSB first, pad zeros
	1	0	0	0	0	1	1	1	1	1	1	1	(e) 87h as 8-bit word, 12-bit slot, left align, MSB first, pad with bit 7
	1	1	1	1	1	0	0	0	0	1	1	1	(f) 87h as 8-bit word, 12-bit slot, right align, MSB first, pad with bit 4
	1	1	1	0	0	0	0	1	1	1	1	1	(g) 87h as 8-bit word, 12-bit slot, left align, LSB first, pad with bit 7
	1	1	1	1	1	1	1	0	0	0	0	1	(h) 87h as 8-bit word, 12-bit slot, right align, LSB first, pad with bit 4
	1	1	1	0	0	0	0	0	0	0	0	0	(i) 07h as 8-bit word, 12-bit slot, left align, LSB first, pad with bit 7
	0	0	0	0	0	1	1	0	0	0	0	1	(j) 86h as 8-bit word, 12-bit slot, right align, LSB first, pad with bit 4

1 Unshaded: bit belongs to word

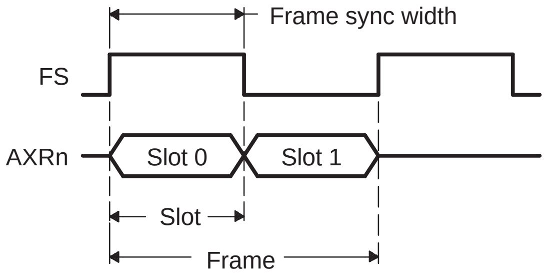
1 Shaded: bit is a pad bit

The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this document.

Frame	A frame contains one or multiple slots, as determined by the desired protocol. Figure 24-16 shows an example frame of data and the frame definitions. Figure 24-16 does not specify whether the frame sync (FS) is for transmit (AFSX) or receive (AFSR) because the definitions of terms apply to both receive and transmit interfaces. In operation, the transmitter uses AFSX and the receiver uses AFSR. Optionally, the receiver can use AFSX as the frame sync when the transmitter and receiver of the McASP are configured to operate synchronously.

This section only shows the generic definition of the frame sync. See Section 24.3.3 and Section 24.3.8.1 for details on the frame sync formats required for the different transfer modes and protocols (burst mode, TDM mode and I2S format, DIT mode and S/PDIF format).

Figure 24-16. Definition of Frame and Frame Sync Width



(1) In this example, there are two slots in a frame, and FS duration of slot length is shown.

Other terms used throughout the document:

TDM	Time-division multiplexed. See Section 24.3.3.1 for details on the TDM protocol.
DIR	Digital audio interface receive. The McASP does not natively support receiving in the S/PDIF format. The McASP supports I2S format output by an external DIR device.
DIT	Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on up to all data pins configured as outputs.
I2S	Inter-Integrated Sound protocol, commonly used on audio interfaces. The McASP supports the I2S protocol as part of the TDM mode (when configured as a 2-slot frame).
Slot or Time Slot	For TDM format, the term time slot is interchangeable with the term slot defined in this section. For DIT format, a McASP time slot corresponds to a DIT subframe.

24.3.5 Clock and Frame Sync Generators

The McASP clock generators are able to produce two independent clock zones: transmit and receive clock zones. The serial clock generators may be programmed independently for the transmit section and the receive section, and may be completely asynchronous to each other. The serial clock (clock at the bit rate) may be sourced:

- Internally - by passing through two clock dividers off the internal clock source (AUXCLK).
- Externally - directly from ACLKR/X pin.
- Mixed - an external high-frequency clock is input to the McASP on either the AHCLKX or AHCLKR pins, and divided down to produce the bit rate clock.

In the internal/mixed cases, the bit rate clock is generated internally and should be driven out on the ACLKX (for transmit) or ACLKR (for receive) pins. In the internal case, an internally-generated high-frequency clock may be driven out onto the AHCLKX or AHCLKR pins to serve as a reference clock for other components in the system.

The McASP requires a minimum of a bit clock and a frame sync to operate, and provides the capability to reference these clocks from an external high-frequency master clock. In DIT mode, it is possible to use only internally-generated clocks and frame syncs.

24.3.5.1 Transmit Clock

The transmit bit clock, ACLKX, (Figure 24-17) may be either externally sourced from the ACLKX pin or internally generated, as selected by the CLKXM bit. If internally generated (CLKXM = 1), the clock is divided down by a programmable bit clock divider (CLKXDIV) from the transmit high-frequency master clock (AHCLKX).

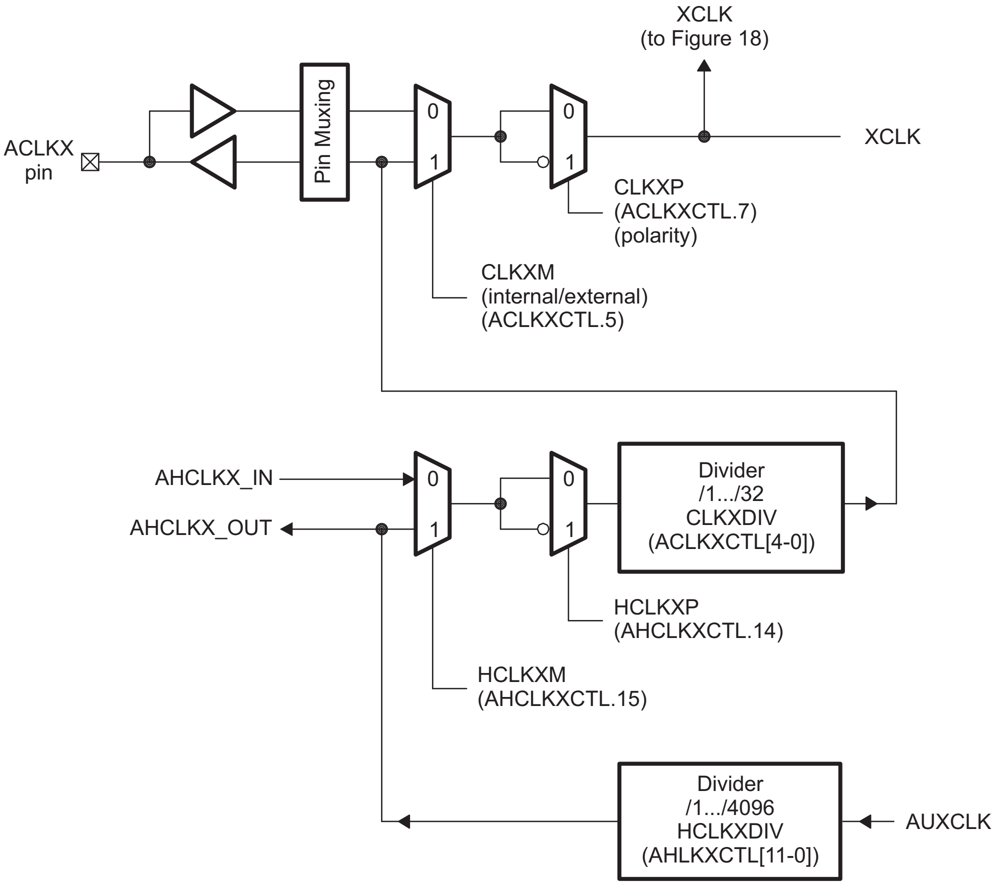
Internally, the McASP always shifts transmit data at the rising edge of the internal transmit clock, XCLK, (Figure 24-17). The CLKXP mux determines if ACLKX needs to be inverted to become XCLK. If CLKXP = 0, the CLKXP mux directly passes ACLKX to XCLK. As a result, the McASP shifts transmit data at the rising edge of ACLKX. If CLKXP = 1, the CLKX mux passes the inverted version of ACLKX to XCLK. As a result, the McASP shifts transmit data at the falling edge of ACLKX.

The transmit high-frequency master clock, AHCLKX, may be either externally sourced from the AHCLKX pin or internally generated, as selected by the HCLKXM bit. If internally generated (HCLKXM = 1), the clock is divided down by a programmable high clock divider (HCLKXDIV) from McASP internal clock source AUXCLK. The transmit high-frequency master clock may be (but is not required to be) output on the AHCLKX pin where it is available to other devices in the system.

The transmit clock configuration is controlled by the following registers:

- ACLKXCTL.
- AHCLKXCTL.

Figure 24-17. Transmit Clock Generator Block Diagram



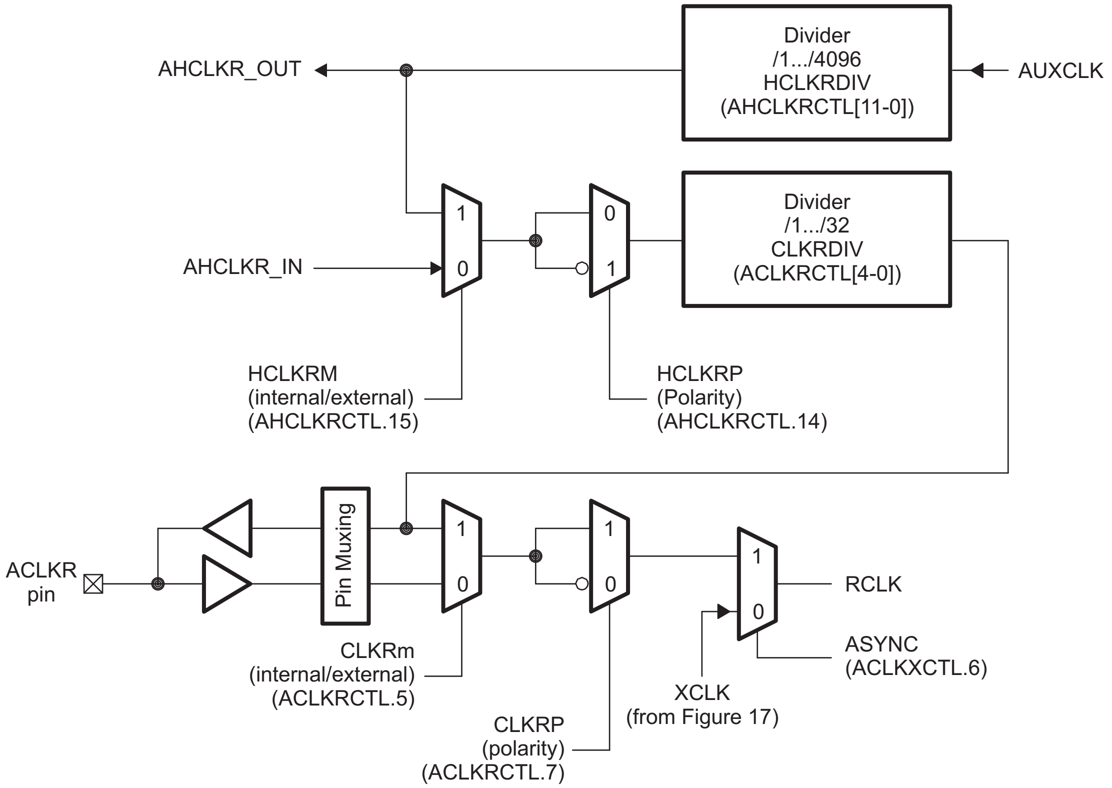
24.3.5.2 Receive Clock

The receiver also has the option to operate synchronously from the ACLKX and AFSX signals. This is achieved when the ASYNC bit in the transmit clock control register (ACLKXCTL) is cleared to 0 (see Figure 24-18). The receiver may be configured with different polarity (CLKRP) and frame sync data delay options from those options of the transmitter.

The receive clock configuration is controlled by the following registers:

- ACLKRCTL.
- AHCLKRCTL.

Figure 24-18. Receive Clock Generator Block Diagram



24.3.5.3 Frame Sync Generator

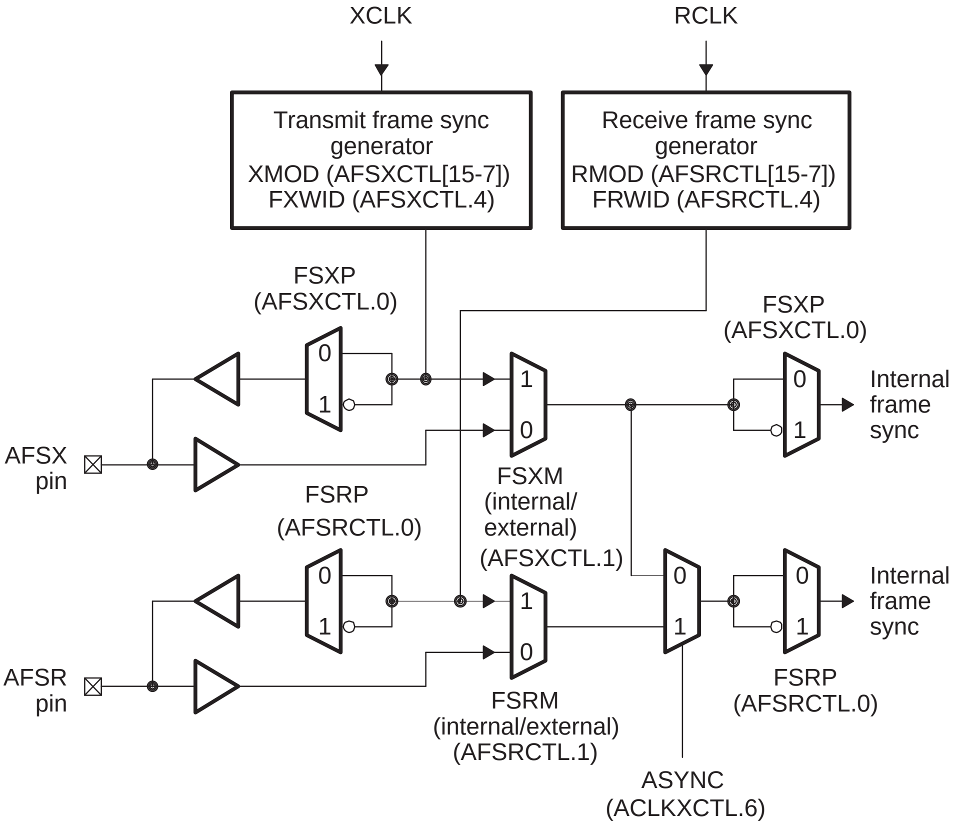
There are two different modes for frame sync: burst and TDM. A block diagram of the frame sync generator is shown in Figure 24-19. The frame sync options are programmed by the receive and transmit frame sync control registers (AFSRCTL and AFSXCTL). The options are:

- Internally-generated or externally-generated.
- Frame sync polarity: rising edge or falling edge.
- Frame sync width: single bit or single word.
- Bit delay: 0, 1, or 2 cycles before the first data bit.

The transmit frame sync pin is AFSX and the receive frame sync pin is AFSR. A typical usage for these pins is to carry the left/right clock (LRCLK) signal when transmitting and receiving stereo data.

Regardless if the AFSX/AFSR is internally generated or externally sourced, the polarity of AFSX/AFSR is determined by FSXP/FSRP, respectively, to be either rising or falling edge. If FSXP/FSRP = 0, the frame sync polarity is rising edge. If FSRP/FSRP = 1, the frame sync polarity is falling edge.

Figure 24-19. Frame Sync Generator Block Diagram



24.3.5.4 Clocking Examples

Some examples of processes using the McASP clocking and frame flexibility are:

- Receive data from a DVD at 48 kHz, but output up-sampled or decoded audio at 96 kHz or 192 kHz. This could be accomplished by inputting a high-frequency master clock (for example, 512 × receive FS), receiving with an internally-generated bit clock ratio of divide-by-8, and transmitting with an internally-generated bit clock ratio of divide-by-4 or divide-by-2.
- Transmit/receive data based on one sample rate (for example, 44.1 kHz), and transmit/receive data at a different sample rate (for example, 48 kHz).

24.3.5.5 Crystal Considerations

When choosing a high frequency input crystal for the device, consider the maximum functional clock frequency of the McASP module versus the maximum external receive/transmit clock AHCLKR/AHCLKX, especially when planning to generate the clocks internally. For example, if the maximum transmit clock AHCLKX is 25 MHz, a master oscillator CLK_M_OSC of 26 MHz requires a divide-by-2. However, master oscillator of 25 MHz enables full performance of the transmit clock.

24.3.6 Signal Descriptions

The signals used on the McASP audio interface are listed in Table 24-7.

Table 24-7. McASP Interface Signals

Pin	I/O/Z	Device Reset ($\overline{\text{RESET}}$ = 0)	Description
			Transmitter Control
AHCLKX	I/O/Z	Input	Transmit high-frequency master clock
AFSX	I/O/Z	Input	Transmit frame sync or left/right clock (LRCLK)
ACLKX	I/O/Z	Input	Transmit bit clock
			Receiver Control
AHCLKR	I/O/Z	Input	Receive high-frequency master clock
AFSR	I/O/Z	Input	Receive frame sync or left/right clock (LRCLK)
ACLKR	I/O/Z	Input	Receive bit clock
			Mute
AMUTE	I/O/Z	Input	Mute output
AMUTEIN	I/O/Z	Input	Mute input
			Data
AXRn	I/O/Z	Input	TX/RX data pins

24.3.7 Pin Multiplexing

The McASP signals share pins with other processor functions. For detailed information on the McASP pin multiplexing and configuration, see the pin multiplexing information in the device-specific data manual.

24.3.8 Transfer Modes

24.3.8.1 Burst Transfer Mode

The McASP supports a burst transfer mode, which is useful for nonaudio data such as passing control information between two processors. Burst transfer mode uses a synchronous serial format similar to the TDM mode. The frame sync generation is not periodic or time-driven as in TDM mode, but data driven, and the frame sync is generated for each data word transferred.

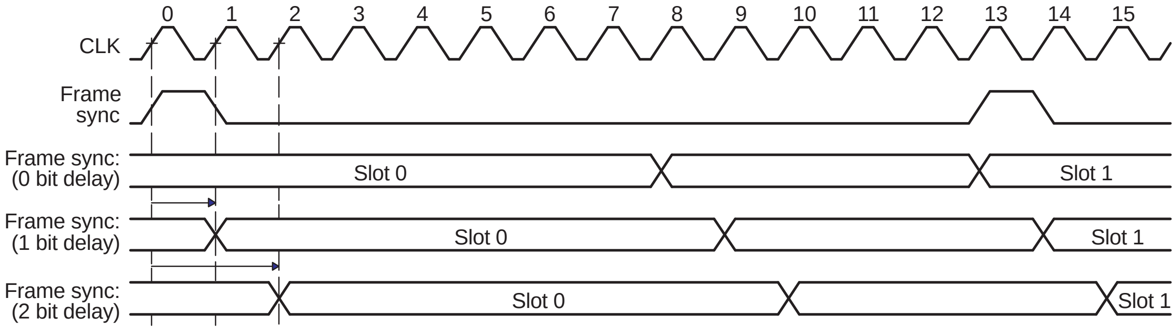
When operating in burst frame sync mode (Figure 24-20), as specified for transmit (XMOD = 0 in AFSXCTL) and receive (RMOD = 0 in AFSRCTL), one slot is shifted for each active edge of the frame sync signal that is recognized. Additional clocks after the slot and before the next frame sync edge are ignored.

In burst frame sync mode, the frame sync delay may be specified as 0, 1, or 2 serial clock cycles. This is the delay between the frame sync active edge and the start of the slot. The frame sync signal lasts for a single bit clock duration (FRWID = 0 in AFSRCTL, FXWID = 0 in AFSXCTL).

For transmit, when generating the transmit frame sync internally, the frame sync begins when the previous transmission has completed and when all the XBUF[n] (for every serializer set to operate as a transmitter) has been updated with new data.

For receive, when generating the receive frame sync internally, frame sync begins when the previous transmission has completed and when all the RBUF[n] (for every serializer set to operate as a receiver) has been read.

Figure 24-20. Burst Frame Sync Mode



The control registers must be configured as follows for the burst transfer mode. The burst mode specific bit fields are in bold face:

- PFUNC: The clock, frame, data pins must be configured for McASP function.
- PDIR: The clock, frame, data pins must be configured to the direction desired.
- PDOUT, PDIN, PDSET, PDCLR: Not applicable. Leave at default.
- GBLCTL: Follow the initialization sequence in Section 24.3.12.2 to configure this register.
- AMUTE: Not applicable. Leave at default.
- DLBCTL: If loopback mode is desired, configure this register according to Section 24.3.10.5, otherwise leave this register at default.
- DITCTL: DITEN must be left at default 0 to select non-DIT mode. Leave the register at default.
- RMASK/XMASK: Mask desired bits according to Section 24.3.9.2 and Section 24.3.10.3.
- RFMT/XFMT: Program all fields according to data format desired. See Section 24.3.10.3.
- AFSRCTL/AFSXCTL: Clear **RMOD/XMOD** bits to 0 to indicate burst mode. Clear **FRWID/FXWID** bits to 0 for single bit frame sync duration. Configure other fields as desired.
- ACLKRCTL/ACLKXCTL: Program all fields according to bit clock desired. See Section 24.3.5.
- AHCLKRCTL/AHCLKXCTL: Program all fields according to high-frequency clock desired. See Section 24.3.5.

- RTDM/XTDM: Program RTDMS0/XTDMS0 to 1 to indicate one active slot only. Leave other fields at default.
- RINTCTL/XINTCTL: Program all fields according to interrupts desired.
- RCLKCHK/XCLKCHK: Not applicable. Leave at default.
- SRCTLn: Program SRMOD to inactive/transmitter/receiver as desired. DISMOD is not applicable and should be left at default.
- DITCSRA[n], DITCSRB[n], DITUDRA[n], DITUDRB[n]: Not applicable. Leave at default.

24.3.8.2 Time-Division Multiplexed (TDM) Transfer Mode

The McASP time-division multiplexed (TDM) transfer mode supports the TDM format discussed in Section 24.3.3.1.

Transmitting data in the TDM transfer mode requires a minimum set of pins:

- ACLKX - transmit bit clock.
- AFSX - transmit frame sync (or commonly called left/right clock).
- One or more serial data pins, AXRn, whose serializers have been configured to transmit.

The transmitter has the option to receive the ACLKX bit clock as an input, or to generate the ACLKX bit clock by dividing down the AHCLKX high-frequency master clock. The transmitter can either generate AHCLKX internally or receive AHCLKX as an input. See Section 24.3.5.1.

Similarly, to receive data in the TDM transfer mode requires a minimum set of pins:

- ACLKR - receive bit clock.
- AFSR - receive frame sync (or commonly called left/right clock).
- One or more serial data pins, AXRn, whose serializers have been configured to receive.

The receiver has the option to receive the ACLKR bit clock as an input or to generate the ACLKR bit clock by dividing down the AHCLKR high-frequency master clock. The receiver can either generate AHCLKR internally or receive AHCLKR as an input. See Section 24.3.5.2 and Section 24.3.5.3.

The control registers must be configured as follows for the TDM mode. The TDM mode specific bit fields are in bold face:

- PFUNC: The clock, frame, data pins must be configured for McASP function.
- PDIR: The clock, frame, data pins must be configured to the direction desired.
- PDOUT, PDIN, PDSET, PDCLR: Not applicable. Leave at default.
- GBLCTL: Follow the initialization sequence in Section 24.3.12.2 to configure this register.
- AMUTE: Program all fields according to mute control desired.
- DLBCTL: If loopback mode is desired, configure this register according to Section 24.3.10.5, otherwise leave this register at default.
- DITCTL: DITEN must be left at default 0 to select TDM mode. Leave the register at default.
- RMASK/XMASK: Mask desired bits according to Section 24.3.9.2 and Section 24.3.10.3.
- RFMT/XFMT: Program all fields according to data format desired. See Section 24.3.10.3.
- AFSRCTL/AFSXCTL: Set **RMOD/XMOD** bits to 2-32 for TDM mode. Configure other fields as desired.
- ACLKRCTL/ACLKXCTL: Program all fields according to bit clock desired. See Section 24.3.5.
- AHCLKRCTL/AHCLKXCTL: Program all fields according to high-frequency clock desired. See Section 24.3.5.
- RTDM/XTDM: Program all fields according to the time slot characteristics desired.
- RINTCTL/XINTCTL: Program all fields according to interrupts desired.
- RCLKCHK/XCLKCHK: Program all fields according to clock checking desired.
- SRCTLn: Program all fields according to serializer operation desired.
- DITCSRA[n], DITCSRB[n], DITUDRA[n], DITUDRB[n]: Not applicable. Leave at default.

24.3.8.2.1 TDM Time Slots

TDM mode on the McASP can extend to support multiprocessor applications, with up to 32 time slots per frame. For each of the time slots, the McASP may be configured to participate or to be inactive by configuring XTDM and/or RTDM (this allows multiple processors to communicate on the same TDM serial bus).

The TDM sequencer (separate ones for transmit and receive) functions in this mode. The TDM sequencer counts the slots beginning with the frame sync. For each slot, the TDM sequencer checks the respective bit in either XTDM or RTDM to determine if the McASP should transmit/receive in that time slot.

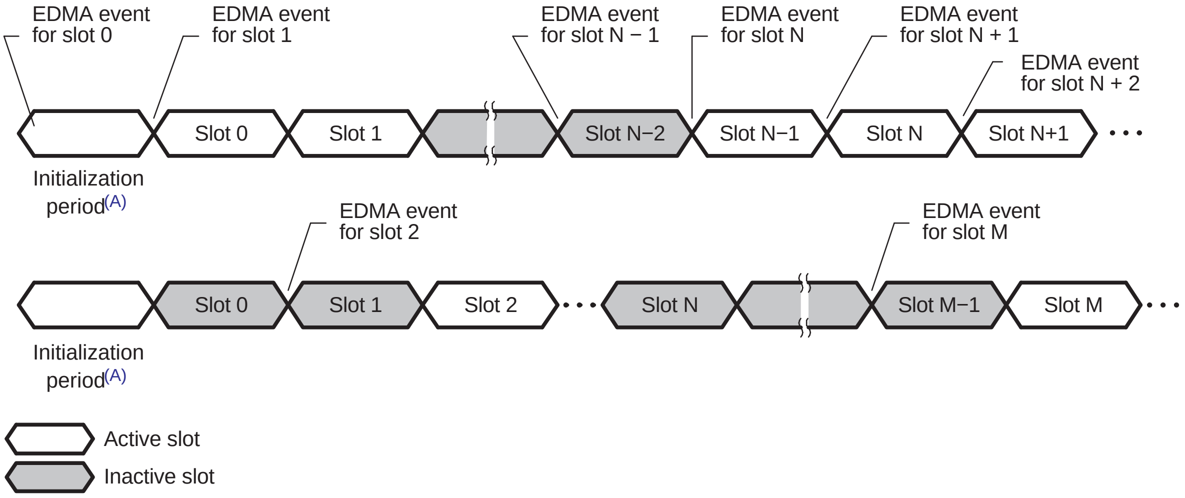
If the transmit/receive bit is active, the McASP functions normally during that time slot; otherwise, the McASP is inactive during that time slot; no update to the buffer occurs, and no event is generated. Transmit pins are automatically set to a high-impedance state, 0, or 1 during that slot, as determined by bit DISMOD in SRCTL[n].

Figure 24-21 shows when the transmit DMA event AXEVT is generated. See Section 24.3.10.1.1 for details on data ready and the initialization period indication. The transmit DMA event for an active time slot (slot N) is generated during the previous time slot (slot N - 1), regardless if the previous time slot (slot N - 1) is active or inactive.

During an active transmit time slot (slot N), if the next time slot (slot N + 1) is configured to be active, the copy from XRBUF[n] to XRSR[n] generates the DMA event for time slot N + 1. If the next time slot (slot N + 1) is configured to be inactive, then the DMA event will be delayed to time slot M - 1. In this case, slot M is the next active time slot. The DMA event for time slot M is generated during the first bit time of slot M - 1.

The receive DMA request generation does not need this capability, since the receive DMA event is generated after data is received in the buffer (looks back in time). If a time slot is disabled, then no data is copied to the buffer for that time slot and no DMA event is generated.

Figure 24-21. Transmit DMA Event (AXEVT) Generation in TDM Time Slots



A See Section 24.3.12.2, step 7a.

24.3.8.2.2 Special 384 Slot TDM Mode for Connection to External DIR

The McASP receiver also supports a 384 time slot TDM mode (DIR mode), to support S/PDIF, AES-3, IEC-60958 receiver ICs whose natural block (block corresponds to McASP frame) size is 384 samples. The advantage to using the 384 time slot TDM mode is that interrupts may be generated synchronous to the S/PDIF, AES-3, IEC-60958, such as the last slot interrupt.

The receive TDM time slot register (RTDM) should be programmed to all 1s during reception of a DIR block. Other TDM functionalities (for example, inactive slots) are not supported (only the slot counter counts the 384 subframes in a block).

To receive data in the DIR mode, the following pins are typically needed:

- ACLKR - receive bit clock.
- AFSR - receive frame sync (or commonly called left/right clock). In this mode, AFSR should be connected to a DIR which outputs a start of block signal, instead of LRCLK.
- One or more serial data pins, AXRn, whose serializers have been configured to receive.

For this special DIR mode, the control registers can be configured just as for TDM mode, except set RMOD in AFSRCTL to 384 to receive 384 time slots.

24.3.8.3 Digital Audio Interface Transmit (DIT) Transfer Mode

In addition to the TDM and burst transfer modes, which are suitable for transmitting audio data between ICs inside the same system, the digital audio interface transmit (DIT) transfer mode of the McASP also supports transmission of audio data in the S/PDIF, AES-3, or IEC-60958 format. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode only applies to serializers configured as transmitters, not receivers. See Section 24.3.3.2 for a description of the S/PDIF format.

24.3.8.3.1 Transmit DIT Encoding

The McASP operation in DIT mode is basically identical to the 2 time slot TDM mode, but the data transmitted is output as a biphase mark encoded bit stream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bit stream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

The transmit TDM time slot register (XTDM) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in the DIT mode, the following pins are typically needed:

- AHCLKX - transmit high-frequency master clock.
- One or more serial data pins, AXRn, whose serializers have been configured to transmit.

AHCLKX is optional (the internal clock source may be used instead), but if used as a reference, the processor provides a clock check circuit that continually monitors the AHCLKX input for stability.

If the McASP is configured to transmit in the DIT mode on more than one serial data pin, the bit streams on all pins will be synchronized. In addition, although they will carry unique audio data, they will carry the same channel status, user data, and validity information.

The actual 24-bit audio data must always be in bit positions 23-0 after passing through the first three stages of the transmit format unit.

For left-aligned Q31 data, the following transmit format unit settings process the data into right aligned 24-bit audio data ready for transmission:

- XROT = 010 (rotate right by 8 bits).
- XRVRS = 0 (no bit reversal, LSB first).
- XMASK = FFFF FF00h-FFFF 0000h (depending upon whether 24, 23, 22, 21, 20, 19, 18, 17, or 16 valid audio data bits are present).
- XPAD = 00 (pad extra bits with 0).

For right-aligned data, the following transmit format unit settings process the data into right aligned 24-bit audio data ready for transmission:

- XROT = 000 (rotate right by 0 bits).
- XRVRS = 0 (no bit reversal, LSB first).
- XMASK = 00FF FFFFh to 0000 FFFFh (depending upon whether 24, 23, 22, 21, 20, 19, 18, 17, or 16 valid audio data bits are present).
- XPAD = 00 (pad extra bits with 0).

24.3.8.3.2 Transmit DIT Clock and Frame Sync Generation

The DIT transmitter only works in the following configuration:

- In transmit frame control register (AFSXCTL):
  - Internally-generated transmit frame sync, FSXM = 1.
  - Rising-edge frame sync, FSXP = 0.
  - Bit-width frame sync, FXWID = 0.
  - 384-slot TDM, XMOD = 1 1000 0000b.
- In transmit clock control register (ACLKXCTL), ASYNC = 1.
- In transmit bitstream format register (XFMT), XSSZ = 1111 (32-bit slot size).

All combinations of AHCLKX and ACLKX are supported.

This is a summary of the register configurations required for DIT mode. The DIT mode specific bit fields are in bold face:

- PFUNC: The data pins must be configured for McASP function. If AHCLKX is used, it must also be configured for McASP function.
- PDIR: The data pins must be configured as outputs. If AHCLKX is used as an input reference, it should be configured as input. If internal clock source AUXCLK is used as the reference clock, it may be output on the AHCLKX pin by configuring AHCLKX as an output.
- PDOUT, PDIN, PDSET, PDCLR: Not applicable for DIT operation. Leave at default.
- GBLCTL: Follow the initialization sequence in Section 24.3.12.2 to configure this register.
- AMUTE: Program all fields according to mute control desired.
- DLBCTL: Not applicable. Loopback is not supported for DIT mode. Leave at default.
- DITCTL: **DITEN** bit must be set to 1 to enable DIT mode. Configure other bits as desired.
- RMASK: Not applicable. Leave at default.
- RFMT: Not applicable. Leave at default.
- AFSRCTL: Not applicable. Leave at default.
- ACLKRCTL: Not applicable. Leave at default.
- AHCLKRCTL: Not applicable. Leave at default.
- RTDM: Not applicable. Leave at default.
- RINTCTL: Not applicable. Leave at default.
- RCLKCHK: Not applicable. Leave at default.
- **XMASK**: Mask desired bits according to the discussion in this section, depending upon left-aligned or right-aligned internal data.

- **XFMT: XDATDLY** = 0. **XRVRS** = 0. **XPAD** = 0. **XPBIT** = default (not applicable). **XSSZ** = Fh (32-bit slot). XBUSEL = configured as desired. **XROT** bit is configured according to the discussion in this section, either 0 or 8-bit rotate.
- **AFSXCTL**: Configure the bits according to the discussion in this section.
- **ACLKXCTL**: **ASYNC** = 1. Program CLKXDIV bits to obtain the bit clock rate desired. Configure CLKXP and CLKXM bits as desired, because CLKX is not actually used in the DIT protocol.
- **AHCLKXCTL**: Program all fields according to high-frequency clock desired.
- **XTDM**: Set to FFFF FFFFh for all active slots for DIT transfers.
- XINTCTL: Program all fields according to interrupts desired.
- XCLKCHK: Program all fields according to clock checking desired.
- SRCTLn: Set **SRMOD** = 1 (transmitter) for the DIT pins. DISMOD field is don't care for DIT mode.
- **DITCSRA[n], DITCSRB[n]**: Program the channel status bits as desired.
- **DITUDRA[n], DITUDRB[n]**: Program the user data bits as desired.

24.3.8.3.3 DIT Channel Status and User Data Register Files

The channel status registers (DITCSRA*n* and DITCSRB*n*) and user data registers (DITUDRA*n* and DITUDRB*n*) are not double buffered. Typically the programmer uses one of the synchronizing interrupts, such as last slot, to create an event at a safe time so the register may be updated. In addition, the CPU reads the transmit TDM slot counter to determine which word of the register is being used.

It is a requirement that the software avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it will be indeterminate whether the old or new data is used to encode the bitstream.

The DIT subframe format is defined in Section 24.3.3.2.2. The channel status information (C) and User Data (U) are defined in these DIT control registers:

- DITCSRA0 to DITCSRA5: The 192 bits in these six registers contain the channel status information for the LEFT channel within each frame.
- DITCSRB0 to DITCSRB5: The 192 bits in these six registers contain the channel status information for the RIGHT channel within each frame.
- DITUDRA0 to DITUDRA5: The 192 bits in these six registers contain the user data information for the LEFT channel within each frame.
- DITUDRB0 to DITUDRB5: The 192 bits in these six registers contain the user data information for the RIGHT channel within each frame.

The S/PDIF block format is shown in Figure 24-13. There are 192 frames within a block (frame 0 to frame 191). Within each frame there are two subframes (subframe 1 and 2 for left and right channels, respectively). The channel status and user data information sent on each subframe is summarized in Table 24-8.

Table 24-8. Channel Status and User Data for Each DIT Block

Frame	Subframe	Preamble	Channel Status defined in:	User Data defined in:

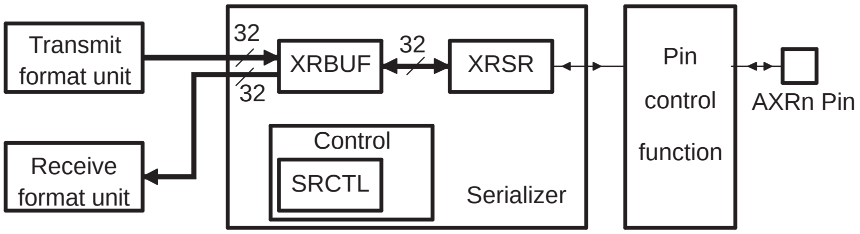
24.3.9 General Architecture

24.3.9.1 Serializers

Figure 24-22 shows the block diagram of the serializer and its interface to other units within the McASP. The serializers take care of shifting serial data in and out of the McASP. Each serializer consists of a shift register (XRSR), a data buffer (XRBUF), a control register (SRCTL), and logic to support the data alignment options of the McASP. For each serializer, there is a dedicated serial data pin (AXRn) and a dedicated control register (SRCTL[n]). The control register allows the serializer to be configured as a transmitter, receiver, or as inactive. When configured as a transmitter the serializer shifts out data to the serial data pin AXRn. When configured as a receiver, the serializer shifts in data from the AXRn pin. The serializer is clocked from the transmit/receive section clock (ACLKX/ACLKR) if configured to transmit/receive respectively.

All serializers that are configured to transmit operate in lock-step. Similarly, all serializers that are configured to receive also operate in lock-step. This means that at most there are two zones per McASP, one for transmit and one for receive.

Figure 24-22. Individual Serializer and Connections Within McASP



For receive, data is shifted in through the AXRn pin to the shift register XRSR. Once the entire slot of data is collected in the XRSR, the data is copied to the data buffer XRBUF. The data is now ready to be read by the processor through the RBUF register, which is an alias of the XRBUF for receive. When the processor reads from the RBUF, the McASP passes the data from RBUF through the receive format unit and returns the formatted data to the processor.

For transmit, the processor services the McASP by writing data into the XBUF register, which is an alias of the XRBUF for transmit. The data automatically passes through the transmit format unit before actually reaching the XRBUF register in the serializer. The data is then copied from XRBUF to XRSR, and shifted out from the AXRn synchronously to the serial clock.

In DIT mode, in addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.).

The serializer configuration is controlled by SRCTL[n].

24.3.9.2 Format Unit

The McASP has two data formatting units, one for transmit and one for receive. These units automatically remap the data bits within the transmitted and received words between a natural format for the processor (such as a Q31 representation) and the required format for the external serial device (such as "I2S format"). During the remapping process, the format unit also can mask off certain bits or perform sign extension.

Since all transmitters share the same data formatting unit, the McASP only supports one transmit format at a time. For example, the McASP will not transmit in "I2S format" on serializer 0, while transmitting "Left Justified" on serializer 1. Likewise, the receiver section of the McASP only supports one data format at a time, and this format applies to all receiving serializers. However, the McASP can transmit in one format while receiving in a completely different format.

This formatting unit consists of three stages:

- Bit mask and pad (masks off bits, performs sign extension)
- Rotate right (aligns data within word)
- Bit reversal (selects between MSB first or LSB first)

Figure 24-23 shows a block diagram of the receive formatting unit, and Figure 24-24 shows the transmit formatting unit. Note that the order in which data flows through the three stages is different between the transmit and receive formatting units.

Figure 24-23. Receive Format Unit

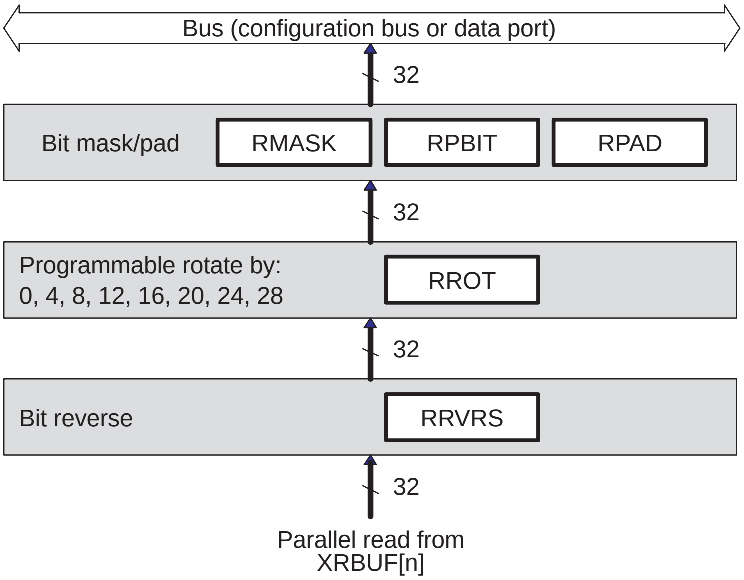


Figure 24-24. Transmit Format Unit

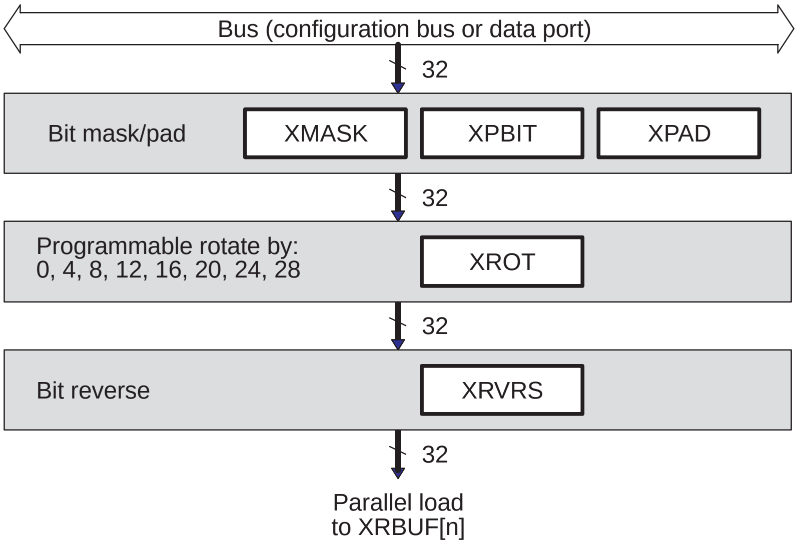


The bit mask and pad stage includes a full 32-bit mask register, allowing selected individual bits to either pass through the stage unchanged, or be masked off. The bit mask and pad then pad the value of the masked off bits by inserting either a 0, a 1, or one of the original 32 bits as the pad value. The last option allows for sign-extension when the sign bit is selected to pad the remaining bits.

The rotate right stage performs bitwise rotation by a multiple of 4 bits (between 0 and 28 bits), programmable by the (R/X)FMT register. Note that this is a rotation process, not a shifting process, so bit 0 gets shifted back into bit 31 during the rotation.

The bit reversal stage either passes all 32 bits directly through, or swaps them. This allows for either MSB or LSB first data formats. If bit reversal is not enabled, then the McASP will naturally transmit and receive in an LSB first order.

Finally, note that the (R/X)DATDLY bits in (R/X)FMT also determine the data format. For example, the difference between I2S format and left-justified is determined by the delay between the frame sync edge and the first data bit of a given time slot. For I2S format, (R/X)DATDLY should be set to a 1-bit delay, whereas for left-justified format, it should be set to a 0-bit delay.

The combination of all the options in (R/X)FMT means that the McASP supports a wide variety of data formats, both on the serial data lines, and in the internal processor representation.

Section 24.3.10.3 provides more detail and specific examples. The examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

24.3.9.3 State Machine

The receive and transmit sections have independent state machines. Each state machine controls the interactions between the various units in the respective section. In addition, the state machine keeps track of error conditions and serial port status.

No serial transfers can occur until the respective state machine is released from reset. See initialization sequence for details (Section 24.3.12).

The receive state machine is controlled by the RFMT register, and it reports the McASP status and error conditions in the RSTAT register. Similarly, the transmit state machine is controlled by the XFMT register, and it reports the McASP status and error conditions in the XSTAT register.

24.3.9.4 TDM Sequencer

There are separate TDM sequencers for the transmit section and the receive section. Each TDM sequencer keeps track of the slot count. In addition, the TDM sequencer checks the bits of (R/X)TDM and determines if the McASP should receive/transmit in that time slot.

If the McASP should participate (transmit/receive bit is active) in the time slot, the McASP functions normally. If the McASP should not participate (transmit/receive bit is inactive) in the time slot, no transfers between the XRBUF and XRSR registers in the serializer would occur during that time slot. In addition, the serializers programmed as transmitters place their data output pins in a predetermined state (logic low, high, or high impedance) as programmed by each serializer control register (SRCTL). Refer also to Section 24.3.8.2 for details on how DMA event or interrupt generations are handled during inactive time slots in TDM mode.

The receive TDM sequencer is controlled by register RTDM and reports current receive slot to RSLOT. The transmit TDM sequencer is controlled by register XTDM and reports current transmit slot to XSLOT.

24.3.9.5 Clock Check Circuit

A common source of error in audio systems is a serial clock failure due to instabilities in the off-chip DIR circuit. To detect a clock error quickly, a clock-check circuit is included in the McASP for both transmit and receive clocks, since both may be sourced from off chip.

The clock check circuit can detect and recover from transmit and receive clock failures. See Section 24.3.10.4.6 for implementation and programming details.

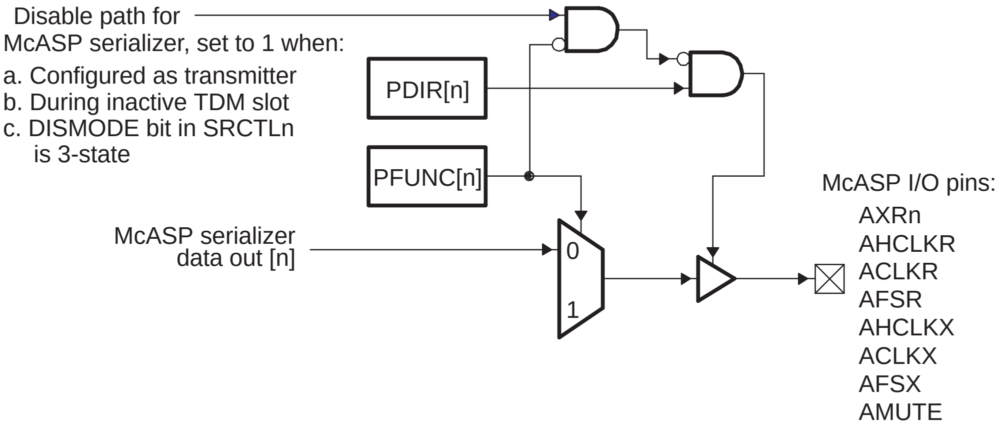
24.3.9.6 Pin Function Control

All McASP pins except AMUTEIN are bidirectional input/output pins. In addition, these bidirectional pins function either as McASP or general-purpose I/O (GPIO) pins. The following registers control the pin functions:

- Pin function register (PFUNC): selects pin to function as McASP or GPIO.
- Pin direction register (PDIR): selects pin to be input or output.
- Pin data input register (PDIN): shows data input at the pin.
- Pin data output register (PDOUT): data to be output at the pin if the pin is configured as GPIO output (PFUNC[n] = 1 and PDIR[n] = 1). Not applicable when the pin is configured as McASP pin (PFUNC[n] = 0).
- Pin data set register (PDSET): alias of PDOUT. Writing a 1 to PDSET[n] sets the respective PDOUT[n] to 1. Writing a 0 has no effect. Applicable only when the pin is configured as GPIO output (PFUNC[n] = 1 and PDIR[n] = 1).
- Pin data clear register (PDCLR): alias of PDOUT. Writing a 1 to PDCLR[n] clears the respective PDOUT[n] to 0. Writing a 0 has no effect. Applicable only when the pin is configured as GPIO output (PFUNC[n] = 1 and PDIR[n] = 1).

See the register descriptions in for details on the mapping of each McASP pin to the register bits. Figure 24-25 shows the pin control block diagram.

Figure 24-25. McASP I/O Pin Control Block Diagram



24.3.9.6.1 McASP Pin Control-Transmit and Receive

You must correctly set the McASP GPIO registers PFUNC and PDIR, even when McASP pins are used for their serial port (non-GPIO) function.

Serial port functions include:

- Clock pins (ACLKX, ACLKR, AHCLKX, AHCLKR, AFSX, AFSR) used as clock inputs and outputs.
- Serializer data pins (AXRn) used to transmit or receive.
- AMUTE used as a mute output signal.

When using these pins in their serial port function, you must clear PFUNC[n] to 0 for each pin.

Also, certain outputs require PDIR[n] = 1, such as clock pins used as clock outputs, serializer data pins used to transmit, and AMUTE used as mute output.

Clock inputs and serializers configured to receive must have PDIR[n] = 0.

PFUNC and PDIR do not control the AMUTEIN signal, it is usually tied to a device level interrupt pin (consult device datasheet). If used as a mute input, this pin needs to be configured as an input in the appropriate peripheral.

Finally, there is an important advantage to having separate control of pin direction (by PDIR), and the choice of internal versus external clocking (by CLKRM/CLKXM). Depending on the specific device and usage, you might select an external clock (CLKRM = 0), while enabling the internal clock divider, and the clock pin as an output in the PDIR register (PDIR[ACLKR] = 1). In this case, the bit clock is an output (PDIR[ACLKR] = 1) and, therefore, routed to the ACLKR pin. However, because CLKRM = 0, the bit clock is then routed back to the McASP module as an "external" clock source. This may result in less skew between the clock inside the McASP and the clock in the external device, thus producing more balanced setup and hold times for a particular system. As a result, this may allow a higher serial clock rate interface.

24.3.10 Operation

This section discusses the operation of the McASP.

24.3.10.1 Data Transmission and Reception

The processor services the McASP by writing data to the XBUF register(s) for transmit operations, and by reading data from the RBUF register(s) for receive operations. The McASP sets status flag and notifies the processor whenever data is ready to be serviced. Section 24.3.10.1.1 discusses data ready status in detail.

The XBUF and RBUF registers can be accessed through one of the two peripheral ports of the device:

- The data port (DAT): This port is dedicated for data transfers on the device.
- The configuration bus (CFG): This port is used for both data transfers and peripheral configuration control on the device.

Section 24.3.10.1.2 and Section 24.3.10.1.3 discuss how to perform transfers through the data port and the configuration bus.

Either the CPU or the DMA can be used to service the McASP through any of these two peripheral ports. The CPU and DMA usages are discussed in Section 24.3.10.1.4 and Section 24.3.14.2.

24.3.10.1.1 Data Ready Status and Event/Interrupt Generation

24.3.10.1.1.1 Transmit Data Ready

The transmit data ready flag XDATA bit in the XSTAT register reflects the status of the XBUF register. The XDATA flag is set when data is transferred from the XRBUF[n] buffers to the XRSR[n] shift registers, indicating that the XBUF is empty and ready to accept new data from the processor. This flag is cleared when the XDATA bit is written with a 1, or when all the serializers configured as transmitters are written by the processor.

Whenever XDATA is set, an DMA event AXEVT is automatically generated to notify the DMA of the XBUF empty status. An interrupt AXINT is also generated if XDATA interrupt is enabled in the XINTCTL register (See Section 24.3.13.2 for details).

For DMA requests, the McASP does not require XSTAT to be read between DMA events. This means that even if XSTAT already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

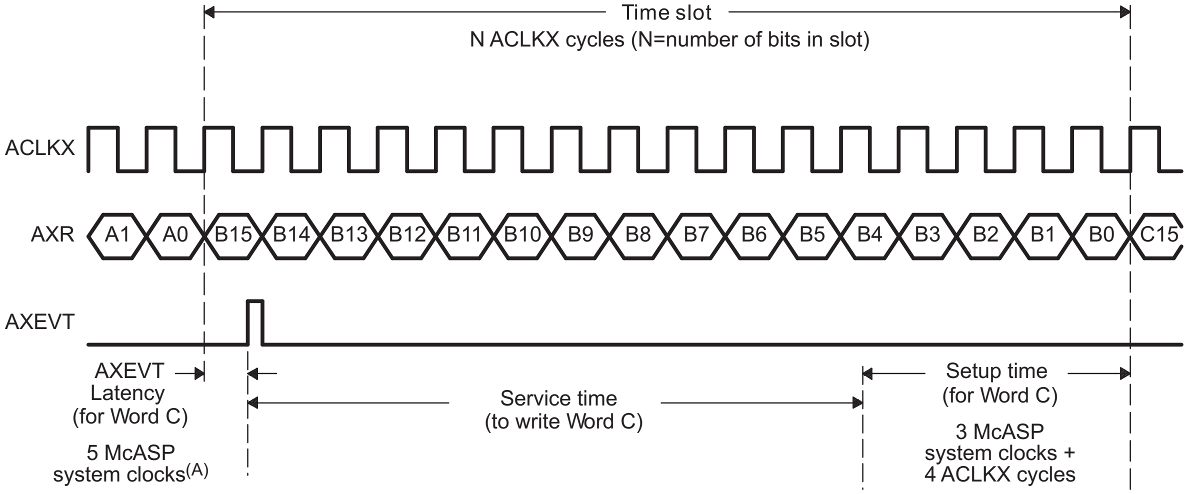
Since all serializers act in lockstep, only one DMA event is generated to indicate that all active transmit serializers are ready to be written to with new data.

Figure 24-26 shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to 5 McASP system clocks (AXEVT Latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the processor can begin servicing the McASP by writing Word C into the XBUF (Processor Service Time). The processor must write Word C into the XBUF no later than the setup time required by the McASP (Setup Time).

The maximum Processor Service Time (Figure 24-26) can be calculated as:

Processor Service Time = Time Slot - AXEVT Latency - Setup Time

Figure 24-26. Processor Service Time Upon Transmit DMA Event (AXEVT)



A Refer to the device-specific data manual for the McASP system clock source. This is not the same as AUXCLK.

Example 24-1. Processor Service Time Calculation for Transmit DMA Event (AXEVT)

The following is an example to show how to calculate Processor Service Time. Assume the following setup:

- McASP transmits in I2S format at 192 kHz frame rate. Assume slot size is 32 bit.

With the above setup, we obtain the following parameters corresponding to Figure 24-26:

- Calculation of McASP system clock cycle:
  - System functional clock = 26 MHz
  - Therefore, McASP system clock cycle = 1/26MHz = 38.5 ns.
- Calculation of ACLKX clock cycle:
  - This example has two 32-bit slots per frame, for a total of 64 bits per frame.
  - ACLKX clock cycle is (1/192 kHz)/64 = 81.4 ns.
- Time Slot between AXEVT events:
  - For I2S format, McASP generates two AXEVT events per 192 kHz frame.
  - Therefore, Time Slot between AXEVT events is (1/192 kHz)/2 = 2604 ns.
- AXEVT Latency:
  = 5 McASP system clocks
  = 38.5 ns × 5 = 192.5 ns
- Setup Time
  = 3 McASP system clocks + 4 ACLKX cycles
  = (38.5 ns × 3) + (81.4 ns × 4)
  = 441.1 ns
- Processor Service Time
  = Time Slot - AXEVT Latency - Setup Time
  = 2604 ns - 441.1 ns - 192.5 ns
  = 1970.4 ns

24.3.10.1.1.2 Receive Data Ready

Similarly, the receive data ready flag RDATA bit in the RSTAT reflects the status of the RBUF register. The RDATA flag is set when data is transferred from the XRSR[n] shift registers to the XRBUF[n] buffers, indicating that the RBUF contains received data and is ready to have the processor read the data. This flag is cleared when the RDATA bit is written with a 1, or when all the serializers configured as receivers are read.

Whenever RDATA is set, an DMA event AREVT is automatically generated to notify the DMA of the RBUF ready status. An interrupt ARINT is also generated if RDATA interrupt is enabled in the RINTCTL register (See Section 24.3.13.3 for details).

For DMA requests, the McASP does not require RSTAT to be read between DMA events. This means that even if RSTAT already has the RDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

Since all serializers act in lockstep, only one DMA event is generated to indicate that all active receive serializers are ready to receive new data.

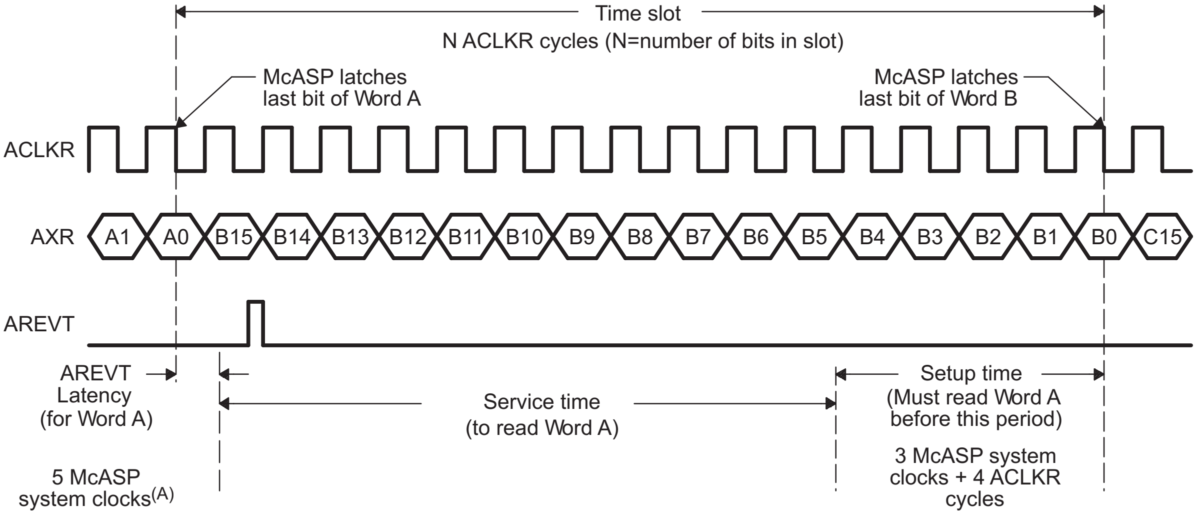
Figure 24-27 shows the timing details of when AREVT is generated at the McASP boundary. In this example, as soon as the last bit (bit A0) of Word A is received, the McASP sets the RDATA flag and generates an AREVT event. However, it takes up to 5 McASP system clocks (AREVT Latency) before AREVT is active at the McASP boundary. Upon AREVT, the processor can begin servicing the McASP by reading Word A from the RBUF (Processor Service Time). The processor must read Word A from the XBUF no later than the setup time required by the McASP (Setup Time).

The maximum Processor Service Time (Figure 24-27) can be calculated as:

Processor Service Time = Time Slot - AREVT Latency - Setup Time

The Processor Service Time calculation for receive is similar to the calculation for transmit. See Example 24-1 for Processor Service Time calculation using transmit as an example.

Figure 24-27. Processor Service Time Upon Receive DMA Event (AREVT)



A The device uses SYSCLK2 as the McASP system clock source.

24.3.10.1.2 Transfers Through the Data Port (DAT)

NOTE: To perform internal transfers through the data port, clear XBUSEL/RBUSEL bit to 0 in the respective XFMT/RFMT registers. Failure to do so will result in software malfunction.

Typically, you will access the McASP XRBUF registers through the data port. To access through the data port, simply have the CPU or DMA access the XRBUF through its data port location. Through the data port, the DMA/CPU can service all the serializers through a single address. The McASP automatically cycles through the appropriate serializers.

For transmit operations through the data port, the DMA/CPU should write to the same XBUF data port address to service all of the active transmit serializers. In addition, the DMA/CPU should write to the XBUF for all active transmit serializers in incremental (although not necessarily consecutive) order. For example, if serializers 0, 4, and 5, are set up as active transmitters, the DMA/CPU should write to the XBUF data port address four times with data for serializers 0, 4, and 5, upon each transmit data ready event. This exact servicing order must be followed so that data appears in the appropriate serializers.

Similarly, for receive operations through the data port, the DMA/CPU should read from the same RBUF data port address to service all of the active receive serializers. In addition, reads from the active receive serializers through the data port return data in incremental (although not necessarily consecutive) order. For example, if serializers 1, 2, and 3, are set up as active receivers, the DMA/CPU should read from the RBUF data port address four times to obtain data for serializers 1, 2, and 3, in this exact order, upon each receive data ready event.

When transmitting, the DMA/CPU must write data to each serializer configured as "active" and "transmit" within each time slot. Failure to do so results in a buffer underrun condition (Section 24.3.10.4.2). Similarly, when receiving, data must be read from each serializer configured as "active" and "receive" within each time slot. Failure to do results in a buffer overrun condition (Section 24.3.10.4.3).

To perform internal transfers through the data port, clear XBUSEL/RBUSEL bit to 0 in the respective XFMT/RFMT registers.

24.3.10.1.3 Transfers Through the Configuration Bus (CFG)

NOTE: To perform internal transfers through the configuration bus, set XBUSEL/RBUSEL bit to 1 in the respective XFMT/RFMT registers. Failure to do so will result in software malfunction.

In this method, the DMA/CPU accesses the XRBUF registers through the configuration bus address. The exact XRBUF register address for any particular serializer is determined by adding the offset for that particular serializer to the base address for the particular McASP. XRBUF for the serializers configured as transmitters is given the name XBUF*n*. For example, the XRBUF associated with transmit serializer 2 is named XBUF2. Similarly, XRBUF for the serializers configured as receivers is given the name RBUF*n*.

Accessing the XRBUF registers through the data port is different because the CPU/DMA only needs to access one single address. When accessing through the configuration bus, the CPU/DMA must provide the exact XBUF*n* or RBUF*n* address for each access.

When transmitting, DMA/CPU must write data to each serializer configured as "active" and "transmit" within each time slot. Failure to do so results in a buffer underrun condition (Section 24.3.10.4.2). Similarly when receiving, data must be read from each serializer configured as "active" and "receive" within each time slot. Failure to do results in a buffer overrun condition (Section 24.3.10.4.3).

To perform internal transfers through the configuration bus, set XBUSEL/RBUSEL bit to 1 in the respective XFMT/RFMT registers.

24.3.10.1.4 Using the CPU for McASP Servicing

The CPU can be used to service the McASP through interrupt (upon AXINT/ARINT interrupts) or through polling the XDATA bit in the XSTAT register. As discussed in Section 24.3.10.1.2 and Section 24.3.10.1.3, the CPU can access through either the data port or through the configuration bus.

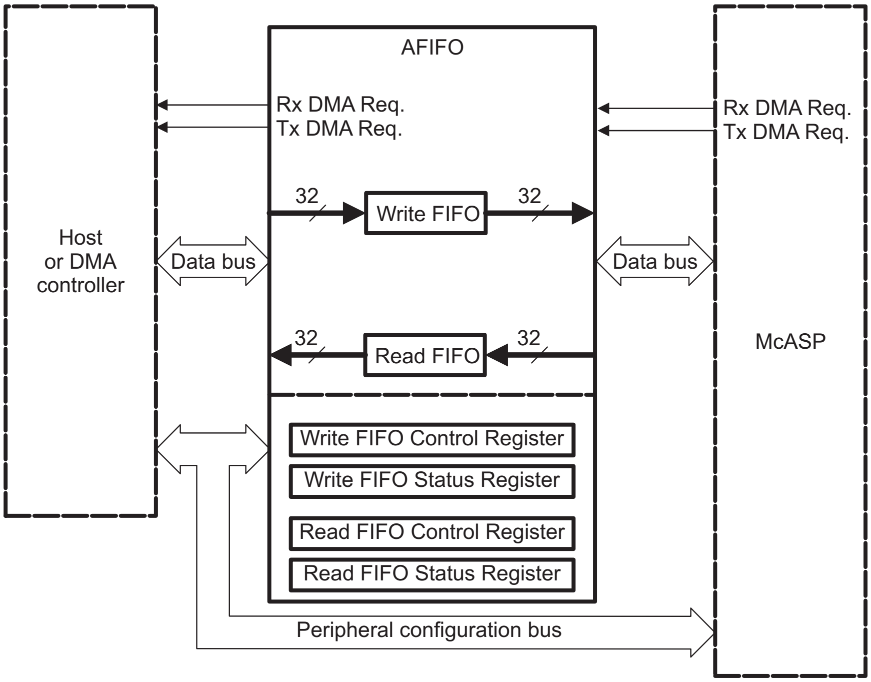
To use the CPU to service the McASP through interrupts, the XDATA/RDATA bit must be enabled in the respective XINTCTL/RINTCTL registers, to generate interrupts AXINT/ARINT to the CPU upon data ready.

24.3.10.2 McASP Audio FIFO (AFIFO)

The AFIFO contains two FIFOs: one Read FIFO (RFIFO), and one Write FIFO (WFIFO). To ensure backward compatibility with existing software, both the Read and Write FIFOs are disabled by default. See Figure 24-28 for a high-level block diagram of the AFIFO.

The AFIFO may be enabled/disabled and configured via the WFIFOCTL and RFIFOCTL registers. Note that if the Read or Write FIFO is to be enabled, it must be enabled prior to initializing the receive/transmit section of the McASP (see Section 24.3.12.2 for details).

Figure 24-28. McASP Audio FIFO (AFIFO) Block Diagram



24.3.10.2.1 AFIFO Data Transmission

When the Write FIFO is disabled, transmit DMA requests pass through directly from the McASP to the host/DMA controller. Whether the WFIFO is enabled or disabled, the McASP generates transmit DMA requests as needed; the AFIFO is “invisible” to the McASP.

When the Write FIFO is enabled, transmit DMA requests from the McASP are sent to the AFIFO, which in turn generates transmit DMA requests to the host/DMA controller.

If the Write FIFO is enabled, upon a transmit DMA request from the McASP, the WFIFO writes *WNUMDMA* 32-bit words to the McASP if and when there are at least *WNUMDMA* words in the Write FIFO. If there are not, the WFIFO waits until this condition has been satisfied. At that point, it writes *WNUMDMA* words to the McASP. (See description for WFIFOCTL.WNUMDMA.)

If the host CPU writes to the Write FIFO, independent of a transmit DMA request, the WFIFO will accept host writes until full. After this point, excess data will be discarded.

Note that when the WFIFO is first enabled, it will immediately issue a transmit DMA request to the host. This is because it begins in an empty state, and is therefore ready to accept data.

24.3.10.2.1.1 Transmit DMA Event Pacer

The AFIFO may be configured to delay making a transmit DMA request to the host until the Write FIFO has enough space for a specified number of words. In this situation, the number of transmit DMA requests to the host or DMA controller is reduced.

If the Write FIFO has space to accept *WNUMEVT* 32-bit words, it generates a transmit DMA request to the host and then waits for a response. Once *WNUMEVT* words have been written to the FIFO, it checks again to see if there is space for *WNUMEVT* 32-bit words. If there is space, it generates another transmit DMA request to the host, and so on. In this fashion, the Write FIFO will attempt to stay filled.

Note that if transmit DMA event pacing is desired, WFIFOCTL.WNUMEVT should be set to a non-zero integer multiple of the value in WFIFOCTL.WNUMDMA. If transmit DMA event pacing is not desired, then the value in WFIFOCTL.WNUMEVT should be set equal to the value in WFIFOCTL.WNUMDMA.

24.3.10.2.2 AFIFO Data Reception

When the Read FIFO is disabled, receive DMA requests pass through directly from McASP to the host/DMA controller. Whether the RFIFO is enabled or disabled, the McASP generates receive DMA requests as needed; the AFIFO is “invisible” to the McASP.

When the Read FIFO is enabled, receive DMA requests from the McASP are sent to the AFIFO, which in turn generates receive DMA requests to the host/DMA controller.

If the Read FIFO is enabled and the McASP makes a receive DMA request, the RFIFO reads *RNUMDMA* 32-bit words from the McASP, if and when the RFIFO has space for *RNUMDMA* words. If it does not, the RFIFO waits until this condition has been satisfied; at that point, it reads *RNUMDMA* words from the McASP. (See description for RFIFOCTL.RNUMDMA.)

If the host CPU reads the Read FIFO, independent of a receive DMA request, and the RFIFO at that time contains less than *RNUMEVT* words, those words will be read correctly, emptying the FIFO.

24.3.10.2.2.1 Receive DMA Event Pacer

The AFIFO may be configured to delay making a receive DMA request to the host until the Read FIFO contains a specified number of words. In this situation, the number of receive DMA requests to the host or DMA controller is reduced.

If the Read FIFO contains at least *RNUMEVT* 32-bit words, it generates a receive DMA request to the host and then waits for a response. Once *RNUMEVT* 32-bit words have been read from the RFIFO, the RFIFO checks again to see if it contains at least another *RNUMEVT* words. If it does, it generates another receive DMA request to the host, and so on. In this fashion, the Read FIFO will attempt to stay empty.

Note that if receive DMA event pacing is desired, RFIFOCTL.RNUMEVT should be set to a non-zero integer multiple of the value in RFIFOCTL.RNUMDMA. If receive DMA event pacing is not desired, then the value in RFIFOCTL.RNUMEVT should be set equal to the value in RFIFOCTL.RNUMDMA.

24.3.10.2.3 Arbitration Between Transmit and Receive DMA Requests

If both the WFIFO and the RFIFO are enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete.

If only the WFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the transmit DMA request. Once a transfer is in progress, it is allowed to complete.

If only the RFIFO is enabled and a transmit DMA request and receive DMA request occur simultaneously, priority is given to the receive DMA request. Once a transfer is in progress, it is allowed to complete.

24.3.10.3 Formatter

24.3.10.3.1 Transmit Bit Stream Data Alignment

The McASP transmitter supports serial formats of:

- Slot (or Time slot) size = 8, 12, 16, 20, 24, 28, 32 bits.
- Word size ≤ Slot size.
- Alignment: when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad.
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot.
- Order: order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB.
  - LSB: least-significant bit of word is shifted out last, last bit is MSB.

Hardware support for these serial formats comes from the programmable options in the transmit bitstream format register (XFMT):

- XRVRS: bit reverse (1) or no bit reverse (0).
- XROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits.
- XSSZ: transmit slot size of 8, 12, 16, 20, 24, 28, or 32 bits.

XSSZ should always be programmed to match the slot size of the serial stream. The word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the XROT field.

Table 24-9 and Figure 24-29 show the XRVRS and XROT fields for each serial format and for both integer and Q31 fractional internal representations.

This discussion assumes that all slot size (SLOT in Table 24-9) and word size (WORD in Table 24-9) options are multiples of 4, since the transmit rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The transmit bit mask/pad unit operates on data as an initial step of the transmit format unit (see Figure 24-24), and the data is aligned in the same representation as it is written to the transmitter by the processor (typically Q31 or integer).

Table 24-9. Transmit Bitstream Data Alignment

Figure 24-29	Bit Stream Order	Bit Stream Alignment	Internal Numeric Representation	XFMT Bit	
				XROT[1]	XRVRS
(a)[2]	MSB first	Left aligned	Q31 fraction	0	1
(b)	MSB first	Right aligned	Q31 fraction	SLOT - WORD	1
(c)	LSB first	Left aligned	Q31 fraction	32 - WORD	0
(d)	LSB first	Right aligned	Q31 fraction	32 - SLOT	0
(e)[2]	MSB first	Left aligned	Integer	WORD	1
(f)	MSB first	Right aligned	Integer	SLOT	1
(g)	LSB first	Left aligned	Integer	0	0
(h)	LSB first	Right aligned	Integer	(32 - (SLOT - WORD)) % 32	0

[1] WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

[2] To transmit in I2S format, use MSB first, left aligned, and also select XDATDLY = 01 (1 bit delay)

24.3.10.3.2 Receive Bit Stream Data Alignment

The McASP receiver supports serial formats of:

- Slot or time slot size = 8, 12, 16, 20, 24, 28, 32 bits.
- Word size ≤ Slot size.
- Alignment when more bits/slot than bits/words, then:
  - Left aligned = word shifted first, remaining bits are pad.
  - Right aligned = pad bits are shifted first, word occupies the last bits in slot.
- Order of bits shifted out:
  - MSB: most-significant bit of word is shifted out first, last bit is LSB.
  - LSB: least-significant bit of word is shifted out last, last bit is MSB.

Hardware support for these serial formats comes from the programmable options in the receive bitstream format register (RFMT):

- RRVRS: bit reverse (1) or no bit reverse (0).
- RROT: rotate right by 0, 4, 8, 12, 16, 20, 24, or 28 bits.
- RSSZ: receive slot size of 8, 12, 16, 20, 24, 28, or 32 bits.

RSSZ should always be programmed to match the slot size of the serial stream. The word size is not directly programmed into the McASP, but rather is used to determine the rotation needed in the RROT field.

Table 24-10 and Figure 24-30 show the RRVRS and RROT fields for each serial format and for both integer and Q31 fractional internal representations.

This discussion assumes that all slot size and word size options are multiples of 4; since the receive rotate right unit only supports rotation by multiples of 4. However, the bit mask/pad unit does allow for any number of significant digits. For example, a Q31 number may have 19 significant digits (word) and be transmitted in a 24-bit slot; this would be formatted as a word size of 20 bits and a slot size of 24 bits. However, it is possible to set the bit mask unit to only pass the 19 most-significant digits (program the mask value to FFFF E000h). The digits that are not significant can be set to a selected pad value, which can be any one of the significant digits, a fixed value of 0, or a fixed value of 1.

The receive bit mask/pad unit operates on data as the final step of the receive format unit (see Figure 24-23), and the data is aligned in the same representation as it is read from the receiver by the processor (typically Q31 or integer).

Table 24-10. Receive Bitstream Data Alignment

				RFMT Bit	
Figure 24-30	**Bit Stream Order**	**Bit Stream Alignment**	**Internal Numeric Representation**	**RROT**[1]	**RRVRS**
(a)[2]	MSB first	Left aligned	Q31 fraction	SLOT	1
(b)	MSB first	Right aligned	Q31 fraction	WORD	1
(c)	LSB first	Left aligned	Q31 fraction	(32 - (SLOT - WORD)) % 32	0
(d)	LSB first	Right aligned	Q31 fraction	0	0
(e)[2]	MSB first	Left aligned	Integer	SLOT - WORD	1
(f)	MSB first	Right aligned	Integer	0	1
(g)	LSB first	Left aligned	Integer	32 - SLOT	0
(h)	LSB first	Right aligned	Integer	32 - WORD	0

[1] WORD = Word size rounded up to the nearest multiple of 4; SLOT = slot size; % = modulo operator

[2] To transmit in I2S format, select MSB first, left aligned, and also select RDATDLY = 01 (1 bit delay)

24.3.10.4 Error Handling and Management

To support the design of a robust audio system, the McASP includes error-checking capability for the serial protocol, data underrun, and data overrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX/AHCLKR clock cycles. The timer value can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

Upon the detection of any one or more errors (software selectable), or the assertion of the AMUTEIN input pin, the AMUTE output pin may be asserted to a high or low level to immediately mute the audio output. In addition, an interrupt may be generated if desired, based on any one or more of the error sources.

24.3.10.4.1 Unexpected Frame Sync Error

An unexpected frame sync occurs when:

- In burst mode, when the next active edge of the frame sync occurs early such that the current slot will not be completed by the time the next slot is scheduled to begin.
- In TDM mode, a further constraint is that the frame sync must occur exactly during the correct bit clock (not a cycle earlier or later) and only before slot 0. An unexpected frame sync occurs if this condition is not met.

When an unexpected frame sync occurs, there are two possible actions depending upon when the unexpected frame sync occurs:

1. Early: An early unexpected frame sync occurs when the McASP is in the process of completing the current frame and a new frame sync is detected (not including overlap that occurs due to a 1 or 2 bit frame sync delay). When an early unexpected frame sync occurs:
   - Error interrupt flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
   - Current frame is not resynchronized. The number of bits in the current frame is completed. The next frame sync, which occurs after the current frame is completed, will be resynchronized.
2. Late: A late unexpected frame sync occurs when there is a gap or delay between the last bit of the previous frame and the first bit of the next frame. When a late unexpected frame sync occurs (as soon as the gap is detected):
   - Error interrupt flag is set (XSYNCERR, if an unexpected transmit frame sync occurs; RSYNCERR, if an unexpected receive frame sync occurs).
   - Resynchronization occurs upon the arrival of the next frame sync.

Late frame sync is detected the same way in both burst mode and TDM mode; however, in burst mode, late frame sync is not meaningful and its interrupt enable should not be set.

24.3.10.4.2 Buffer Underrun Error - Transmitter

A buffer underrun can only occur for serializers programmed to be transmitters. A buffer underrun occurs when the serializer is instructed by the transmit state machine to transfer data from XRBUF[n] to XRSR[n], but XRBUF[n] has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the processor explicitly writes a 1 to the XUNDRN bit to clear the XUNDRN bit.

In DIT mode, a pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 × fs). By shifting out a pair of zeros, a clock may be recovered on the receiver. To recover, reset the McASP and start again with the proper initialization.

In TDM mode, during an underrun case, a long stream of zeros are shifted out causing the DACs to mute. To recover, reset the McASP and start again with the proper initialization.

24.3.10.4.3 Buffer Overrun Error - Receiver

A buffer overrun can only occur for serializers programmed to be receivers. A buffer overrun occurs when the serializer is instructed to transfer data from XRSR[n] to XRBUF[n], but XRBUF[n] has not yet been read by either the DMA or the processor. When this occurs, the receiver state machine sets the ROVRN flag. However, the individual serializer writes over the data in the XRBUF[n] register (destroying the previous sample) and continues shifting.

An overrun is checked only once per time slot. The ROVRN flag is set when an overrun condition occurs. It is possible that an overrun occurs on one time slot but then the processor catches up and does not cause an overrun on the following time slots. However, once the ROVRN flag is set, it remains set until the processor explicitly writes a 1 to the ROVRN bit to clear the ROVRN bit.

24.3.10.4.4 DMA Error - Transmitter

A transmit DMA error, as indicated by the XDMAERR flag in the XSTAT register, occurs when the DMA (or CPU) writes more words to the DAT port of the McASP than it should. For each DMA event, the DMA should write exactly as many words as there are serializers enabled as transmitters.

XDMAERR indicates that the DMA (or CPU) wrote too many words to the McASP for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in XSTAT.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or CPU. You should reinitialize both the McASP transmitter and the DMA to resynchronize them.

24.3.10.4.5 DMA Error - Receiver

A receive DMA error, as indicated by the RDMAERR flag in the RSTAT register, occurs when the DMA (or CPU) reads more words from the DAT port of the McASP than it should. For each DMA event, the DMA should read exactly as many words as there are serializers enabled as receivers.

RDMAERR indicates that the DMA (or CPU) read too many words from the McASP for a given receive DMA event. Reading too few words results in a receiver overrun error setting ROVRN in RSTAT.

While RDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA or CPU. You should reinitialize both the McASP receiver and the DMA to resynchronize them.

24.3.10.4.6 Clock Failure Detection

24.3.10.4.6.1 Clock-Failure Check Startup

It is expected, initially, that the clock-failure circuits will generate an error until at least one measurement has been taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not immediately be enabled, but be enabled only after a specific startup procedure. The startup procedure is:

1. For the transmit clock failure check:
   a. Configure transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (XCLKCHK).
   b. Clear transmit clock failure flag (XCKFAIL) in the transmit status register (XSTAT).
   c. Wait until first measurement is taken (> 32 AHCLKX clock periods).
   d. Verify no clock failure is detected.
   e. Repeat steps b–d until clock is running and is no longer issuing clock failure errors.
   f. After the transmit clock is measured and falls within the acceptable range, the following may be enabled:
      i. transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (XINTCTL).
      ii. transmit clock failure detect autoswitch enable bit (XCKFAILSW) in the transmit clock check control register (XCLKCHK).
      iii. mute option (XCKFAIL) in the mute control register (AMUTE).
2. For the receive clock failure check:
   a. Configure receive clock failure detect logic (RMIN, RMAX, RPS) in the receive clock check control register (RCLKCHK).
   b. Clear receive clock failure flag (RCKFAIL) in the receive status register (RSTAT).
   c. Wait until first measurement is taken (> 32 AHCLKR clock periods).
   d. Verify no clock failure is detected.
   e. Repeat steps b–d until clock is running and is no longer issuing clock failure errors.
   f. After the receive clock is measured and falls within the acceptable range, the following may be enabled:
      i. receive clock failure interrupt enable bit (RCKFAIL) in the receiver interrupt control register (RINTCTL).
      ii. mute option (RCKFAIL) in the mute control register (AMUTE).

24.3.10.4.6.2 Transmit Clock Failure Check and Recovery

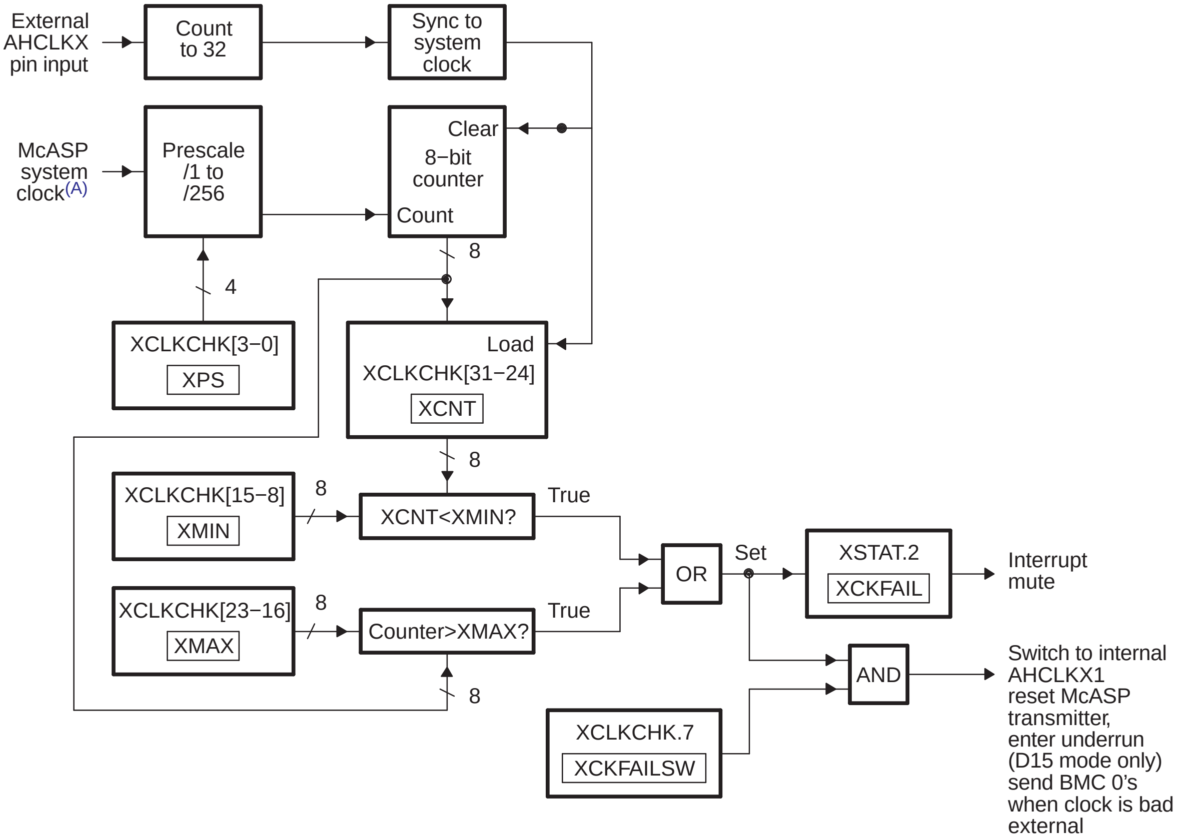
The transmit clock failure check circuit (Figure 24-31) works off both the internal McASP system clock and the external high-frequency serial clock (AHCLKX). It continually counts the number of system clocks for every 32 high rate serial clock (AHCLKX) periods, and stores the count in XCNT of the transmit clock check control register (XCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in XSTST) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than XMIN. The logic continually compares the current count (from the running system clock counter) against the maximum allowable boundary (XMAX). This is in case the external clock completely stops, so that the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. Note that the XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected, or that the audio source has changed and a new sample rate is being used.

In order for the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset regardless if AHCLKX is internally generated or externally sourced.

Figure 24-31. Transmit Clock Failure Detection Circuit Block Diagram



A Refer to device data manual for the McASP system clock source. This is not the same as AUXCLK.

The following actions are taken if a clock failure is detected:

1. Transmit clock failure flag (XCKFAIL) in XSTAT is set. This causes an interrupt if transmit clock failure interrupt enable bit (XCKFAIL) in XINTCTL is set.

In addition (only supported for DIT mode), if the transmit clock failure detect autoswitch enable bit (XCKFAILSW) in XCLKCHK is set, the following additional steps are taken to change the clock source from external to internal:

1. High-frequency transmit clock source bit (HCLKXM) in AHCLKXCTL is set to 1 and internal serial clock divider is selected. However, AHCLKX pin direction does not change to an output while XCKFAIL is set.
2. The internal clock divider is reset, so that the next clock it produces is a full period. However, the transmit clock divide ratio bits (HCLKXDIV) in AHCLKXCTL are not affected, so the internal clock divider generates clocks at the rate configured.
3. The transmit section is reset for a single serial clock period.
4. The transmit section is released from reset and attempts to begin transmitting. If data is available, it begins transmitting immediately; otherwise, it enters the underrun state. An initial underrun is certain to occur, the pattern 1100 (BMC zeroes) should be shifted out initially.

To change back to an external clock, take the following actions:

1. Wait for the external clock to stabilize again. This can be checked by polling the transmit clock count (XCNT) in XCLKCHK.
2. Reset the transmit section according to the startup procedure in Section 24.3.10.4.6.1.

24.3.10.4.6.3 Receive Clock Failure Check and Recovery

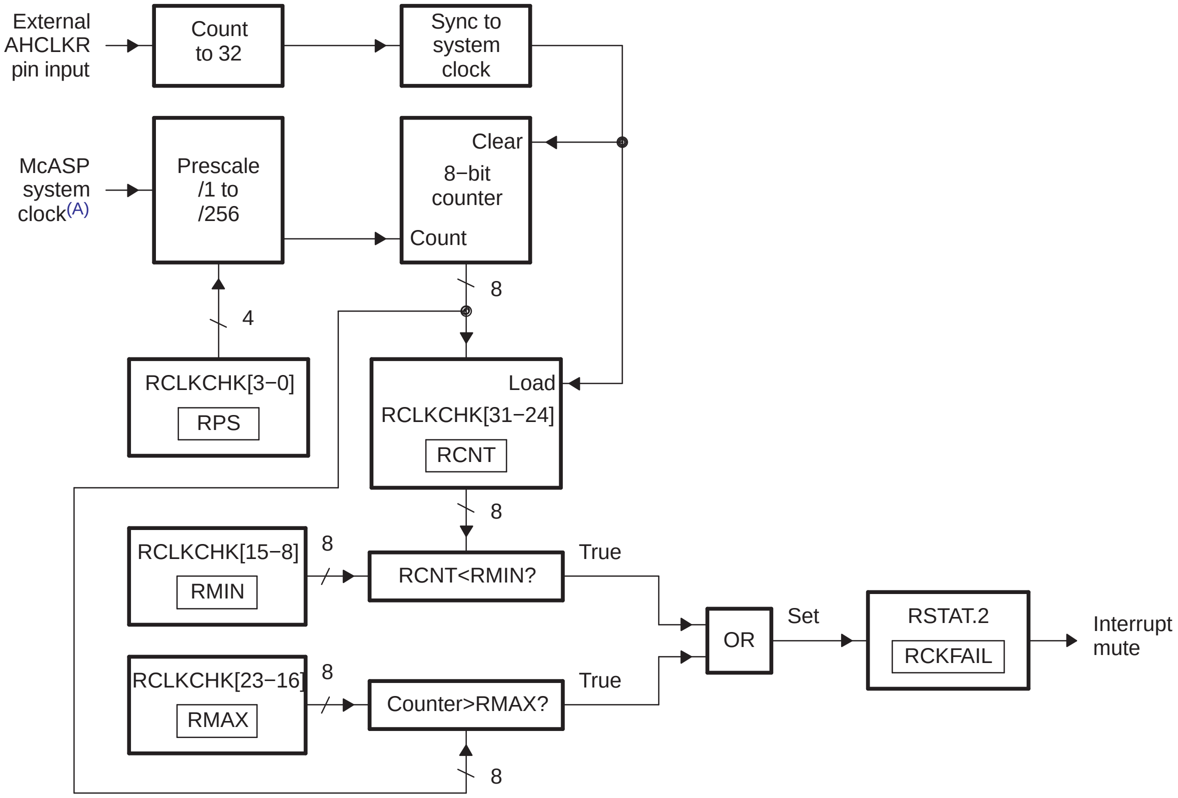
The receive clock failure check circuit (Figure 24-32) works off both the internal McASP system clock and the external high-frequency serial clock (AHCLKR). It continually counts the number of system clocks for every 32 high rate serial clock (AHCLKR) periods, and stores the count in RCNT of the receive clock check control register (RCLKCHK) every 32 high rate serial clock cycles.

The logic compares the count against a user-defined minimum allowable boundary (RMIN) and automatically flags an interrupt (RCKFAIL in RSTAT) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is smaller than RMIN. The logic continually compares the current count (from the running system clock counter) against the maximum allowable boundary (RMAX). This is in case the external clock completely stops, so that the counter value is not copied to RCNT. An out-of-range maximum condition occurs when the count is greater than RMAX. Note that the RMIN and RMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate either that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

In order for the receive clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset regardless if AHCLKR is internally generated or externally sourced.

Figure 24-32. Receive Clock Failure Detection Circuit Block Diagram



A Refer to device data manual for the McASP system clock source. This is not the same as AUXCLK.

24.3.10.5 Loopback Modes

The McASP features a digital loopback mode (DLB) that allows testing of the McASP code in TDM mode with a single processor device. In loopback mode, output of the transmit serializers is connected internally to the input of the receive serializers. Therefore, you can check the receive data against the transmit data to ensure that the McASP settings are correct. Digital loopback mode applies to TDM mode only (2 to 32 slots in a frame). It does not apply to DIT mode (XMOD = 180h) or burst mode (XMOD = 0).

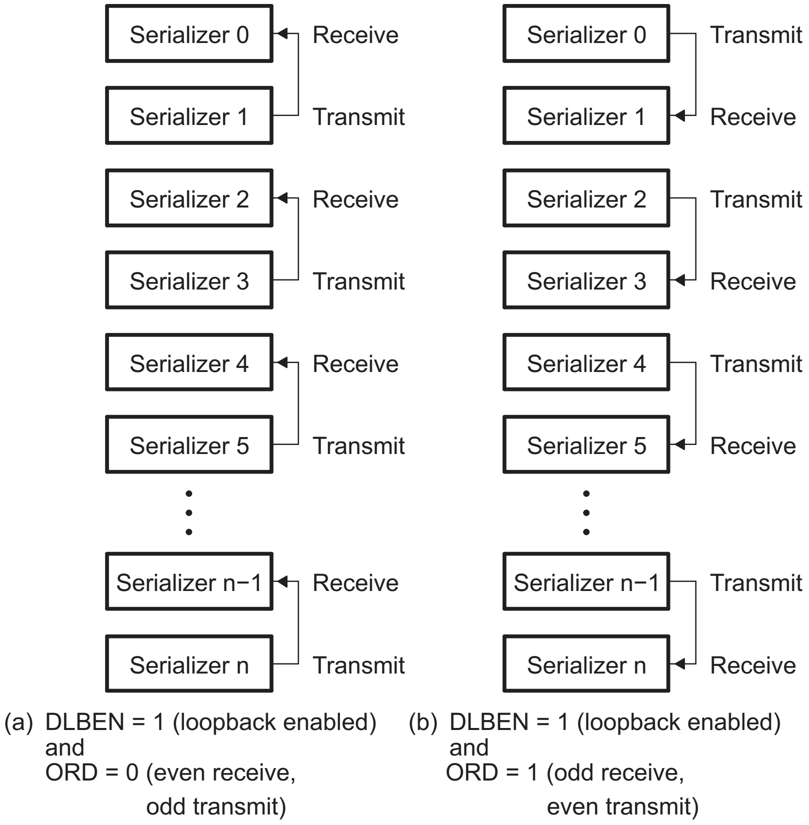
Figure 24-33 shows the basic logical connection of the serializers in loopback mode. Two types of loopback connections are possible, selected by the ORD bit in the digital loopback control register (DLBCTL) as follows:

- ORD = 0: Outputs of odd serializers are connected to inputs of even serializers. If this mode is selected, you should configure odd serializers to be transmitters and even serializers to be receivers.
- ORD = 1: Outputs of even serializers are connected to inputs of odd serializers. If this mode is selected, you should configure even serializers to be transmitters and odd serializers to be receivers.

Data can be externally visible at the I/O pin of the transmit serializer if the pin is configured as a McASP output pin by setting the corresponding PFUNC bit to 0 and PDIR bit to 1.

In loopback mode, the transmit clock and frame sync are used by both the transmit and receive sections of the McASP. The transmit and receive sections operate synchronously. This is achieved by setting the MODE bit of the DLBCTL register to 01b and the ASYNC bit of the ACLKXCTL register to 0.

Figure 24-33. Serializers in Loopback Mode



24.3.10.5.1 Loopback Mode Configurations

This is a summary of the settings required for digital loopback mode for TDM format:

- The DLBEN bit in DLBCTL must be set to 1 to enable loopback mode.
- The MODE bits in DLBCTL must be set to 01b for both the transmit and receive sections to use the transmit clock and frame sync generator.
- The ORD bit in DLBCTL must be programmed appropriately to select odd or even serializers to be transmitters or receivers. The corresponding serializers must be configured accordingly.
- The ASYNC bit in ACLKXCTL must be cleared to 0 to ensure synchronous transmit and receive operations.
- RMOD field in AFSRCTL and XMOD field in AFSXCTL must be set to 2h to 20h to indicate TDM mode. Loopback mode does not apply to DIT or burst mode.

24.3.11 Reset Considerations

The McASP has two reset sources: software reset and hardware reset.

24.3.11.1 Software Reset Considerations

The transmitter and receiver portions of the McASP may be put in reset through the global control register (GBLCTL). Note that a valid serial clock must be supplied to the desired portion of the McASP (transmit and/or receive) in order to assert the software reset bits in GBLCTL. see Section 24.3.12.2 for details on how to ensure reset has occurred.

The entire McASP module may also be reset through the Power and Sleep Controller (PSC). Note that from the McASP perspective, this reset appears as a hardware reset to the entire module.

24.3.11.2 Hardware Reset Considerations

When the McASP is reset due to device reset, the entire serial port (including the transmitter and receiver state machines, and other registers) is reset.

24.3.12 Setup and Initialization

This section discusses steps necessary to use the McASP module.

24.3.12.1 Considerations When Using a McASP

The following is a list of things to be considered for systems using a McASP:

24.3.12.1.1 Clocks

For each receive and transmit section:

- External or internal generated bit clock and high frequency clock?
- If internally generated, what is the bit clock speed and the high frequency clock speed?
- Clock polarity?
- External or internal generated frame sync?
- If internally generated, what is frame sync speed?
- Frame sync polarity?
- Frame sync width?
- Transmit and receive sync or asynchronous?

24.3.12.1.2 Data Pins

For each pin of each McASP:

- McASP or GPIO?
- Input or output?

24.3.12.1.3 Data Format

For each transmit and receive data:

- Internal numeric representation (integer, Q31 fraction)?
- I2S or DIT (transmit only)?
- Time slot delay (0, 1, or 2 bit)?
- Alignment (left or right)?
- Order (MSB first, LSB first)?
- Pad (if yes, pad with what value)?
- Slot size?
- Rotate?
- Mask?

24.3.12.1.4 Data Transfers

- Internal: DMA or CPU?
- External: TDM or burst?
- Bus: configuration bus (CFG) or data port (DAT)?

24.3.12.2 Transmit/Receive Section Initialization

You must follow the following steps to properly configure the McASP. If external clocks are used, they should be present prior to the following initialization steps.

1. Reset McASP to default values by setting GBLCTL = 0.
2. Configure all McASP registers except GBLCTL in the following order:
   a. Power Idle SYSCONFIG: PWRIDLESYSCONFIG.
   b. Receive registers: RMASK, RFMT, AFSRCTL, ACLKRCTL, AHCLKRCTL, RTDM, RINTCTL, RCLKCHK. If external clocks AHCLKR and/or ACLKR are used, they must be running already for proper synchronization of the GBLCTL register.
   c. Transmit registers: XMASK, XFMT, AFSXCTL, ACLKXCTL, AHCLKXCTL, XTDM, XINTCTL, XCLKCHK. If external clocks AHCLKX and/or ACLKX are used, they must be running already for proper synchronization of the GBLCTL register.
   d. Serializer registers: SRCTL[n].
   e. Global registers: Registers PFUNC, PDIR, DITCTL, DLBCTL, AMUTE. Note that PDIR should only be programmed after the clocks and frames are set up in the steps above. This is because the moment a clock pin is configured as an output in PDIR, the clock pin starts toggling at the rate defined in the corresponding clock control register. Therefore you must ensure that the clock control register is configured appropriately before you set the pin to be an output. A similar argument applies to the frame sync pins. Also note that the reset state for the transmit high-frequency clock divide register (HCLKXDIV) is divide-by-1, and the divide-by-1 clocks are not gated by the transmit high-frequency clock divider reset enable (XHCLKRST).
   f. DIT registers: For DIT mode operation, set up registers DITCSRA[n], DITCSRB[n], DITUDRA[n], and DITUDRB[n].
3. Start the respective high-frequency serial clocks AHCLKX and/or AHCLKR. This step is necessary even if external high-frequency serial clocks are used:
   a. Take the respective internal high-frequency serial clock divider(s) out of reset by setting the RHCLKRST bit for the receiver and/or the XHCLKRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be held at 0.
   b. Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.

4. Start the respective serial clocks ACLKX and/or ACLKR. This step can be skipped if external serial clocks are used and they are running:
   a. Take the respective internal serial clock divider(s) out of reset by setting the RCLKRST bit for the receiver and/or the XCLKRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
   b. Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
5. Setup data acquisition as required:
   a. If DMA is used to service the McASP, set up data acquisition as desired and start the DMA in this step, before the McASP is taken out of reset.
   b. If CPU interrupt is used to service the McASP, enable the transmit and/ or receive interrupt as required.
   c. If CPU polling is used to service the McASP, no action is required in this step.
6. Activate serializers.
   a. Before starting, clear the respective transmitter and receiver status registers by writing XSTAT = FFFFh and RSTAT = FFFFh.
   b. Take the respective serializers out of reset by setting the RSRCLR bit for the receiver and/or the XSRCLR bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
   c. Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
7. Verify that all transmit buffers are serviced. Skip this step if the transmitter is not used. Also, skip this step if time slot 0 is selected as inactive (special cases, see Figure 24-21, second waveform). As soon as the transmit serializer is taken out of reset, XDATA in the XSTAT register is set, indicating that XBUF is empty and ready to be serviced. The XDATA status causes an DMA event AXEVT to be generated, and can cause an interrupt AXINT to be generated if it is enabled in the XINTCTL register.
   a. If DMA is used to service the McASP, the DMA automatically services the McASP upon receiving AXEVT. Before proceeding in this step, you should verify that the XDATA bit in the XSTAT is cleared to 0, indicating that all transmit buffers are already serviced by the DMA.
   b. If CPU interrupt is used to service the McASP, interrupt service routine is entered upon the AXINT interrupt. The interrupt service routine should service the XBUF registers. Before proceeding in this step, you should verify that the XDATA bit in XSTAT is cleared to 0, indicating that all transmit buffers are already serviced by the CPU.
   c. If CPU polling is used to service the McASP, the XBUF registers should be written to in this step.
8. Release state machines from reset.
   I. Take the respective state machine(s) out of reset by setting the RSMRST bit for the receiver and/or the XSMRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
   II. Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
9. Release frame sync generators from reset. Note that it is necessary to release the internal frame sync generators from reset, even if an external frame sync is being used, because the frame sync error detection logic is built into the frame sync generator.
   a. Take the respective frame sync generator(s) out of reset by setting the RFRST bit for the receiver, and/or the XFRST bit for the transmitter in GBLCTL. All other bits in GBLCTL should be left at the previous state.
   b. Read back from GBLCTL to ensure the bit(s) to which you wrote are successfully latched in GBLCTL before you proceed.
10. Upon the first frame sync signal, McASP transfers begin. The McASP synchronizes to an edge on the frame sync pin, not the level on the frame sync pin. This makes it easy to release the state machine and frame sync generators from reset.
   a. For example, if you configure the McASP for a rising edge transmit frame sync, then you do not need to wait for a low level on the frame sync pin before releasing the McASP transmitter state

machine and frame sync generators from reset.

24.3.12.3 Separate Transmit and Receive Initialization

In many cases, it is desirable to separately initialize the McASP transmitter and receiver. For example, you may delay the initialization of the transmitter until the type of data coming in on the receiver is recognized. Or a change in the incoming data stream on the receiver may necessitate a reinitialization of the transmitter.

In this case, you may still follow the sequence outlined in Section 24.3.12.2, but use it for each section (transmit, receive) individually. The GBLCTL register is aliased to RGBLCTL and XGBLCTL to facilitate separate initialization of transmit and receive sections.

24.3.12.4 Importance of Reading Back GBLCTL

In Section 24.3.12.2, steps 3b, 4b, 6c, 8b, and 9b state that GBLCTL should be read back until the bits that were written are successfully latched. This is important, because the transmitter and receiver state machines run off of the respective bit clocks, which are typically about tens to hundreds of times slower than the processor's internal bus clock. Therefore, it takes many cycles between when the processor writes to GBLCTL (or RGBLCTL and XGBLCTL), and when the McASP actually recognizes the write operation. If you skip this step, then the McASP may never see the reset bits in the global control registers get asserted and de-asserted; resulting in an uninitialized McASP.

Therefore, the logic in McASP has been implemented such that once the processor writes GBLCTL, RGBLCTL, or XGBLCTL, the resulting write is not visible by reading back GBLCTL until the McASP has recognized the change. This typically requires two bit clocks plus two processor bus clocks to occur.

Also, if the bit clocks can be completely stopped, any software that polls GBLCTL should be implemented with a time-out. If GBLCTL does not have a time-out, and the bit clock stops, the changes written to GBLCTL will not be reflected until the bit clock restarts.

Finally, please note that while RGBLCTL and XGBLCTL allow separate changing of the receive and transmit halves of GBLCTL, they also immediately reflect the updated value (useful for debug purposes). Only GBLCTL can be used for the read back step.

24.3.12.5 Synchronous Transmit and Receive Operation (ASYNC = 0)

When ASYNC = 0 in ACLKXCTL, the transmit and receive sections operate synchronously from the transmit section clock and transmit frame sync signals (Figure 24-17). The receive section may have a different (but compatible in terms of slot size) data format.

When ASYNC = 0, the receive frame sync generator is internally disabled. If the AFSX pin is configured as an output, it serves as the frame sync signal for both transmit and receive. The AFSR pin should not be used because the transmit frame sync generator output, which is used by both the transmitter and the receiver when ASYNC = 0, is not propagated to the AFSR pin (Figure 24-19).

When ASYNC = 0, the transmit and receive sections must share some common settings, since they both use the same clock and frame sync signals:

- DITEN = 0 in DITCTL (TDM mode is enabled).
- The total number of bits per frame must be the same (that is, RSSZ × RMOD must equal XSSZ × XMOD).
- Both transmit and receive should either be specified as burst or TDM mode, but not mixed.
- The settings in ACLKRCTL are irrelevant.
- FSXM must match FSRM.
- FXWID must match FRWID.

For all other settings, the transmit and receive sections may be programmed independently.

24.3.12.6 Asynchronous Transmit and Receive Operation (ASYNC = 1)

When ASYNC = 1 in ACLKXCTL, the transmit and receive sections operate completely independently and have separate clock and frame sync signals (Figure 24-17, Figure 24-18, and Figure 24-19). The events generated by each section come asynchronously.

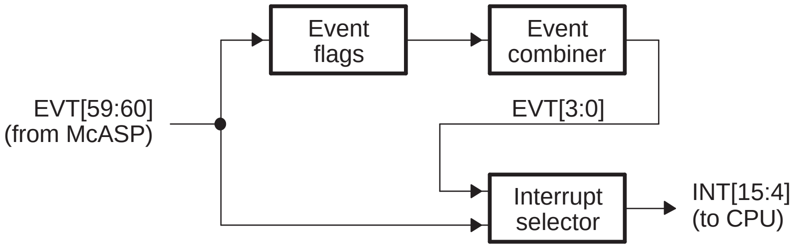
24.3.13 Interrupts

24.3.13.1 Interrupt Multiplexing

The processor includes an interrupt controller (INTC) to manage CPU interrupts. The INTC maps the device events to 12 CPU interrupts. The McASP generates 4 interrupts to the processor.

The event inputs can be routed to 12 maskable interrupts to the CPU (INT[15:4]). The INTC interrupt selector allows the McASP system events to be routed to any of the 12 CPU interrupt inputs. Furthermore, the INTC provides status flags and allows the combination of events, as shown in Figure 24-34. You must properly configure the INTC by enabling, masking, and routing the McASP system events to the desired CPU interrupts.

Figure 24-34. Interrupt Multiplexing



24.3.13.2 Transmit Data Ready Interrupt

The transmit data ready interrupt (XDATA) is generated if XDATA is 1 in the XSTAT register and XDATA is also enabled in XINTCTL. Section 24.3.10.1.1 provides details on when XDATA is set in the XSTAT register.

A transmit start of frame interrupt (XSTAFRM) is triggered by the recognition of transmit frame sync. A transmit last slot interrupt (XLAST) is a qualified version of the data ready interrupt (XDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended was next-to-last TDM slot, current slot is last slot).

24.3.13.3 Receive Data Ready Interrupt

The receive data ready interrupt (RDATA) is generated if RDATA is 1 in the RSTAT register and RDATA is also enabled in RINTCTL. Section 24.3.10.1.2 provides details on when RDATA is set in the RSTAT register.

A receiver start of frame interrupt (RSTAFRM) is triggered by the recognition of a receiver frame sync. A receiver last slot interrupt (RLAST) is a qualified version of the data ready interrupt (RDATA). It has the same behavior as the data ready interrupt, but is further qualified by having the data in the buffer come from the last TDM time slot (the slot that just ended was last TDM slot).

24.3.13.4 Error Interrupts

Upon detection, the following error conditions generate interrupt flags:

- In the receive status register (RSTAT):
  - Receiver overrun (ROVRN).
  - Unexpected receive frame sync (RSYNCERR).
  - Receive clock failure (RCKFAIL).
  - Receive DMA error (RDMAERR).

- In the transmit status register (XSTAT):
  - Transmit underrun (XUNDRN).
  - Unexpected transmit frame sync (XSYNCERR).
  - Transmit clock failure (XCKFAIL).
  - Transmit DMA error (XDMAERR).

Each interrupt source also has a corresponding enable bit in the receive interrupt control register (RINTCTL) and transmit interrupt control register (XINTCTL). If the enable bit is set in RINTCTL or XINTCTL, an interrupt is requested when the interrupt flag is set in RSTAT or XSTAT. If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

24.3.13.5 Audio Mute (AMUTE) Function

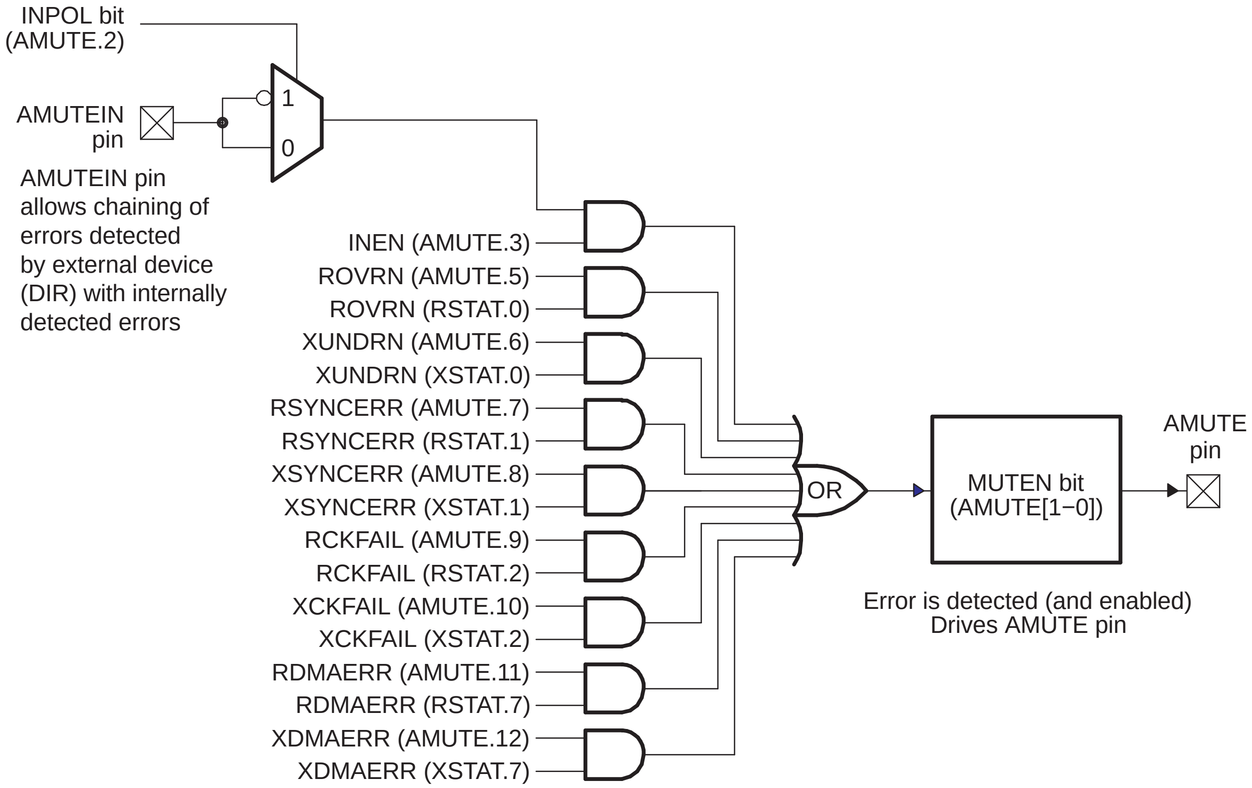
The McASP includes an automatic audio mute function (Figure 24-35) that asserts in hardware the AMUTE pin to a preprogrammed output state, as selected by the MUTEN bit in the audio mute control register (AMUTE). The AMUTE pin is asserted when one of the interrupt flags is set or an external device issues an error signal on the AMUTEIN input. Typically, the AMUTEIN input is shared with a device interrupt pin (for example EXT_INT4).

The AMUTEIN input allows the on-chip logic to consider a mute input from other devices in the system, so that all errors may be considered. The AMUTEIN input has a programmable polarity to allow it to adapt to different devices, as selected by the INPOL bit in AMUTE, and it must be enabled explicitly.

In addition to the external AMUTEIN input, the AMUTE pin output may be asserted when one of the error interrupt flags is set and its mute function is enabled in AMUTE.

When one or more of the errors is detected and enabled, the AMUTE pin is driven to an active state that is selected by MUTEN in AMUTE. The active polarity of the AMUTE pin is programmable by MUTEN (and the inactive polarity is the opposite of the active polarity). The AMUTE pin remains driven active until software clears all the error interrupt flags that are enabled to mute, and until the AMUTEIN is inactive.

Figure 24-35. Audio Mute (AMUTE) Block Diagram



24.3.13.6 Multiple Interrupts

This only applies to interrupts and not to DMA requests. The following terms are defined:

- **Active Interrupt Request:** a flag in RSTAT or XSTAT is set and the interrupt is enabled in RINTCTL or XINTCTL.
- **Outstanding Interrupt Request:** An interrupt request has been issued on one of the McASP transmit/receive interrupt ports, but that request has not yet been serviced.
- **Serviced:** The CPU writes to RSTAT or XSTAT to clear one or more of the active interrupt request flags.

The first interrupt request to become active for the transmitter with the interrupt flag set in XSTAT and the interrupt enabled in XINTCTL generates a request on the McASP transmit interrupt port AXINT.

If more than one interrupt request becomes active in the same cycle, a single interrupt request is generated on the McASP transmit interrupt port. Subsequent interrupt requests that become active while the first interrupt request is outstanding do not immediately generate a new request pulse on the McASP transmit interrupt port.

The transmit interrupt is serviced with the CPU writing to XSTAT. If any interrupt requests are active after the write, a new request is generated on the McASP transmit interrupt port.

The receiver operates in a similar way, but using RSTAT, RINTCTL, and the McASP receive interrupt port ARINT.

One outstanding interrupt request is allowed on each port, so a transmit and a receive interrupt request may both be outstanding at the same time.

24.3.14 EDMA Event Support

24.3.14.1 EDMA Events

There are 6 EDMA events.

24.3.14.2 Using the DMA for McASP Servicing

The most typical scenario is to use the DMA to service the McASP through the data port, although the DMA can also service the McASP through the configuration bus. Two possibilities exist for using the DMA events to service the McASP:

1. Use **AXEVT/AREVT**: Triggered upon each XDATA/RDATA transition from 0 to 1.
2. Use **AXEVTO/AREVTO** and **AXEVTE/AREVTE**: Alternating AXEVT/AREVT events for odd/even slots. Upon AXEVT/AREVT, AXEVTO/AREVTO is triggered if the event is for an odd channel, and AXEVTE/AREVTE is triggered if the event is for an even channel.

NOTE: Check the device-specific data manual to see if AXEVTO/AREVTO and AXEVTE/AREVTE are supported. These are optional.

Figure 24-36 and Figure 24-37 show an example audio system with six audio channels (LF, RF, LS, RS, C, and LFE) transmitted from three AXRn pins on the McASP. Figure 24-36 and Figure 24-37 show when events AXEVT, AXEVTO, and AXEVTE are triggered. Figure 24-36 and Figure 24-37 also apply for the receive audio channels and show when events AREVT, AREVTO, and AREVTE are triggered.

You can either use the DMA to service the McASP upon events AXEVT and AREVT (Figure 24-36) or upon events AXEVTO, AREVTO, AXEVTE, and AREVTE (Figure 24-37).

Figure 24-36. DMA Events in an Audio Example–Two Events (Scenario 1)

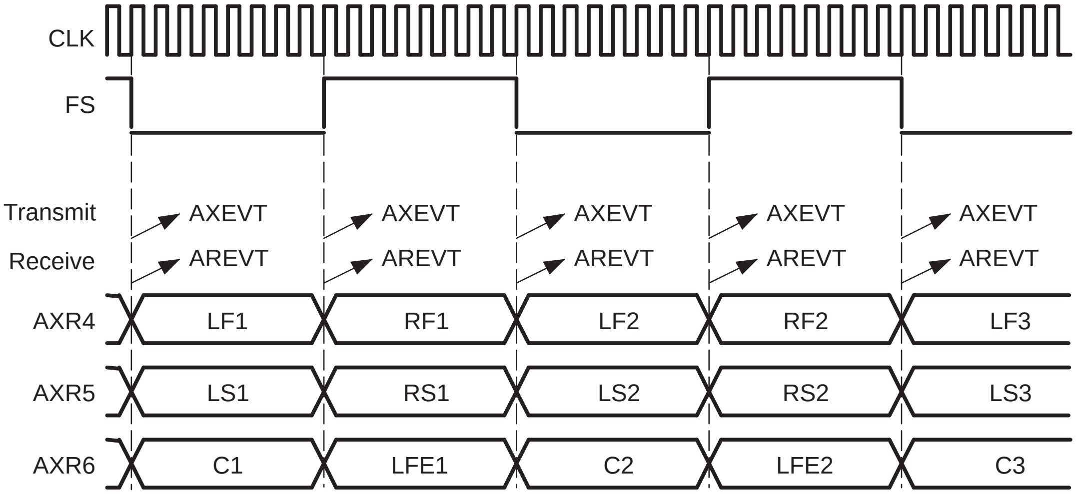


Figure 24-37. DMA Events in an Audio Example–Four Events (Scenario 2)

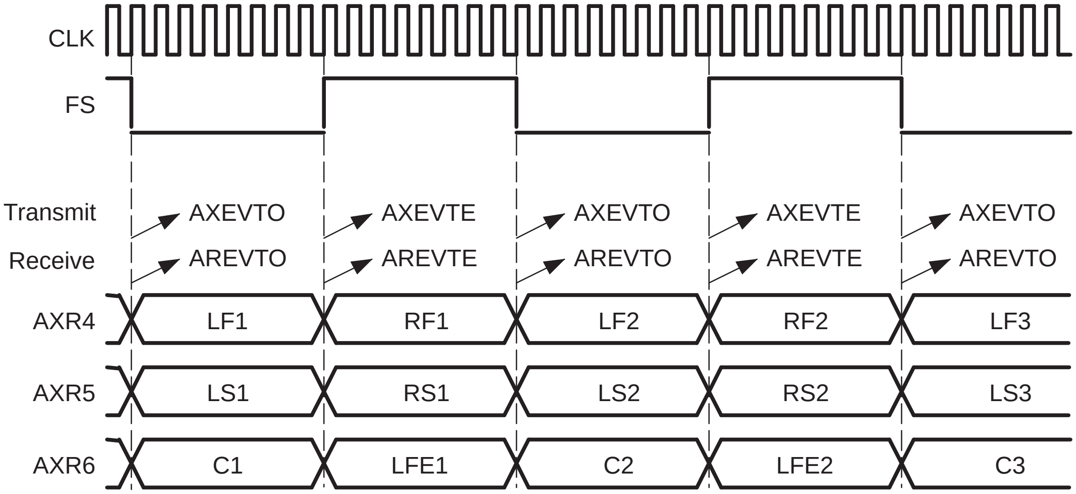


In scenario 1 (Figure 24-36), a DMA event AXEVT/AREVT is triggered on each time slot. In the example, AXEVT is triggered for each of the transmit audio channel time slot (Time slot for channels LF, LS, and C; and time slot for channels RF, RS, LFE). Similarly, AREVT is triggered for each of the receive audio channel time slot. Scenario 1 allows for the use of a single DMA to transmit all audio channels, and a single DMA to receive all audio channels.

In scenario 2 (Figure 24-37), two alternating DMA events are triggered for each time slot. In the example, AXEVTE (even) is triggered for the time slot for the even audio channels (LF, LS, C) and AXEVTO (odd) is triggered for the time slot for the odd audio channels (RF, RS, LFE). AXEVTO and AXEVTE alternate in time. The same is true in the receive direction with the use of AREVTO and AREVTE. This scenario allows for the use of two DMA channels (odd and even) to transmit all audio channels, and two DMA channels to receive all audio channels.

Here are some guidelines on using the different DMA events:

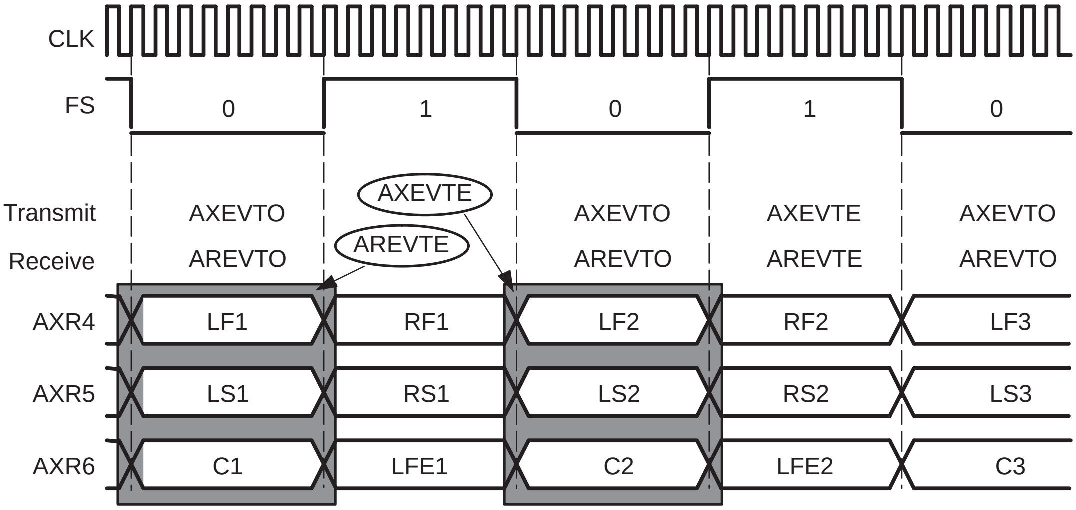
- Either use AXEVT, or the combination of AXEVTO and AXEVTE, to service the McASP. Never use all three at the same time. Similarly for receive, either use AREVT, or the combination of AREVTO and AREVTE.
- The McASP generates transmit DMA events independently from receive DMA events; therefore, separate schemes can be used for transmit and receive DMA. For example, scenario 1 could be used for the transmit data (AXEVT) and scenario 2 could be used for the receive data (AREVTO, AREVTE), and conversely.

Note the difference between DMA event generation and the CPU interrupt generation. DMA events are generated automatically upon data ready; whereas CPU interrupt generation needs to be enabled in the XINTCTL/RINTCTL register.

In Figure 24-37, scenario 2, each transmit DMA request is for data in the next time slot, while each receive DMA request is for data in the previous time slot. For example, Figure 24-38 shows a circled AXEVTE event for an even time slot transmit DMA request. The transmitter always requests a DMA transfer for data it will need to transmit during the next time slot. So, in this example, the circled event AXEVTE is a request for data for samples LF2, LS2, and C2.

On the other hand, the circled AREVTE event is an even time slot receive DMA request. The receiver always requests a DMA transfer for data it received during the previous time slot. In this example, the circled event AREVTE is a request for samples LF1, LS1, and C1.

Figure 24-38. DMA Events in an Audio Example



24.3.15 Power Management

The McASP can be placed in reduced power modes to conserve power during periods of low activity.

24.3.16 Emulation Considerations

NOTE: The receive buffer registers (RBUF*n*) and transmit buffer registers (XBUF*n*) should not be accessed by the emulator when the McASP is running. Such an access will cause the RRDY/XRDY bit in the serializer control register *n* (SRCTL*n*) to be updated.

The McASP does not support the emulation suspend.

24.4 McASP Registers

24.4.1 MCASP Registers

Table 24-11 lists the memory-mapped registers for the MCASP. All register offset addresses not listed in Table 24-11 should be considered as reserved locations and the register contents should not be modified.

Table 24-11. MCASP REGISTERS

Offset	Acronym	Register Name	Section

24.4.1.1 MCASP_REV Register (offset = 0h) [reset = 44300A02h]

MCASP_REV is shown in Figure 24-39 and described in Table 24-12.

The revision identification register (REV) contains identification data for the peripheral.

Figure 24-39. MCASP_REV Register

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>

1-0	IDLEMODE	R/W	2h	Power management Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0h = Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, i.e. regardless of the IP module's internal requirements. Backup mode, for debug only. 1h = No-idle mode: local target never enters idle state. Backup mode, for debug only. 2h = Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wakeup events. 3h = Reserved.

24.4.1.3 MCASP_PFUNC Register (offset = 10h) [reset = 0h]

MCASP_PFUNC is shown in Figure 24-41 and described in Table 24-14.

The pin function register (PFUNC) specifies the function of AXRn, ACLKX, AHCLKX, AFSX, ACLKR, AHCLKR, and AFSR pins as either a McASP pin or a general-purpose input/output (GPIO) pin. CAUTION: Writing a value other than 0 to reserved bits in this register may cause improper device operation.

24.4.1.4 MCASP_PDIR Register (offset = 14h) [reset = 0h]

MCASP_PDIR is shown in Figure 24-42 and described in Table 24-15.

The pin direction register (PDIR) specifies the direction of AXRn, ACLKX, AHCLKX, AFSX, ACLKR, AHCLKR, and AFSR pins as either an input or an output pin. Regardless of the pin function register (PFUNC) setting, each PDIR bit must be set to 1 for the specified pin to be enabled as an output and each PDIR bit must be cleared to 0 for the specified pin to be an input. For example, if the McASP is configured to use an internally-generated bit clock and the clock is to be driven out to the system, the PFUNC bit must be cleared to 0 (McASP function) and the PDIR bit must be set to 1 (an output). When AXRn is configured to transmit, the PFUNC bit must be cleared to 0 (McASP function) and the PDIR bit must be set to 1 (an output). Similarly, when AXRn is configured to receive, the PFUNC bit must be cleared to 0 (McASP function) and the PDIR bit must be cleared to 0 (an input). CAUTION: Writing a value other than 0 to reserved bits in this register may cause improper device operation.

24.4.1.5 MCASP_PDOUT Register (offset = 18h) [reset = 0h]

MCASP_PDOUT is shown in Figure 24-43 and described in Table 24-16.

The pin data output register (PDOUT) holds a value for data out at all times, and may be read back at all times. The value held by PDOUT is not affected by writing to PDIR and PFUNC. However, the data value in PDOUT is driven out onto the McASP pin only if the corresponding bit in PFUNC is set to 1 (GPIO function) and the corresponding bit in PDIR is set to 1 (output). When reading data, returns the corresponding bit value in PDOUT[n], does not return input from I/O pin; when writing data, writes to the corresponding PDOUT[n] bit. PDOUT has these aliases or alternate addresses: PDSET When written to at this address, writing a 1 to a bit in PDSET sets the corresponding bit in PDOUT to 1; writing a 0 has no effect and keeps the bits in PDOUT unchanged. PDCLR When written to at this address, writing a 1 to a bit in PDCLR clears the corresponding bit in PDOUT to 0; writing a 0 has no effect and keeps the bits in PDOUT unchanged. There is only one set of data out bits, PDOUT[31-0]. The other registers, PDSET and PDCLR, are just different addresses for the same control bits, with different behaviors during writes. CAUTION: Writing a value other than 0 to reserved bits in this register may cause improper device operation.

24.4.1.6 MCASP_PDIN Register (offset = 1Ch) [reset = 0h]

MCASP_PDIN is shown in Figure 24-44 and described in Table 24-17.

The pin data input register (PDIN) holds the I/O pin state of each of the McASP pins. PDIN allows the actual value of the pin to be read, regardless of the state of PFUNC and PDIR. The value after reset for registers 1 through 15 and 24 through 31 depends on how the pins are being driven. CAUTION: Writing a value other than 0 to reserved bits in this register may cause improper device operation.

24.4.1.7 MCASP_PDCLR Register (offset = 20h) [reset = 0h]

MCASP_PDCLR is shown in Figure 24-45 and described in Table 24-18.

The pin data clear register (PDCLR) is an alias of the pin data output register (PDOUT) for writes only. Writing a 1 to the PDCLR bit clears the corresponding bit in PDOUT and, if PFUNC = 1 (GPIO function) and PDIR = 1 (output), drives a logic low on the pin. PDCLR is useful for a multitasking system because it allows you to clear to a logic low only the desired pin(s) within a system without affecting other I/O pins controlled by the same McASP. CAUTION: Writing a value other than 0 to reserved bits in this register may cause improper device operation.

24.4.1.8 MCASP_GBLCTL Register (offset = 44h) [reset = 0h]

MCASP_GBLCTL is shown in Figure 24-46 and described in Table 24-19.

The global control register (GBLCTL) provides initialization of the transmit and receive sections. The bit fields in GBLCTL are synchronized and latched by the corresponding clocks (ACLKX for bits 12-8 and ACLKR for bits 4-0). Before GBLCTL is programmed, you must ensure that serial clocks are running. If the corresponding external serial clocks, ACLKX and ACLKR, are not yet running, you should select the internal serial clock source in AHCLKXCTL, AHCLKRCTL, ACLKXCTL, and ACLKRCTL before GBLCTL is programmed. Also, after programming any bits in GBLCTL you should not proceed until you have read back from GBLCTL and verified that the bits are latched in GBLCTL.

Table 24-19. MCASP_GBLCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	
12	XFRST	R/W	0h	Transmit frame sync generator reset enable bit. 0h = Transmit frame sync generator is reset. 1h = Transmit frame sync generator is active. When released from reset, the transmit frame sync generator begins counting serial clocks and generating frame sync as programmed.
11	XSMRST	R/W	0h	Transmit state machine reset enable bit. 0h = Transmit state machine is held in reset. AXRn pin state: If PFUNC[n] = 0 and PDIR[n] = 1; then the serializer drives the AXRn pin to the state specified for inactive time slot (as determined by DISMOD bits in SRCTL). 1h = Transmit state machine is released from reset. When released from reset, the transmit state machine immediately transfers data from XRBUF[n] to XRSR[n]. The transmit state machine sets the underrun flag (XUNDRN) in XSTAT, if XRBUF[n] have not been preloaded with data before reset is released. The transmit state machine also immediately begins detecting frame sync and is ready to transmit. Transmit TDM time slot begins at slot 0 after reset is released.
10	XSRCLR	R/W	0h	Transmit serializer clear enable bit. By clearing then setting this bit, the transmit buffer is flushed to an empty state (XDATA = 1). If XSMRST = 1, XSRCLR = 1, XDATA = 1, and XBUF is not loaded with new data before the start of the next active time slot, an underrun will occur. 0h = Transmit serializers are cleared. 1h = Transmit serializers are active. When the transmit serializers are first taken out of reset (XSRCLR changes from 0 to 1), the transmit data ready bit (XDATA) in XSTAT is set to indicate XBUF is ready to be written.

Table 24-19. MCASP_GBLCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	XHCLKRST	R/W	0h	Transmit high-frequency clock divider reset enable bit. 0h = Transmit high-frequency clock divider is held in reset and passes through its input as divide-by-1. 1h = Transmit high-frequency clock divider is running.
8	XCLKRST	R/W	0h	Transmit clock divider reset enable bit. 0h = Transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 1h = Transmit clock divider is running.
7-5	RESERVED	R	0h	
4	RFRST	R/W	0h	Receive frame sync generator reset enable bit. 0h = Receive frame sync generator is reset. 1h = Receive frame sync generator is active. When released from reset, the receive frame sync generator begins counting serial clocks and generating frame sync as programmed.
3	RSMRST	R/W	0h	Receive state machine reset enable bit. 0h = Receive state machine is held in reset. 1h = Receive state machine is released from reset. When released from reset, the receive state machine immediately begins detecting frame sync and is ready to receive. Receive TDM time slot begins at slot 0 after reset is released.
2	RSRCLR	R/W	0h	Receive serializer clear enable bit. By clearing then setting this bit, the receive buffer is flushed. 0h = Receive serializers are cleared. 1h = Receive serializers are active.
1	RHCLKRST	R/W	0h	Receive high-frequency clock divider reset enable bit. 0h = Receive high-frequency clock divider is held in reset and passes through its input as divide-by-1. 1h = Receive high-frequency clock divider is running.
0	RCLKRST	R/W	0h	Receive high-frequency clock divider reset enable bit. 0h = Receive clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 1h = Receive clock divider is running.

24.4.1.9 MCASP_AMUTE Register (offset = 48h) [reset = 0h]

MCASP_AMUTE is shown in Figure 24-47 and described in Table 24-20.

The audio mute control register (AMUTE) controls the McASP audio mute (AMUTE) output pin. The value after reset for register 4 depends on how the pins are being driven.

Table 24-23. MCASP_RGBLCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-13	RESERVED	R	0h	
12	XFRST	R	0h	Transmit frame sync generator reset enable bit. A read of this bit returns the XFRST bit value of GBLCTL. Writes have no effect.
11	XSMRST	R	0h	Transmit state machine reset enable bit. A read of this bit returns the XSMRST bit value of GBLCTL. Writes have no effect.
10	XSRCLR	R	0h	Transmit serializer clear enable bit. A read of this bit returns the XSRCLR bit value of GBLCTL. Writes have no effect.
9	XHCLKRST	R	0h	Transmit high-frequency clock divider reset enable bit. A read of this bit returns the XHCLKRST bit value of GBLCTL. Writes have no effect.
8	XCLKRST	R	0h	Transmit clock divider reset enable bit. A read of this bit returns the XCLKRST bit value of GBLCTL. Writes have no effect.
7-5	RESERVED	R	0h	
4	RFRST	R/W	0h	Receive frame sync generator reset enable bit. A write to this bit affects the RFRST bit of GBLCTL. 0h = Receive frame sync generator is reset. 1h = Receive frame sync generator is active.
3	RSMRST	R/W	0h	Receive state machine reset enable bit. A write to this bit affects the RSMRST bit of GBLCTL. 0h = Receive state machine is held in reset. 1h = Receive state machine is released from reset.
2	RSRCLR	R/W	0h	Receive serializer clear enable bit. A write to this bit affects the RSRCLR bit of GBLCTL. 0h = Receive serializers are cleared. 1h = Receive serializers are active.

Table 24-23. MCASP_RGBLCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	RHCLKRST	R/W	0h	Receive high-frequency clock divider reset enable bit. A write to this bit affects the RHCLKRST bit of GBLCTL. 0h = Receive high-frequency clock divider is held in reset and passes through its input as divide-by-1. 1h = Receive high-frequency clock divider is running.
0	RCLKRST	R/W	0h	Receive clock divider reset enable bit. A write to this bit affects the RCLKRST bit of GBLCTL. 0h = Receive clock divider is held in reset. 1h = Receive clock divider is running.

24.4.1.13 MCASP_RMASK Register (offset = 64h) [reset = 0h]

MCASP_RMASK is shown in Figure 24-51 and described in Table 24-24.

The receive format unit bit mask register (RMASK) determines which bits of the received data are masked off and padded with a known value before being read by the CPU or DMA.

Figure 24-51. MCASP_RMASK Register

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>

31-0	RTDMS	R/W	0h	Receiver mode during TDM time slot n. 0h = Receive TDM time slot n is inactive. The receive serializer does not shift in data during this slot. 1h = Receive TDM time slot n is active. The receive serializer shifts in data during this slot.

24.4.1.19 MCASP_RINTCTL Register (offset = 7Ch) [reset = 0h]

MCASP_RINTCTL is shown in Figure 24-57 and described in Table 24-30.

The receiver interrupt control register (RINTCTL) controls generation of the McASP receive interrupt (RINT). When the register bit(s) is set to 1, the occurrence of the enabled McASP condition(s) generates RINT. See the RSTAT register for a description of the interrupt conditions.

24.4.1.20 MCASP_RSTAT Register (offset = 80h) [reset = 0h]

MCASP_RSTAT is shown in Figure 24-58 and described in Table 24-31.

The receiver status register (RSTAT) provides the receiver status and receive TDM time slot number. If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes a new interrupt request to be generated.

Table 24-31. MCASP_RSTAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	
8	RERR	R/W	0h	RERR bit always returns a logic-OR of: ROVRN OR RSYNCERR OR RCKFAIL OR RDMAERR. Allows a single bit to be checked to determine if a receiver error interrupt has occurred. 0h = No errors have occurred. 1h = An error has occurred.
7	RDMAERR	R/W1C	0h	Receive DMA error flag. RDMAERR is set when the CPU or DMA reads more serializers through the data port in a given time slot than were programmed as receivers. Causes a receive interrupt (RINT), if this bit is set and RDMAERR in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0h = Receive DMA error did not occur. 1h = Receive DMA error did occur.
6	RSTAFRM	R/W1C	0h	Receive start of frame flag. Causes a receive interrupt (RINT), if this bit is set and RSTAFRM in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0h = No new receive frame sync (AFSR) is detected. 1h = A new receive frame sync (AFSR) is detected.
5	RDATA	R/W1C	0h	Receive data ready flag. Causes a receive interrupt (RINT), if this bit is set and RDATA in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0h = No new data in RBUF. 1h = Data is transferred from XRSR to RBUF and ready to be serviced by the CPU or DMA. When RDATA is set, it always causes a DMA event (AREVT).

Table 24-31. MCASP_RSTAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	RLAST	R/W1C	0h	Receive last slot flag. RLAST is set along with RDATA, if the current slot is the last slot in a frame. Causes a receive interrupt (RINT), if this bit is set and RLAST in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0h = Current slot is not the last slot in a frame. 1h = Current slot is the last slot in a frame. RDATA is also set.
3	RTDMSLOT	R	0h	Returns the LSB of RSLOT. Allows a single read of RSTAT to determine whether the current TDM time slot is even or odd. 0h = Current TDM time slot is odd. 1h = Current TDM time slot is even.
2	RCKFAIL	R/W1C	0h	Receive clock failure flag. RCKFAIL is set when the receive clock failure detection circuit reports an error. Causes a receive interrupt (RINT), if this bit is set and RCKFAIL in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0h = Receive clock failure did not occur. 1h = Receive clock failure did occur.
1	RSYNCERR	R/W1C	0h	Unexpected receive frame sync flag. RSYNCERR is set when a new receive frame sync (AFSR) occurs before it is expected. Causes a receive interrupt (RINT), if this bit is set and RSYNCERR in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0h = Unexpected receive frame sync did not occur. 1h = Unexpected receive frame sync did occur.
0	ROVRN	R/W1C	0h	Receiver overrun flag. ROVRN is set when the receive serializer is instructed to transfer data from XRSR to RBUF, but the former data in RBUF has not yet been read by the CPU or DMA. Causes a receive interrupt (RINT), if this bit is set and ROVRN in RINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 to this bit has no effect. 0h = Receiver overrun did not occur. 1h = Receiver overrun did occur.

24.4.1.21 MCASP_RSLOT Register (offset = 84h) [reset = 0h]

MCASP_RSLOT is shown in Figure 24-59 and described in Table 24-32.

The current receive TDM time slot register (RSLOT) indicates the current time slot for the receive data frame.

Figure 24-59. MCASP_RSLOT Register

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td colspan="23">RESERVED</td><td colspan="9">RSLOTCNT</td></tr>
<tr><td colspan="23">R-0h</td><td colspan="9">R-0h</td></tr>
</table>

Table 24-32. MCASP_RSLOT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	
8-0	RSLOTCNT	R	0h	0-17Fh = Current receive time slot count. Legal values: 0 to 383 (17Fh). TDM function is not supported for > 32 time slots. However, TDM time slot counter may count to 383 when used to receive a DIR block (transferred over TDM format).

24.4.1.22 MCASP_RCLKCHK Register (offset = 88h) [reset = 0h]

MCASP_RCLKCHK is shown in Figure 24-60 and described in Table 24-33.

The receive clock check control register (RCLKCHK) configures the receive clock failure detection circuit.

Figure 24-60. MCASP_RCLKCHK Register

31-24	23-16
RCNT	RMAX
R-0h	R/W-0h

15-8	7-4	3-0
RMIN	RESERVED	RPS
R/W-0h	R-0h	R/W-0h

Table 24-33. MCASP_RCLKCHK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RCNT	R	0h	Receive clock count value (from previous measurement). The clock circuit continually counts the number of system clocks for every 32 receive high-frequency master clock (AHCLKR) signals, and stores the count in RCNT until the next measurement is taken.
23-16	RMAX	R/W	0h	Receive clock maximum boundary. This 8 bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If the current counter value is greater than RMAX after counting 32 AHCLKR signals, RCKFAIL in RSTAT is set. The comparison is performed using unsigned arithmetic.
15-8	RMIN	R/W	0h	Receive clock minimum boundary. This 8 bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 receive high-frequency master clock (AHCLKR) signals have been received. If RCNT is less than RMIN after counting 32 AHCLKR signals, RCKFAIL in RSTAT is set. The comparison is performed using unsigned arithmetic.
7-4	RESERVED	R	0h	
3-0	RPS	R/W	0h	Receive clock check prescaler value. 0h = McASP system clock divided by 1. 1h = McASP system clock divided by 2. 2h = McASP system clock divided by 4. 3h = McASP system clock divided by 8. 4h = McASP system clock divided by 16. 5h = McASP system clock divided by 32. 6h = McASP system clock divided by 64. 7h = McASP system clock divided by 128. 8h = McASP system clock divided by 256. 9h = Reserved from 9h to Fh.

24.4.1.23 MCASP_REVTCTL Register (offset = 8Ch) [reset = 0h]

MCASP_REVTCTL is shown in Figure 24-61 and described in Table 24-34.

The receiver DMA event control register (REVTCTL) contains a disable bit for the receiver DMA event. Note for device-specific registers: Accessing REVTCTL not implemented on a specific device may cause improper operation.

24.4.1.24 MCASP_XGBLCTL Register (offset = A0h) [reset = 0h]

MCASP_XGBLCTL is shown in Figure 24-62 and described in Table 24-35.

Alias of the global control register (GBLCTL). Writing to the transmitter global control register (XGBLCTL) affects only the transmit bits of GBLCTL (bits 12-8). Reads from XGBLCTL return the value of GBLCTL. XGBLCTL allows the transmitter to be reset independently from the receiver. See the GBLCTL register for a detailed description of GBLCTL.

1	RHCLKRST	R	0h	Receive high-frequency clock divider reset enable bit. A read of this bit returns the RHCLKRST bit value of GBLCTL. Writes have no effect.
0	RCLKRST	R	0h	Receive clock divider reset enable bit. A read of this bit returns the RCLKRST bit value of GBLCTL. Writes have no effect.

24.4.1.25 MCASP_XMASK Register (offset = A4h) [reset = 0h]

MCASP_XMASK is shown in Figure 24-63 and described in Table 24-36.

The transmit format unit bit mask register (XMASK) determines which bits of the transmitted data are masked off and padded with a known value before being shifted out the McASP.

Figure 24-63. MCASP_XMASK Register

<table>

Table 24-37. MCASP_XFMT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-18	RESERVED	R	0h	
17-16	XDATDLY	R/W	0h	Transmit sync bit delay. 0h = 0-bit delay. The first transmit data bit, AXRn, occurs in same ACLKX cycle as the transmit frame sync (AFSX). 1h = 1-bit delay. The first transmit data bit, AXRn, occurs one ACLKX cycle after the transmit frame sync (AFSX). 2h = 2-bit delay. The first transmit data bit, AXRn, occurs two ACLKX cycles after the transmit frame sync (AFSX). 3h = Reserved.
15	XRVRS	R/W	0h	Transmit serial bitstream order. 0h = Bitstream is LSB first. No bit reversal is performed in transmit format bit reverse unit. 1h = Bitstream is MSB first. Bit reversal is performed in transmit format bit reverse unit.
14-13	XPAD	R/W	0h	Pad value for extra bits in slot not belonging to word defined by XMASK. This field only applies to bits when XMASK[n] = 0. 0h = Pad extra bits with 0. 1h = Pad extra bits with 1. 2h = Pad extra bits with one of the bits from the word as specified by XPBIT bits. 3h = Reserved.
12-8	XPBIT	R/W	0h	XPBIT value determines which bit (as written by the CPU or DMA to XBUF[n]) is used to pad the extra bits before shifting. This field only applies when XPAD = 2h. 0h = Pad with bit 0 value. 1h = Pad with bit 1 to bit 31 value from 1h to 1Fh.

Table 24-37. MCASP_XFMT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-4	XSSZ	R/W	0h	Transmit slot size. 0h = Reserved. 1h = Reserved. 2h = Reserved. 3h = Slot size is 8 bits. 4h = Reserved. 5h = Slot size is 12 bits. 6h = Reserved. 7h = Slot size is 16 bits. 8h = Reserved. 9h = Slot size is 20 bits. Ah = Reserved. 0xB = Slot size is 24 bits. Ch = Reserved. Dh = Slot size is 28 bits. Eh = Reserved. Fh = Slot size is 32 bits.
3	XBUSEL	R/W	0h	Selects whether writes to serializer buffer XRBUF[n] originate from the configuration bus (CFG) or the data (DAT) port. 0h = Writes to XRBUF[n] originate from the data port. Writes to XRBUF[n] from the configuration bus are ignored with no effect to the McASP. 1h = Writes to XRBUF[n] originate from the configuration bus. Writes to XRBUF[n] from the data port are ignored with no effect to the McASP.
2-0	XROT	R/W	0h	Right-rotation value for transmit rotate right format unit. 0h = Rotate right by 0 (no rotation). 1h = Rotate right by 4 bit positions. 2h = Rotate right by 8 bit positions. 3h = Rotate right by 12 bit positions. 4h = Rotate right by 16 bit positions. 5h = Rotate right by 20 bit positions. 6h = Rotate right by 24 bit positions. 7h = Rotate right by 28 bit positions.

24.4.1.27 MCASP_AFSXCTL Register (offset = ACh) [reset = 0h]

MCASP_AFSXCTL is shown in Figure 24-65 and described in Table 24-38.

The transmit frame sync control register (AFSXCTL) configures the transmit frame sync (AFSX).

24.4.1.30 MCASP_XTDM Register (offset = B8h) [reset = 0h]

MCASP_XTDM is shown in Figure 24-68 and described in Table 24-41.

The transmit TDM time slot register (XTDM) specifies in which TDM time slot the transmitter is active. TDM time slot counter range is extended to 384 slots (to support SPDIF blocks of 384 subframes). XTDM operates modulo 32, that is, XTDMS specifies the TDM activity for time slots 0, 32, 64, 96, 128, and so on.

31-0	XTDMS	R/W	0h	Transmitter mode during TDM time slot n. 0h = Transmit TDM time slot n is inactive. The transmit serializer does not shift out data during this slot. 1h = Transmit TDM time slot n is active. The transmit serializer shifts out data during this slot according to the serializer control register (SRCTL).

24.4.1.31 MCASP_XINTCTL Register (offset = BCh) [reset = 0h]

MCASP_XINTCTL is shown in Figure 24-69 and described in Table 24-42.

The transmitter interrupt control register (XINTCTL) controls generation of the McASP transmit interrupt (XINT). When the register bit(s) is set to 1, the occurrence of the enabled McASP condition(s) generates XINT. See the XSTAT register for a description of the interrupt conditions.

6	RESERVED	R	0h	
5	XDATA	R/W	0h	Transmit data ready interrupt enable bit. 0h = Interrupt is disabled. A transmit data ready interrupt does not generate a McASP transmit interrupt (XINT). 1h = Interrupt is enabled. A transmit data ready interrupt generates a McASP transmit interrupt (XINT).
4	XLAST	R/W	0h	Transmit last slot interrupt enable bit. 0h = Interrupt is disabled. A transmit last slot interrupt does not generate a McASP transmit interrupt (XINT). 1h = Interrupt is enabled. A transmit last slot interrupt generates a McASP transmit interrupt (XINT).
3	XDMAERR	R/W	0h	Transmit DMA error interrupt enable bit. 0h = Interrupt is disabled. A transmit DMA error interrupt does not generate a McASP transmit interrupt (XINT). 1h = Interrupt is enabled. A transmit DMA error interrupt generates a McASP transmit interrupt (XINT).
2	XCKFAIL	R/W	0h	Transmit clock failure interrupt enable bit. 0h = Interrupt is disabled. A transmit clock failure interrupt does not generate a McASP transmit interrupt (XINT). 1h = Interrupt is enabled. A transmit clock failure interrupt generates a McASP transmit interrupt (XINT).
1	XSYNCERR	R/W	0h	Unexpected transmit frame sync interrupt enable bit. 0h = Interrupt is disabled. An unexpected transmit frame sync interrupt does not generate a McASP transmit interrupt (XINT). 1h = Interrupt is enabled. An unexpected transmit frame sync interrupt generates a McASP transmit interrupt (XINT).

Table 24-42. MCASP_XINTCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	XUNDRN	R/W	0h	Transmitter underrun interrupt enable bit. 0h = Interrupt is disabled. A transmitter underrun interrupt does not generate a McASP transmit interrupt (XINT). 1h = Interrupt is enabled. A transmitter underrun interrupt generates a McASP transmit interrupt (XINT).

24.4.1.32 MCASP_XSTAT Register (offset = C0h) [reset = 0h]

MCASP_XSTAT is shown in Figure 24-70 and described in Table 24-43.

The transmitter status register (XSTAT) provides the transmitter status and transmit TDM time slot number. If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes a new interrupt request to be generated.

Table 24-43. MCASP_XSTAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	
8	XERR	R/W	0h	XERR bit always returns a logic-OR of: XUNDRN OR XSYNCERR OR XCKFAIL OR XDMAERR. Allows a single bit to be checked to determine if a transmitter error interrupt has occurred. 0h = No errors have occurred. 1h = An error has occurred.
7	XDMAERR	R/W1C	0h	Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more serializers through the data port in a given time slot than were programmed as transmitters. Causes a transmit interrupt (XINT), if this bit is set and XDMAERR in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0h = Transmit DMA error did not occur. 1h = Transmit DMA error did occur.
6	XSTAFRM	R/W1C	0h	Transmit start of frame flag. Causes a transmit interrupt (XINT), if this bit is set and XSTAFRM in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0h = No new transmit frame sync (AFSX) is detected. 1h = A new transmit frame sync (AFSX) is detected.
5	XDATA	R/W1C	0h	Transmit data ready flag. Causes a transmit interrupt (XINT), if this bit is set and XDATA in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0h = XBUF is written and is full. 1h = Data is copied from XBUF to XRSR. XBUF is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT).

Table 24-43. MCASP_XSTAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	XLAST	R/W1C	0h	Transmit last slot flag. XLAST is set along with XDATA, if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT), if this bit is set and XLAST in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0h = Current slot is not the last slot in a frame. 1h = Current slot is the last slot in a frame. XDATA is also set.
3	XTDMSLOT	R	0h	Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd. 0h = Current TDM time slot is odd. 1h = Current TDM time slot is even.
2	XCKFAIL	R/W1C	0h	Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error. Causes a transmit interrupt (XINT), if this bit is set and XCKFAIL in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0h = Transmit clock failure did not occur. 1h = Transmit clock failure did occur.
1	XSYNCERR	R/W1C	0h	Unexpected transmit frame sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT), if this bit is set and XSYNCERR in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0h = Unexpected transmit frame sync did not occur. 1h = Unexpected transmit frame sync did occur.
0	XUNDRN	R/W1C	0h	Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF to XRSR, but XBUF has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT), if this bit is set and XUNDRN in XINTCTL is set. This bit is cleared by writing a 1 to this bit. Writing a 0 has no effect. 0h = Transmitter underrun did not occur. 1h = Transmitter underrun did occur. For details on McASP action upon underrun conditions, see Buffer Underrun Error - Transmitter.

24.4.1.33 MCASP_XSLOT Register (offset = C4h) [reset = 0h]

MCASP_XSLOT is shown in Figure 24-71 and described in Table 24-44.

The current transmit TDM time slot register (XSLOT) indicates the current time slot for the transmit data frame.

Figure 24-71. MCASP_XSLOT Register

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>
<tr><td colspan="22">RESERVED</td><td colspan="10">XSLOTCNT</td></tr>
<tr><td colspan="22">R-0h</td><td colspan="10">R-0h</td></tr>
</table>

Table 24-44. MCASP_XSLOT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	RESERVED	R	0h	
9-0	XSLOTCNT	R	0h	Current transmit time slot count. Legal values: 0 to 383 (17Fh). During reset, this counter value is 383 so the next count value, which is used to encode the first DIT group of data, will be 0 and encodes the B preamble. TDM function is not supported for >32 time slots. However, TDM time slot counter may count to 383 when used to transmit a DIT block.

24.4.1.34 MCASP_XCLKCHK Register (offset = C8h) [reset = 0h]

MCASP_XCLKCHK is shown in Figure 24-72 and described in Table 24-45.

The transmit clock check control register (XCLKCHK) configures the transmit clock failure detection circuit.

Figure 24-72. MCASP_XCLKCHK Register

Table 24-45. MCASP_XCLKCHK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	XCNT	R	0h	Transmit clock count value (from previous measurement). The clock circuit continually counts the number of system clocks for every 32 transmit high-frequency master clock (AHCLKX) signals, and stores the count in XCNT until the next measurement is taken.
23-16	XMAX	R/W	0h	Transmit clock maximum boundary. This 8 bit unsigned value sets the maximum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (AHCLKX) signals have been received. If the current counter value is greater than XMAX after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.
15-8	XMIN	R/W	0h	Transmit clock minimum boundary. This 8 bit unsigned value sets the minimum allowed boundary for the clock check counter after 32 transmit high-frequency master clock (AHCLKX) signals have been received. If XCNT is less than XMIN after counting 32 AHCLKX signals, XCKFAIL in XSTAT is set. The comparison is performed using unsigned arithmetic.
7-4	RESERVED	R	0h	
3-0	XPS	R/W	0h	Transmit clock check prescaler value. Fh = Reserved from 9h to Fh. 0h = McASP system clock divided by 1. 1h = McASP system clock divided by 2. 2h = McASP system clock divided by 4. 3h = McASP system clock divided by 8. 4h = McASP system clock divided by 16. 5h = McASP system clock divided by 32. 6h = McASP system clock divided by 64. 7h = McASP system clock divided by 128. 8h = McASP system clock divided by 256. 9h = Reserved from 9h to Fh.

24.4.1.35 MCASP_XEVTCTL Register (offset = CCh) [reset = 0h]

MCASP_XEVTCTL is shown in Figure 24-73 and described in Table 24-46.

The transmitter DMA event control register (XEVTCTL) contains a disable bit for the transmit DMA event. Note for device-specific registers: Accessing XEVTCTL not implemented on a specific device may cause improper device operation.

24.4.1.36 MCASP_DITCSRA0 to MCASP_DITCSRA5 Register (offset = 100h to 114h) [reset = 0h]

MCASP_DITCSRA0 to MCASP_DITCSRA5 is shown in Figure 24-74 and described in Table 24-47.

The DIT left channel status registers (DITCSRA) provide the status of each left channel (even TDM time slot). Each of the six 32-bit registers can store 192 bits of channel status data for a complete block of transmission. The DIT reuses the same data for the next block. It is your responsibility to update the register file in time, if a different set of data need to be sent.

Figure 24-74. MCASP_DITCSRA0 to MCASP_DITCSRA5 Register

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	
5	RRDY	R	0h	Receive buffer ready bit. RRDY indicates the current receive buffer state. Always reads 0 when programmed as a transmitter or as inactive. If SRMOD bit is set to receive (2h), RRDY switches from 0 to 1 whenever data is transferred from XRSR to RBUF. 0h = Receive buffer (RBUF) is empty. 1h = Receive buffer (RBUF) contains data and needs to be read before the start of the next time slot or a receiver overrun occurs.
4	XRDY	R	0h	Transmit buffer ready bit. XRDY indicates the current transmit buffer state. Always reads 0 when programmed as a receiver or as inactive. If SRMOD bit is set to transmit (1h), XRDY switches from 0 to 1 when XSRCLR in GBLCTL is switched from 0 to 1 to indicate an empty transmitter. XRDY remains set until XSRCLR is forced to 0, data is written to the corresponding transmit buffer, or SRMOD bit is changed to receive (2h) or inactive (0). 0h = Transmit buffer (XBUF) contains data. 1h = Transmit buffer (XBUF) is empty and needs to be written before the start of the next time slot or a transmit underrun occurs.
3-2	DISMOD	R/W	0h	Serializer pin drive mode bit. Drive on pin when in inactive TDM slot of transmit mode or when serializer is inactive. This field only applies if the pin is configured as a McASP pin (PFUNC = 0). 0h = Drive on pin is 3-state. 1h = Reserved. 2h = Drive on pin is logic low. 3h = Drive on pin is logic high.

Controller Area Network (CAN)

This chapter describes the controller area network (CAN) for the device.

Topic **Page**

25.1 Introduction

25.1.1 DCAN Features

The general features of the DCAN controller are:

- Supports CAN protocol version 2.0 part A, B (ISO 11898-1)
- Bit rates up to 1 MBit/s
- Dual clock source
- 16, 32, 64 or 128 message objects (instantiated as 64 on this device)
- Individual identifier mask for each message object
- Programmable FIFO mode for message objects
- Programmable loop-back modes for self-test operation
- Suspend mode for debug support
- Software module reset
- Automatic bus on after Bus-Off state by a programmable 32-bit timer
- Message RAM parity check mechanism
- Direct access to Message RAM during test mode
- CAN Rx / Tx pins configurable as general purpose IO pins
- Two interrupt lines (plus additional parity-error interrupt line)
- RAM initialization
- DMA support

25.1.2 Unsupported DCAN Features

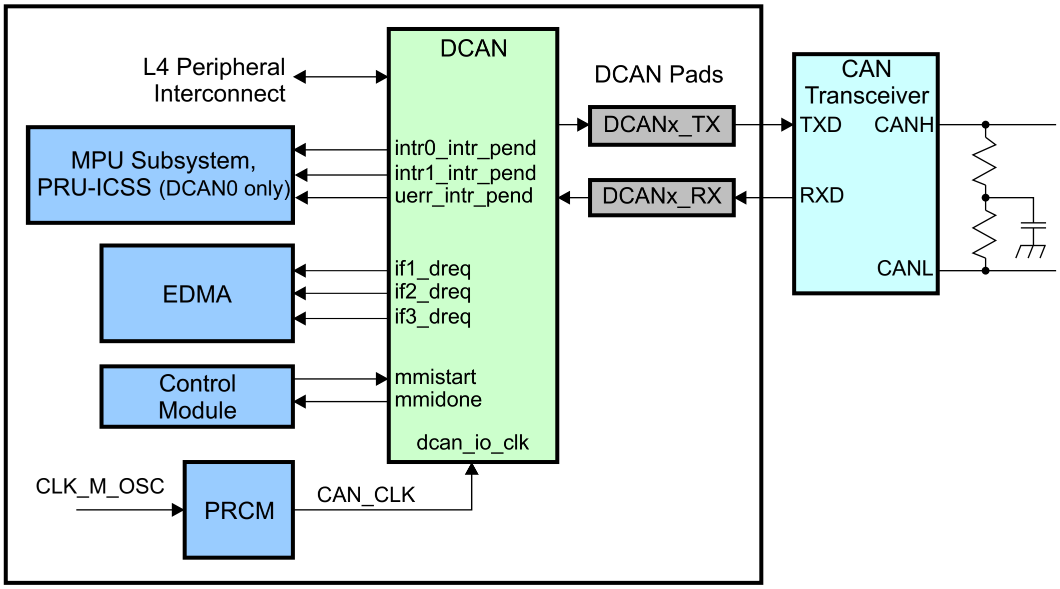
The DCAN module in this device does not support GPIO pin mode. All GPIO functionality is mapped through the GPIO modules and muxed at the pins. GPIO pin control signals from the DCAN modules are not connected.

25.2 Integration

The Controller Area Network is a serial communications protocol which efficiently supports distributed realtime control with a high level of security. The DCAN module supports bitrates up to 1 Mbit/s and is compliant to the CAN 2.0B protocol specification. The core IP within DCAN is provided by Bosch.

This device includes two instantiations of the DCAN controller: DCAN0 and DCAN1. Figure 25-1 shows the DCAN module integration.

Figure 25-1. DCAN Integration



25.2.1 DCAN Connectivity Attributes

The general connectivity attributes for the DCAN module are shown in Table 25-1.

Table 25-1. DCAN Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK (OCP) PD_PER_CAN_CLK (Func)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	3 Interrupts per instance Intr0 (DCANx_INT0) – Error, Status, Msg Object interrupt Intr1 (DCANx_INT1) – Msg Object interrupt Uerr (DCANx_PARITY) – Parity error interrupt All DCAN0 interrupts to MPU Subsystem and PRU-ICSS All DCAN1 interrupts to only MPU Subsystem
DMA Requests	3 DMA requests per instance to EDMA (CAN_IFxDMA)
Physical Address	L4 Peripheral slave port

25.2.2 DCAN Clock and Reset Management

The DCAN controllers have separate bus interface and functional clocks.

Table 25-2. DCAN Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
DCAN_ocp_clk Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk from PRCM
DCAN_io_clk Functional clock	26 MHz	CLK_M_OSC	pd_per_can_clk from PRCM

25.2.3 DCAN Pin List

The external signals for the DCAN module are shown in the following table.

Table 25-3. DCAN Pin List

Pin	Type	Description
DCAN*x*_TX	O	DCAN transmit line
DCAN*x*_RX	I	DCAN receive line

25.3 Functional Description

The DCAN module performs CAN protocol communication according to ISO 11898-1. The bit rate can be programmed to values up to 1 MBit/s. Additional transceiver hardware is required for the connection to the physical layer (CAN bus).

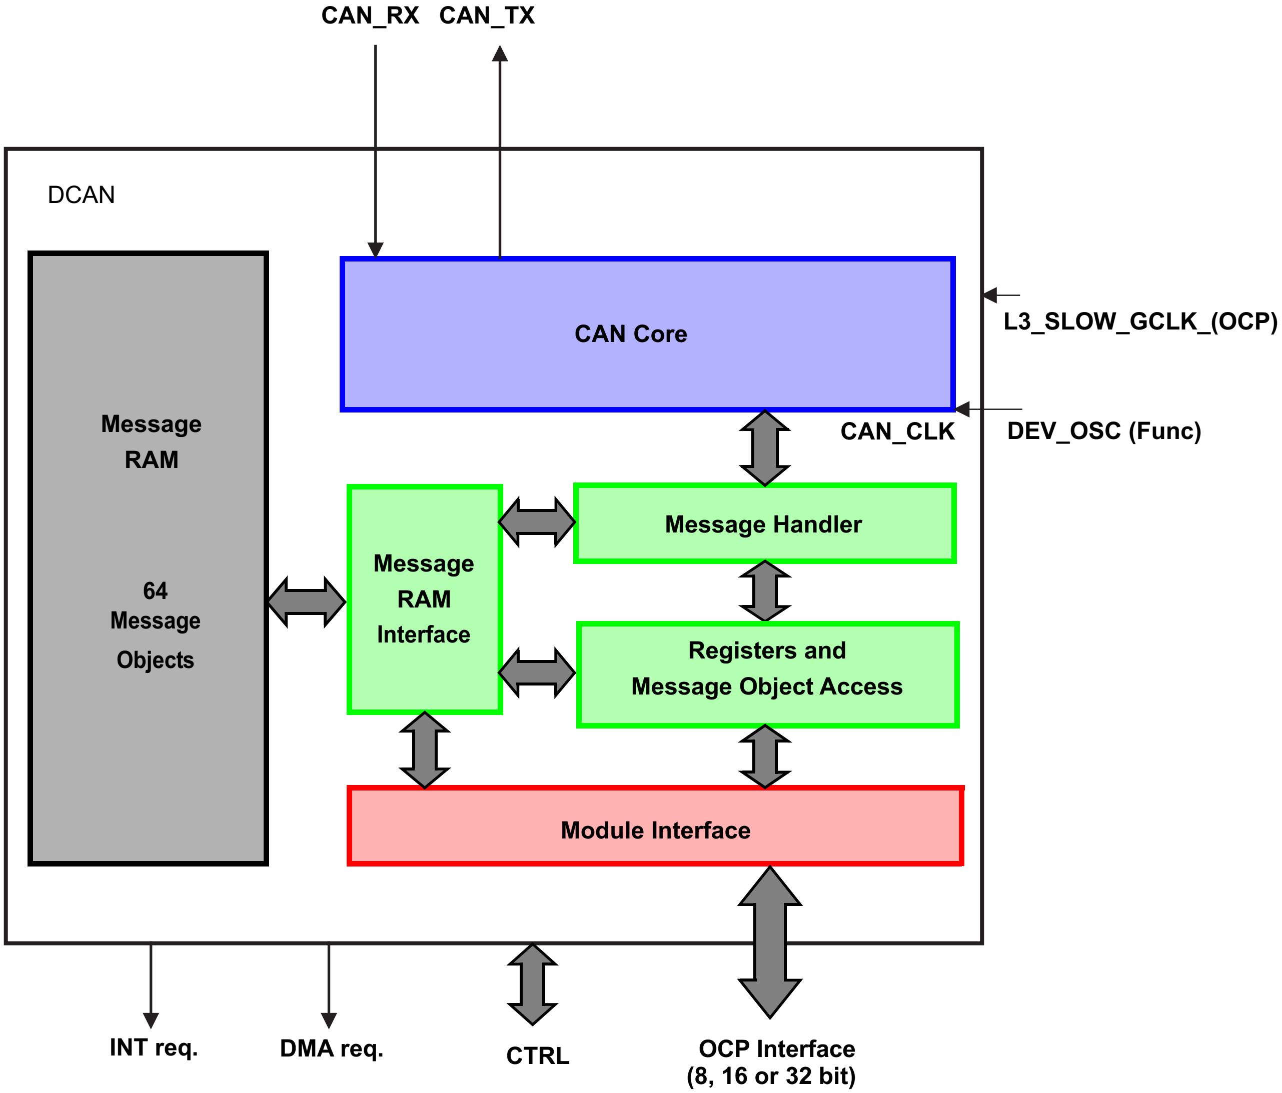
For communication on a CAN network, individual message objects can be configured. The message objects and identifier masks are stored in the message RAM.

All functions concerning the handling of messages are implemented in the message handler. Those functions are acceptance filtering, the transfer of messages between the CAN core and the message RAM, and the handling of transmission requests, as well as the generation of interrupts or DMA requests.

The register set of the DCAN module can be accessed directly by the CPU via the module interface. These registers are used to control and configure the CAN core and the message handler, and to access the message RAM.

Figure 25-2 shows the DCAN block diagram and its features are described below.

Figure 25-2. DCAN Block Diagram



25.3.1 CAN Core

The CAN core consists of the CAN protocol controller and the Rx/Tx shift register. It handles all ISO 11898-1 protocol functions.

25.3.2 Message Handler

The message handler is a state machine that controls the data transfer between the single-ported message RAM and the CAN core’s Rx/Tx shift register. It also handles acceptance filtering and the interrupt/DMA request generation as programmed in the control registers.

25.3.3 Message RAM

The DCAN0 and DCAN1 enables a storage of 64 CAN messages.

25.3.4 Message RAM Interface

Three interface register sets control the CPU read and write accesses to the message RAM. There are two interface registers sets for read and write access, IF1 and IF2, and one interface register set for read access only, IF3. Additional information can be found in Section 25.3.15.12.

The interface registers have the same word-length as the message RAM.

25.3.5 Registers and Message Object Access

Data consistency is ensured by indirect accesses to the message objects. During normal operation, all CPU and DMA accesses to the message RAM are done through interface registers. In a dedicated test mode, the message RAM is memory mapped and can be directly accessed by either CPU or DMA.

25.3.6 Module Interface

The DCAN module registers are accessed by the CPU or user software through a 32-bit peripheral bus interface.

25.3.7 Dual Clock Source

Two clock domains are provided to the DCAN module: the peripheral synchronous clock domain (L3_SLOW_GCLK) and the peripheral asynchronous clock source domain (CLK_M_OSC) for CAN_CLK.

25.3.8 CAN Operation

After hardware reset, the Init bit in the CAN control register (CTL) is set and all CAN protocol functions are disabled. The CAN module must be initialized before operating it. Figure 25-3 illustrates the basic initialization flow for the CAN module.

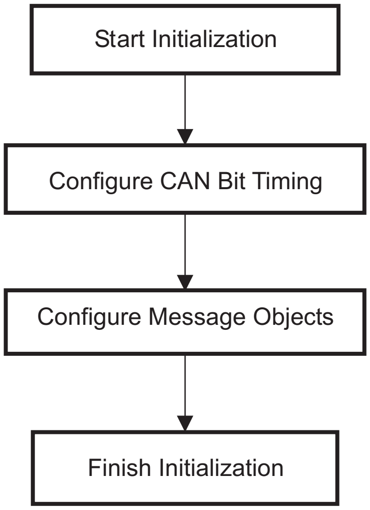
25.3.8.1 CAN Module Initialization

A general CAN module initialization would mean the following two critical steps:

- Configuration of the CAN bit timing
- Configuration of message objects

To initialize the CAN controller, the CPU has to set up the CAN bit timing and those message objects that have to be used for CAN communication. Message objects that are not needed, can be deactivated.

Figure 25-3. CAN Module General Initialization Flow



25.3.8.1.1 Configuration of CAN Bit Timing

The CAN module must be in initialization mode to configure the CAN bit timing.

For CAN bit timing software configuration flow, see Figure 25-4.

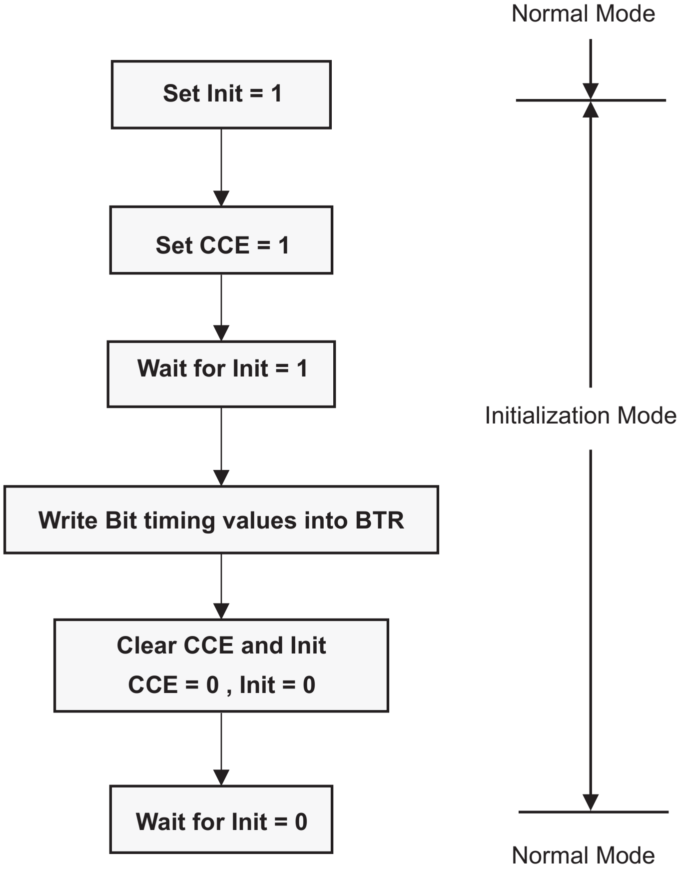
Step 1: Enter *initialization mode* by setting the Init (Initialization) bit in the CAN control register.

While the Init bit is set, the message transfer from and to the CAN bus is stopped, and the status of the CAN_TX output is recessive (high).

The CAN error counters are not updated. Setting the Init bit does not change any other configuration register.

Also, note that the CAN module is in initialization mode on hardware reset and during Bus-Off.

Figure 25-4. CAN Bit-Timing Configuration



Step 2: Set the Configure Change Enable (CCE) bit in the CAN control register.

The access to the Bit Timing register (BTR) for the configuration of the bit timing is enabled when both the Init and CCE bits in the CAN Control register are set.

Step 3: Wait for the Init bit to get set. This would make sure that the module has entered *Initialization mode*.

Step 4: Write the bit timing values into the bit timing register. See Section 25.3.16.2 for the BTR value calculation for a given bit timing.

Step 5: Clear the CCE and Init bit.

Step 6: Wait for the Init bit to clear. This would ensure that the module has come out of *initialization mode*.

Following these steps, the module comes to operation by synchronizing itself to the CAN bus, provided the BTR is configured as per the CAN bus baud rate, although the message objects have to be configured before carrying out any communication.

NOTE: The module will not come out of the *initialization mode* if any incorrect BTR values are written in step 4.

NOTE: The required message objects should be configured as transmit or receive objects before the start of data transfer as explained in Section 25.3.8.1.

25.3.8.1.2 Configuration of Message Objects

The message objects can be configured only through the interface registers; the CPU does not have direct access to the message object (message RAM) . Familiarize yourself with the interface register set (IFx) usage (see Section 25.3.17) and the message object structure (see Section 25.3.18) before configuring the message objects.

For more information regarding the procedure to configure the message objects, see Section 25.3.14. All the message objects should be configured to particular identifiers or set to not valid before the message transfer is started. It is possible to change the configuration of message objects during normal operation (that is between data transfers).

NOTE: The message objects initialization is independent of the bit-timing configuration.

25.3.8.1.3 DCAN RAM Hardware Initialization

The memory hardware initialization for the DCAN module is enabled in the device control register (DCAN_RAMINIT) which initializes the RAM with zeros and sets parity bits accordingly. Wait for the RAMINIT_DONE bit to be set to ensure successful RAM initialization. Ensure the clock to the DCAN module is enabled before starting this initialization.

For more details on RAM hardware initialization, see Chapter 7, *Control Module*.

25.3.8.2 CAN Message Transfer (Normal Operation)

Once the DCAN is initialized and the Init bit is reset to zero, the CAN core synchronizes itself to the CAN bus and is ready for message transfer as per the configured message objects.

The CPU may enable the interrupt lines (setting IE0 and IE1 to ‘1’) at the same time when it clears Init and CCE. The status interrupts EIE and SIE may be enabled simultaneously.

The CAN communication can be carried out in any of the following two modes: interrupt and polling.

The interrupt register points to those message objects with IntPnd = ‘1’. It is updated even if the interrupt lines to the CPU are disabled (IE0/IE1 are zero).

The CPU may poll all MessageObject’s NewDat and TxRqst bits in parallel from the NewData X registers and the Transmission Request X Registers (TXRQ X). Polling can be made easier if all transmit objects are grouped at the low numbers and all receive objects are grouped at the high numbers.

Received messages are stored into their appropriate message objects if they pass acceptance filtering.

The whole message (including all arbitration bits, DLC and up to eight data bytes) is stored into the message object. As a consequence (e.g., when the identifier mask is used), the arbitration bits which are masked to “don’t care” may change in the message object when a received message is stored.

The CPU may read or write each message at any time via the interface registers, as the message handler guarantees data consistency in case of concurrent accesses.

If a permanent message object (arbitration and control bits set up during configuration and leaving unchanged for multiple CAN transfers) exists for the message, it is possible to only update the data bytes.

If several transmit messages should be assigned to one message object, the whole message object has to be configured before the transmission of this message is requested.

The transmission of multiple message objects may be requested at the same time. They are subsequently transmitted, according to their internal priority.

Messages may be updated or set to not valid at any time, even if a requested transmission is still pending. However, the data bytes will be discarded if a message is updated before a pending transmission has started.

Depending on the configuration of the message object, a transmission may be automatically requested by the reception of a remote frame with a matching identifier.

25.3.8.2.1 Automatic Retransmission

According to the CAN Specification (ISO11898), the DCAN provides a mechanism to automatically retransmit frames which have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed.

By default, this automatic retransmission is enabled. It can be disabled by setting the disable automatic retransmission (DAR) bit in the CTL register. Further details to this mode are provided in Section 25.3.15.3.

25.3.8.2.2 Auto-Bus-On

By default, after the DCAN has entered Bus-Off state, the CPU can start a Bus-Off-Recovery sequence by resetting the Init bit. If this is not done, the module will stay in Bus-Off state.

The DCAN provides an automatic Auto-Bus-On feature which is enabled by bit ABO in the CTL register. If set, the DCAN module will automatically start the Bus-Off-Recovery sequence. The sequence can be delayed by a user-defined number of L3_SLOW_GCLK cycles which can be defined in the Auto-Bus-On Time register (ABOTR).

NOTE: If the DCAN goes to Bus-Off state due to a massive occurrence of CAN bus errors, it stops all bus activities and automatically sets the Init bit. Once the Init bit has been reset by the CPU or due to the Auto-Bus-On feature, the device will wait for 129 occurrences of bus Idle (equal to 129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus-Off recovery sequence, the error counters will be reset.

25.3.8.3 Test Modes

The DCAN module provides several test modes which are mainly intended for production tests or self test.

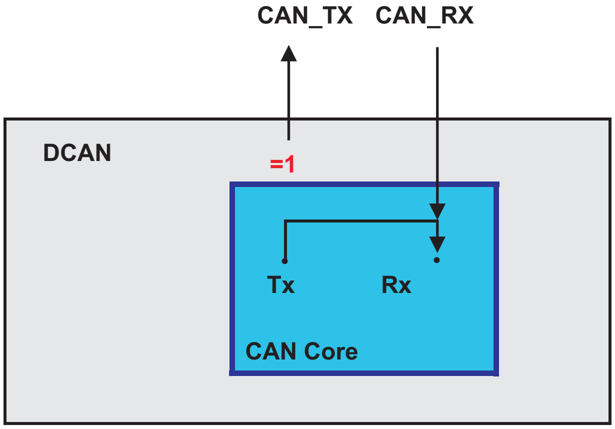
For all test modes, the Test bit in the CTL register needs to be set to one. This enables write access to the test register (TEST).

25.3.8.3.1 Silent Mode

The silent mode may be used to analyze the traffic on the CAN bus without affecting it by sending dominant bits (e.g., acknowledge bit, overload flag, active error flag). The DCAN is still able to receive valid data frames and valid remote frames, but it will not send any dominant bits. However, these are internally routed to the CAN core.

Figure 25-5 shows the connection of signals CAN_TX and CAN_RX to the CAN core in silent mode. Silent mode can be activated by setting the Silent bit in the TEST register to one. In ISO 11898-1, the silent mode is called the bus monitoring mode.

Figure 25-5. CAN Core in Silent Mode



25.3.8.3.2 Loopback Mode

The loopback mode is mainly intended for hardware self-test functions. In this mode, the CAN core uses internal feedback from Tx output to Rx input. Transmitted messages are treated as received messages, and can be stored into message objects if they pass acceptance filtering. The actual value of the CAN_RX input pin is disregarded by the CAN core. Transmitted messages can still be monitored at the CAN_TX pin.

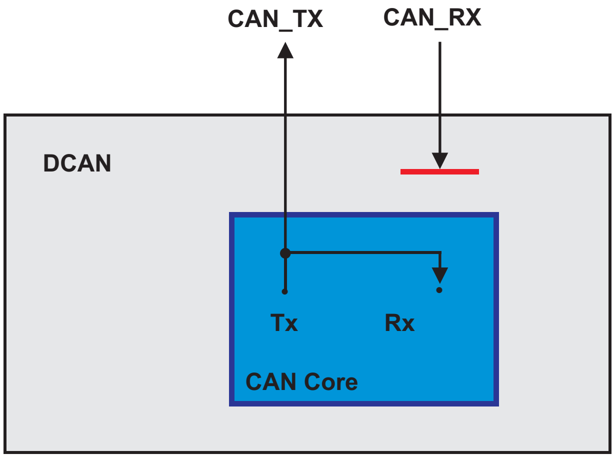
In order to be independent from external stimulation, the CAN core ignores acknowledge sampled in the acknowledge slot of a data/remote frame.

Figure 25-6 shows the connection of signals CAN_TX and CAN_RX to the CAN core in loopback mode.

Loopback mode can be activated by setting bit LBack in the TEST register to one.

NOTE: In loopback mode, the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core are disregarded. For including these into the testing, see Section 25.3.8.3.3.

Figure 25-6. CAN Core in Loopback Mode



25.3.8.3.3 External Loopback Mode

The external loopback mode is similar to the loopback mode; however, it includes the signal path from CAN core to Tx pin, the Tx pin itself, and the signal path from Tx pin back to CAN core. When external loopback mode is selected, the input of the CAN core is connected to the input buffer of the Tx pin.

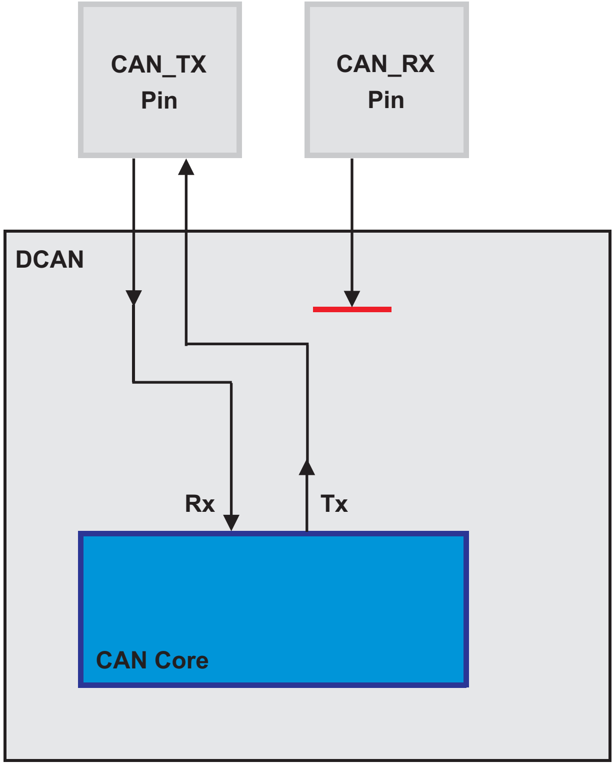
With this configuration, the Tx pin IO circuit can be tested.

External loopback mode can be activated by setting bit **EXL** in the TEST register to one.

Figure 25-7 shows the connection of signals CAN_TX and CAN_RX to the CAN core in external loopback mode.

NOTE: When loopback mode is active (LBack bit set), the ExL bit will be ignored.

Figure 25-7. CAN Core in External Loopback Mode

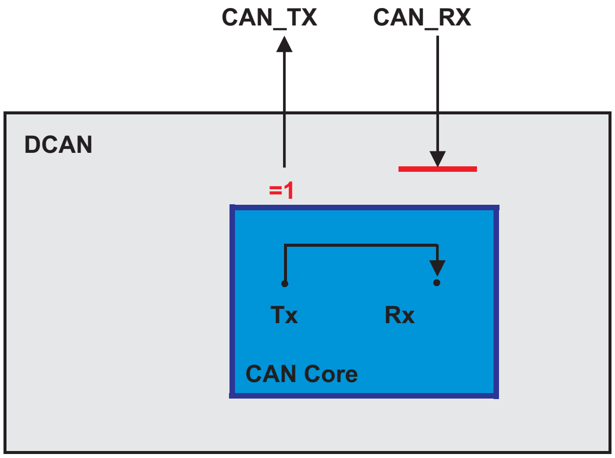


25.3.8.3.4 Loopback Mode Combined With Silent Mode

It is also possible to combine loopback mode and silent mode by setting bits LBack and Silent at the same time. This mode can be used for a “Hot Selftest,” that is, the DCAN hardware can be tested without affecting the CAN network. In this mode, the CAN_RX pin is disconnected from the CAN core and no dominant bits will be sent on the CAN_TX pin.

Figure 25-8 shows the connection of the signals CAN_TX and CAN_RX to the CAN core in case of the combination of loopback mode with silent mode.

Figure 25-8. CAN Core in Loop Back Combined With Silent Mode



25.3.8.3.5 Software Control of CAN_TX pin

Four output functions are available for the CAN transmit pin CAN_TX. In addition to its default function (serial data output), the CAN_TX pin can drive constant dominant or recessive values, or it can drive the CAN sample point signal to monitor the CAN core's bit timing.

Combined with the readable value of the CAN_RX pin, this function can be used to check the physical layer of the CAN bus.

The output mode of pin CAN_TX is selected by programming the TEST register bits Tx[1:0].

NOTE: The software control for the CAN_TX pin interferes with CAN protocol functions. For CAN message transfer or any of the test modes (loopback mode, external loopback mode or silent mode), the CAN_TX pin should operate in its default functionality.

25.3.9 Dual Clock Source

Two clock domains are provided to the DCAN module: the peripheral synchronous clock domain (L3_SLOW_GCLK) as the general module clock source, and the peripheral asynchronous clock source domain (CLK_M_OSC) provided to the CAN core (as clock source CAN_CLK) for generating the CAN bit timing.

Both clock domains can be derived from the same clock source (so that L3_SLOW_GCLK = CLK_M_OSC).

For more information on how to configure the relevant clock source registers in the system module, see Chapter 6, Power and Clock Management.

Between the two clock domains, a synchronization mechanism is implemented in the DCAN module in order to ensure correct data transfer.

NOTE: If the dual clock functionality is used, then L3_SLOW_GCLK must always be higher or equal to CAN_CLK (CLK_M_OSC) (derived from the asynchronous clock source), in order to achieve a stable functionality of the DCAN. Here also the frequency shift of the modulated L3_SLOW_GCLK has to be considered:

$f_{0,\ \mathrm{L3\_SLOW\_GCLK}}(\mathrm{OCP}) \pm \Delta f_{\mathrm{FM},\ \mathrm{L3\_SLOW\_GCLK}}(\mathrm{OCP}) \geq f_{\mathrm{CANCLK}}$

NOTE: The CAN core has to be programmed to at least 8 clock cycles per bit time. To achieve a transfer rate of 1 MBaud when using the asynchronous clock domain as the clock source for CAN_CLK (CLK_M_OSC), an oscillator frequency of 8 MHz or higher has to be used.

25.3.10 Interrupt Functionality

Interrupts can be generated on two interrupt lines: DCANINT0 and DCANINT1. These lines can be enabled by setting the IE0 and IE1 bits, respectively, in the CTL register. The interrupts are level triggered at the chip level.

The DCAN provides three groups of interrupt sources: message object interrupts, status change interrupts, and error interrupts (see Figure 25-9 and Figure 25-10).

The source of an interrupt can be determined by the interrupt identifiers Int0ID/Int1ID in the interrupt register (see INT). When no interrupt is pending, the register will hold the value zero.

Each interrupt line remains active until the dedicated field (Int0ID or Int1ID) in the interrupt register (INT) again reach zero, meaning the cause of the interrupt is reset, or until IE0 or IE1 are reset.

The value 0x8000 in the Int0ID field indicates that an interrupt is pending because the CAN core has updated (not necessarily changed) the Error and Status register (ES). This interrupt has the highest priority. The CPU can update (reset) the status bits WakeUpPnd, RxOk, TxOk and LEC by reading the ES register, but a write access of the CPU will never generate or reset an interrupt.

Values between 1 and the number of the last message object indicates that the source of the interrupt is one of the message objects, Int0ID or Int1ID will point to the pending message interrupt with the highest priority. The Message Object 1 has the highest priority; the last message object has the lowest priority.

An interrupt service routine that reads the message that is the source of the interrupt may read the message and reset the message object’s IntPnd at the same time (ClrIntPnd bit in the IF1CMD or IF2CMD register). When IntPnd is cleared, the interrupt register will point to the next message object with a pending interrupt.

25.3.10.1 Message Object Interrupts

Message object interrupts are generated by events from the message objects. They are controlled by the flags IntPND, TxIE and RxIE that are described in Section 25.3.18.1.

Message object interrupts can be routed to either DCANINT0 or DCANINT1 line, controlled by the interrupt multiplexer register (INTMUX12 to INTMUX78).

25.3.10.2 Status Change Interrupts

The events WakeUpPnd, RxOk, TxOk and LEC in the ES register belong to the status change interrupts. The status change interrupt group can be enabled by bit in CTL register.

If SIE is set, a status change interrupt will be generated at each CAN frame, independent of bus errors or valid CAN communication, and also independent of the message RAM configuration.

Status change interrupts can only be routed to interrupt line DCAN0INT, which has to be enabled by setting the IE0 bit in the CTL register.

NOTE: Reading the error and status register will clear the WakeUpPnd flag. If in global power-down mode, the WakeUpPnd flag is cleared by such a read access before the DCAN module has been waken up by the system, the DCAN may re-assert the WakeUpPnd flag, and a second interrupt may occur.

25.3.10.3 Error Interrupts

The events PER, BOff and EWarn, monitored in the ES register, belong to the error interrupts. The error interrupt group can be enabled by setting the EIE bit in the CTL register.

Error interrupts can only be routed to interrupt line DCAN0INT, which has to be enabled by setting the IE0 bit in the CTL register.

Figure 25-9. CAN Interrupt Topology 1

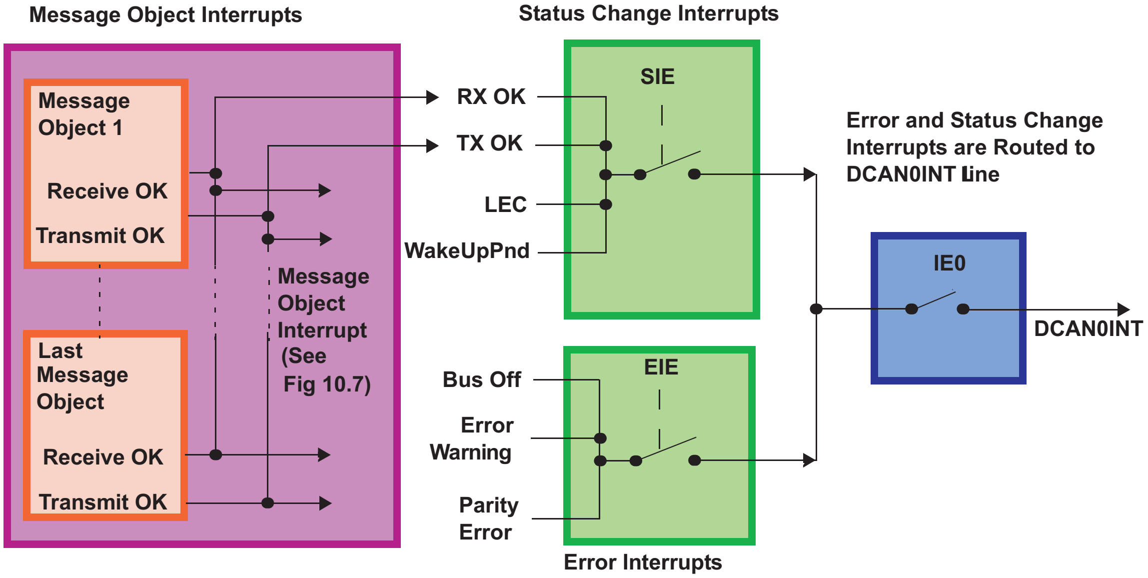


Figure 25-10. CAN Interrupt Topology 2

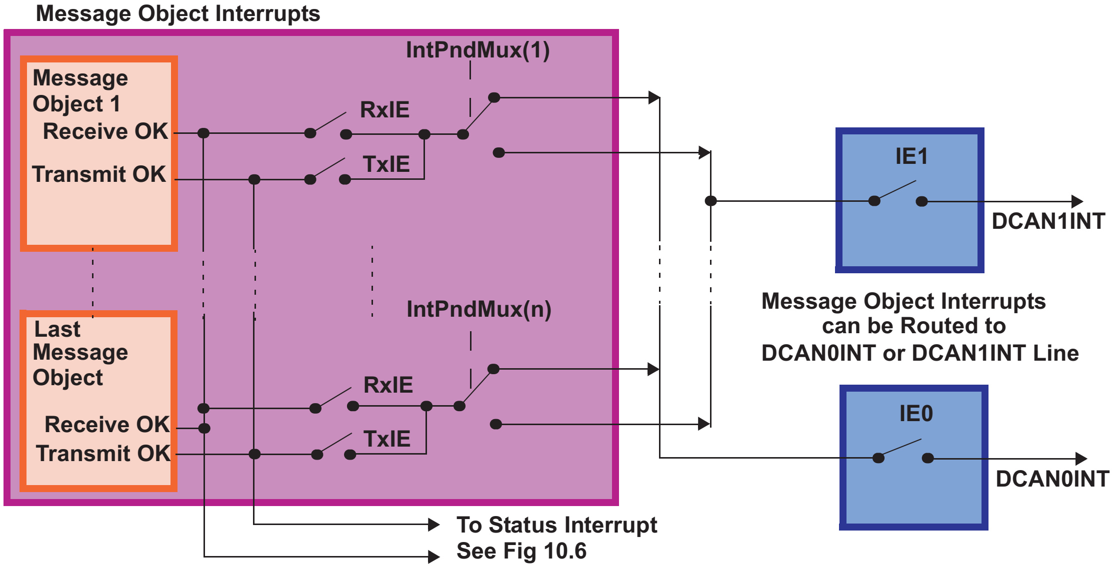


25.3.11 Local Power-Down Mode

The DCAN supports a local power-down mode, which can be controlled within the CTL register.

25.3.11.1 Entering Local Power-Down Mode

The local power-down mode is requested by setting the PDR bit in the CTL register.

The DCAN then finishes all transmit requests of the message objects. When all requests are done, the DCAN module waits until a bus idle state is recognized. The module will automatically set the Init bit in the CTL register to prevent any further CAN transfers, and it will also set the PDA bit in the CAN error and status register (ES). With setting the PDA bits, the DCAN module indicates that the local power-down mode has been entered.

During local power-down mode, the internal clocks of the DCAN module are turned off, but there is wakeup logic (see Section 25.3.11.2) that can be active, if enabled. Also, the actual contents of the control registers can be read back.

NOTE: In local low-power mode, the application should not clear the Init bit while PDR is set. If there are any messages in the message RAM which are configured as transmit messages and the application resets the init bit, these messages may get sent.

25.3.11.2 Wakeup From Local Power Down

There are two ways to wake up the DCAN from local power-down mode:

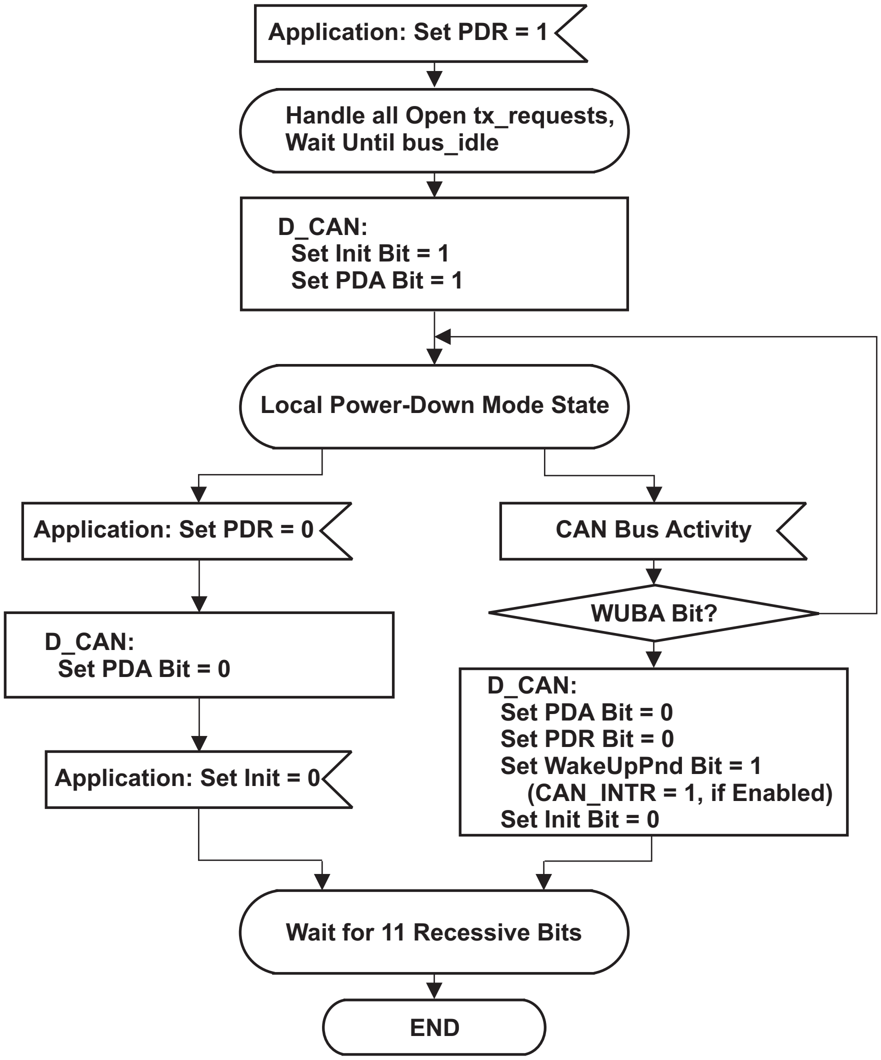
- The application could wake up the DCAN module manually by clearing the PDR bit and then clearing the Init bit in the CTL register.
- Alternatively, a CAN bus activity detection circuit can be activated by setting the wakeup on bus activity (WUBA) bit in the CTL register. If this circuit is active, on occurrence of a dominant CAN bus level, the DCAN will automatically start the wakeup sequence. It will clear the PDR bit in the CTL register and also clear the PDA bit in the error and status register. The WakeUpPnd bit in the ES register will be set. If status interrupts are enabled, also an interrupt will be generated. Finally the Init bit in the CTL register will be cleared.

After the Init bit has been cleared, the module waits until it detects 11 consecutive recessive bits on the CAN_RX pin and then goes bus-active again.

NOTE: The CAN transceiver circuit has to stay active in order to detect any CAN bus activity while the DCAN is in local power down mode. The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power-down and automatic wake-up mode, is lost.

Figure 25-11 shows a flow diagram about entering and leaving local power-down mode.

Figure 25-11. Local Power-Down Mode Flow Diagram



25.3.12 Parity Check Mechanism

The DCAN provides a parity check mechanism to ensure data integrity of message RAM data. For each word (32 bits) in message RAM, one parity bit will be calculated. The formation of the different words is according to the message RAM representation in RDA mode, see Section 25.3.18.4.

Parity information is stored in the message RAM on write accesses and will be checked against the stored parity bit from message RAM on read accesses.

The Parity check functionality can be enabled or disabled by PMD bit field in the CTL register.

In case of disabled parity check, the parity bits in message RAM will be left unchanged on write access to data area and no check will be done on read access.

If parity checking is enabled, parity bits will be automatically generated and checked by the DCAN. The parity bits could be read in debug/suspend mode (see Section 25.3.18.3) or in RDA mode (see Section 25.3.18.4). However, direct write access to the parity bits is only possible in these two modes with parity check disabled.

A parity bit will be set, if the modulo-2-sum of the data bits is 1. This definition is equivalent to: The parity bit will be set, if the number of 1 bits in the data is odd.

NOTE: The parity scheme is tied to even parity at the device level.

25.3.12.1 Behavior on Parity Error

On any read access to message RAM (e.g., during start of a CAN frame transmission), the parity of the message object will be checked. If a parity error is detected, the PER bit in the ES register will be set. If error interrupts are enabled, an interrupt would also be generated. In order to avoid the transmission of invalid data over the CAN bus, the D bit of the message object will be reset.

The message object data can be read by the host CPU, independently of parity errors. Thus, the application has to ensure that the read data is valid, for example, by immediately checking the parity error code register (PERR) on parity error interrupt.

NOTE: During RAM initialization, no parity check will be done.

25.3.12.2 Parity Testing

Testing the parity mechanism can be done by enabling the bit RamDirectAccess (RDA) and manually writing the parity bits directly to the dedicated RAM locations. With this, data and parity bits could be checked when reading directly from RAM.

NOTE: If parity check was disabled, the application has to ensure correct parity bit handling in order to prevent parity errors later on when parity check is enabled.

25.3.13 Debug/Suspend Mode

The module supports the usage of an external debug unit by providing functions like pausing DCAN activities and making message RAM content accessible via OCP interface.

Before entering debug/suspend mode, the circuit will either wait until a started transmission or reception will be finished and bus idle state is recognized, or immediately interrupt a current transmission or reception. This is depending on bit IDS in the CTL register.

Afterwards, the DCAN enters debug/suspend mode, indicated by InitDbg flag in the CTL register.

During debug/suspend mode, all DCAN registers can be accessed. Reading reserved bits will return ‘0’. Writing to reserved bits will have no effect.

Also, the message RAM will be memory mapped. This allows the external debug unit to read the message RAM. For the memory organization, see Section 25.3.18.3).

NOTE: During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

Writing to control registers in debug/suspend mode may influence the CAN state machine and further message handling.

For debug support, the auto clear functionality of the following DCAN registers is disabled:

- ES register (clear of status flags by read)
- IF1CMD and IF2CMD (clear of DMAActive flag by read/write)

25.3.14 Configuration of Message Objects

The whole message RAM should be configured before the end of the initialization, however it is also possible to change the configuration of message objects during CAN communication.

The CAN software driver library should offer subroutines that:

- Transfer a complete message structure into a message object. (Configuration)
- Transfer the data bytes of a message into a message object and set TxRqst and NewDat. (Start a new transmission)
- Get the data bytes of a message from a message object and clear NewDat (and IntPnd). (Read received data)
- Get the complete message from a message object and clear NewDat (and IntPnd). (Read a received message, including identifier, from a message object with UMask = ‘1’)

Parameters of the subroutines are the Message Number and a pointer to a complete message structure or to the data bytes of a message structure.

Two examples of assigning the IFx interface register sets to these subroutines are shown here:

In the first method, the tasks of the application program that may access the module are divided into two groups. Each group is restricted to the use of one of the interface register sets. The tasks of one group may interrupt tasks of the other group, but not of the same group.

In the second method, which may be a special case of the first method, there are only two tasks in the application program that access the module. A Read_Message task that uses IF2 or IF3 to get received messages from the message RAM and a Write_Message task that uses IF1 to write messages to be transmitted (or to be configured) into the message RAM. Both tasks may interrupt each other.

25.3.14.1 Configuration of a Transmit Object for Data Frames

Table 25-4 shows how a transmit object can be initialized.

Table 25-4. Initialization of a Transmit Object

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of the outgoing message. If an 11-bit identifier (standard frame) is used (Xtd = ‘0’), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored.

The data registers (DLC[3:0] and Data0-7) are given by the application. TxRqst and RmtEn should not be set before the data is valid.

If the TxIE bit is set, the IntPnd bit will be set after a successful transmission of the message object.

If the RmtEn bit is set, a matching received remote frame will cause the TxRqst bit to be set; the remote frame will autonomously be answered by a data frame.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask=’1’) to allow groups of remote frames with similar identifiers to set the TxRqst bit. The Dir bit should not be masked. For details, see Section 25.3.15.8. Identifier masking must be disabled (UMask = ‘0’) if no remote frames are allowed to set the TxRqst bit (RmtEn = ‘0’).

25.3.14.2 Configuration of a Transmit Object for Remote Frames

It is not necessary to configure transmit objects for the transmission of remote frames. Setting TxRqst for a receive object causes the transmission of a remote frame with the same identifier as the data frame for which this receive object is configured.

25.3.14.3 Configuration of a Single Receive Object for Data Frames

Table 25-5 shows how a receive object for data frames can be initialized.

Table 25-5. Initialization of a single Receive Object for Data Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	0

The arbitration bits (ID[28:0] and Xtd bit) are given by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier (standard frame) is used (Xtd = ‘0’), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a data frame with an 11-bit Identifier is received, ID[17:0] is set to ‘0’.

The data length code (DLC[3:0]) is given by the application. When the message handler stores a data frame in the message object, it will store the received data length code and eight data bytes. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by non specified values.

The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be used (UMask = ’1’) to allow groups of data frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. If some bits of the mask bits are set to “don’t care,” the corresponding bits of the arbitration register will be overwritten by the bits of the stored data frame.

If the RxIE bit is set, the IntPnd bit will be set when a received data frame is accepted and stored in the message object.

If the TxRqst bit is set, the transmission of a remote frame with the same identifier as actually stored in the arbitration bits will be triggered. The content of the arbitration bits may change if the mask bits are used (UMask = ’1’) for acceptance filtering.

25.3.14.4 Configuration of a Single Receive Object for Remote Frames

Table 25-6 shows how a receive object for remote frames can be initialized.

Table 25-6. Initialization of a Single Receive Object for Remote Frames

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	appl.	0	0	0	0

A receive object for remote frames may be used to monitor remote frames on the CAN bus. The remote frame stored in the receive object will not trigger the transmission of a data frame. Receive objects for remote frames may be expanded to a FIFO buffer (see Section 25.3.14.5).

UMask must be set to ‘1.’ The mask bits (Msk[28:0], UMask, MXtd, and MDir bits) may be set to “must-match” or to “don’t care,” to allow groups of remote frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications. For details, see Section 25.3.15.8.

The arbitration bits (ID[28:0] and Xtd bit) may be given by the application. They define the identifier and type of accepted received remote frames. If some bits of the mask bits are set to “don’t care,” the corresponding bits of the arbitration bits will be overwritten by the bits of the stored remote frame. If an 11-bit Identifier (standard frame) is used (Xtd = ‘0’), it is programmed to ID[28:18]. In this case, ID[17:0] can be ignored. When a remote frame with an 11-bit Identifier is received, ID[17:0] will be set to ‘0.’

The data length code (DLC[3:0]) may be given by the application. When the message handler stores a remote frame in the message object, it will store the received data length code. The data bytes of the message object will remain unchanged.

If the RxIE bit is set, the IntPnd bit will be set when a received remote frame is accepted and stored in the message object.

25.3.14.5 Configuration of a FIFO Buffer

With the exception of the EoB bit, the configuration of receive objects belonging to a FIFO buffer is the same as the configuration of a single receive object.

To concatenate multiple message objects to a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest number will be the first message object of the FIFO buffer. The EoB bit of all message objects of a FIFO buffer except the last one have to be programmed to zero. The EoB bits of the last message object of a FIFO Buffer is set to one, configuring it as the end of the block.

25.3.15 Message Handling

When initialization is finished, the DCAN module synchronizes itself to the traffic on the CAN bus. It does acceptance filtering on received messages and stores those frames that are accepted into the designated message objects. The application has to update the data of the messages to be transmitted and to enable and request their transmission. The transmission is requested automatically when a matching remote frame is received.

The application may read messages which are received and accepted. Messages that are not read before the next messages is accepted for the same message object will be overwritten.

Messages may be read interrupt-driven or after polling of NewDat.

25.3.15.1 Message Handler Overview

The message handler state machine controls the data transfer between the Rx/Tx shift register of the CAN core and the message RAM. It performs the following tasks:

- Data transfer from message RAM to CAN core (messages to be transmitted)
- Data transfer from CAN core to the message RAM (received messages)
- Data transfer from CAN core to the acceptance filtering unit
- Scanning of message RAM for a matching message object (acceptance filtering)
- Scanning the same message object after being changed by IF1/IF2 registers when priority is the same or higher as the message the object found by last scanning
- Handling of TxRqst flags
- Handling of interrupt flags

The message handler registers contains status flags of all message objects grouped into the following topics:

- Transmission Request Flags
- New Data Flags
- Interrupt Pending Flags
- Message Valid Registers

Instead of collecting above listed status information of each message object via IFx registers separately, these message handler registers provides a fast and easy way to get an overview, for example, about all pending transmission requests.

All message handler registers are read-only.

25.3.15.2 Receive/Transmit Priority

The receive/transmit priority for the message objects is attached to the message number, not to the CAN identifier. Message object 1 has the highest priority, while the last implemented message object has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding message object so messages with the highest priority, for example, can be placed in the message objects with the lowest numbers.

The acceptance filtering for received data frames or remote frames is also done in ascending order of message objects, so a frame that has been accepted by a message object cannot be accepted by another message object with a higher message number. The last message object may be configured to accept any data frame or remote frame that was not accepted by any other message object, for nodes that need to log the complete message traffic on the CAN bus.

25.3.15.3 Transmission of Messages in Event-Driven CAN Communication

If the shift register of the CAN core is ready for loading and if there is no data transfer between the IFx registers and message RAM, the D bits in the Message Valid register (MSGVAL12 to MSGVAL78) and the TxRqst bits in the transmission request register are evaluated. The valid message object with the highest priority pending transmission request is loaded into the shift register by the message handler and the transmission is started. The message object’s NewDat bit is reset.

After a successful transmission and if no new data was written to the message object (NewDat = ‘0’) since the start of the transmission, the TxRqst bit will be reset. If TxIE is set, IntPnd will be set after a successful transmission. If the DCAN module has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. If meanwhile the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

If automatic retransmission mode is disabled by setting the DAR bit in the CTL register, the behavior of bits TxRqst and NewDat in the Message Control register of the interface register set is as follows:

- When a transmission starts, the TxRqst bit of the respective interface register set is reset, while bit NewDat remains set.
- When the transmission has been successfully completed, the NewDat bit is reset.

When a transmission failed (lost arbitration or error) bit NewDat remains set. To restart the transmission, the application has to set TxRqst again.

Received remote frames do not require a receive object. They will automatically trigger the transmission of a data frame, if in the matching transmit object the RmtEn bit is set.

25.3.15.4 Updating a Transmit Object

The CPU may update the data bytes of a transmit object any time via the IF1 and IF2 interface registers, neither D nor TxRqst have to be reset before the update.

Even if only part of the data bytes is to be updated, all four bytes in the corresponding IF1 or IF2 Data A register (IF1DATA or IF2DATA) or IF1 or IF2 Data B register (IF1DATB or IF2DATB) have to be valid before the content of that register is transferred to the message object. Either the CPU has to write all four bytes into the IF1/IF2 data register or the message object is transferred to the IF1/IF2 data register before the CPU writes the new data bytes.

When only the data bytes are updated, first 0x87 can be written to bits [23:16] of the IF1 and IF2 Command register (IF1CMD and IF2CMD) and then the number of the message object is written to bits [7:0] of the command register, concurrently updating the data bytes and setting TxRqst with NewDat.

To prevent the reset of TxRqst at the end of a transmission that may already be in progress while the data is updated, NewDat has to be set together with TxRqst in event driven CAN communication. For details, see Section 25.3.15.3.

When NewDat is set together with TxRqst, NewDat will be reset as soon as the new transmission has started.

25.3.15.5 Changing a Transmit Object

If the number of implemented message objects is not sufficient to be used as permanent message objects only, the transmit objects may be managed dynamically. The CPU can write the whole message (arbitration, control, and data) into the interface register. The bits [23:16] of the command register can be set to 0xB7 for the transfer of the whole message object content into the message object. Neither D nor TxRqst have to be reset before this operation.

If a previously requested transmission of this message object is not completed but already in progress, it will be continued; however, it will not be repeated if it is disturbed.

To only update the data bytes of a message to be transmitted, bits [23:16] of the command register should be set to 0x87.

NOTE: After the update of the transmit object, the interface register set will contain a copy of the actual contents of the object, including the part that had not been updated.

25.3.15.6 Acceptance Filtering of Received Messages

When the arbitration and control bits (Identifier + IDE + RTR + DLC) of an incoming message are completely shifted into the shift register of the CAN core, the message handler starts the scan of the message RAM for a matching valid message object:

- The acceptance filtering unit is loaded with the arbitration bits from the CAN core shift register.
- Then the arbitration and mask bits (including MsgVal, UMask, NewDat, and EoB) of message object 1 are loaded into the acceptance filtering unit and are compared with the arbitration bits from the shift register. This is repeated for all following message objects until a matching message object is found, or until the end of the message RAM is reached.
- If a match occurs, the scanning is stopped and the message handler proceeds depending on the type of the frame (data frame or remote frame) received.

25.3.15.7 Reception of Data Frames

The message handler stores the message from the CAN core shift register into the respective message object in the message RAM. Not only the data bytes, but all arbitration bits and the data length code are stored into the corresponding message object. This ensures that the data bytes stay associated to the identifier even if arbitration mask registers are used.

The NewDat bit is set to indicate that new data (not yet seen by the CPU) has been received. The CPU should reset the NewDat bit when it reads the message object. If at the time of the reception the NewDat bit was already set, MsgLst is set to indicate that the previous data (supposedly not seen by the CPU) is lost. If the RxIE bit is set, the IntPnd bit is set, causing the interrupt register (INT) to point to this message object.

The TxRqst bit of this message object is reset to prevent the transmission of a remote frame, while the requested data frame has just been received.

25.3.15.8 Reception of Remote Frames

When a remote frame is received, three different configurations of the matching message object have to be considered:

- Dir = ‘1’ (direction = transmit), RmtEn = ‘1’, UMask = ‘1’ or ‘0’

  The TxRqst bit of this message object is set at the reception of a matching remote frame. The rest of the message object remains unchanged.
- Dir = ‘1’ (direction = transmit), RmtEn = ‘0’, UMask = ‘0’

  The remote frame is ignored, this message object remains unchanged.
- Dir = ‘1’ (direction = transmit), RmtEn = ‘0’, UMask = ‘1’

  The remote frame is treated similar to a received data frame. At the reception of a matching Remote Message Frame, the TxRqst bit of this message object is reset. The arbitration and control bits (Identifier + IDE + RTR + DLC) from the shift register are stored in the message object in the message RAM and the NewDat bit of this message object is set. The data bytes of the message object remain unchanged.

25.3.15.9 Reading Received Messages

The CPU may read a received message any time via the IFx interface register. The data consistency is guaranteed by the message handler state machine. Typically the CPU will write first 0x7F to bits [23:16] and then the number of the message object to bits [7:0] of the command register. That combination will transfer the entire received message from the message RAM into the interface register set. Additionally, the bits NewDat and IntPnd are cleared in the message RAM (not in the interface register set). The values of these bits in the message control register always reflect the status before resetting the bits. If the message object uses masks for acceptance filtering, the arbitration bits show which of the different matching messages has been received.

The actual value of NewDat shows whether a new message has been received since last time when this message object was read. The actual value of MsgLst shows whether more than one message has been received since the last time when this message object was read. MsgLst will not be automatically reset.

25.3.15.10 Requesting New Data for a Receive Object

By means of a remote frame, the CPU may request another CAN node to provide new data for a receive object. Setting the TxRqst bit of a receive object will cause the transmission of a remote frame with the identifier of the receive object. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the TxRqst bit is automatically reset. Setting the TxRqst bit without changing the contents of a message object requires the value 0x84 in bits [23:16] of the IFxCMD register.

25.3.15.11 Storing Received Messages in FIFO Buffers

Several message objects may be grouped to form one or more FIFO buffers. Each FIFO buffer configured to store received messages with a particular (group of) identifier(s). Arbitration and mask registers of the FIFO buffer's message objects are identical. The end of buffer (EoB) bits of all but the last of the FIFO buffer's message objects are '0'; in the last one the EoB bit is '1.'

Received messages with identifiers matching to a FIFO buffer are stored into a message object of this FIFO buffer, starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the NewDat bit of this message object is set. By setting NewDat while EoB is '0', the message object is locked for further write accesses by the message handler until the CPU has cleared the NewDat bit.

Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. If none of the preceding message objects is released by writing NewDat to '0,' all further messages for this FIFO buffer will be written into the last message object of the FIFO buffer (EoB = '1') and therefore overwrite previous messages in this message object.

25.3.15.12 Reading From a FIFO Buffer

Several messages may be accumulated in a set of message objects which are concatenated to form a FIFO buffer before the application program is required (in order to avoid the loss of data) to empty the buffer.

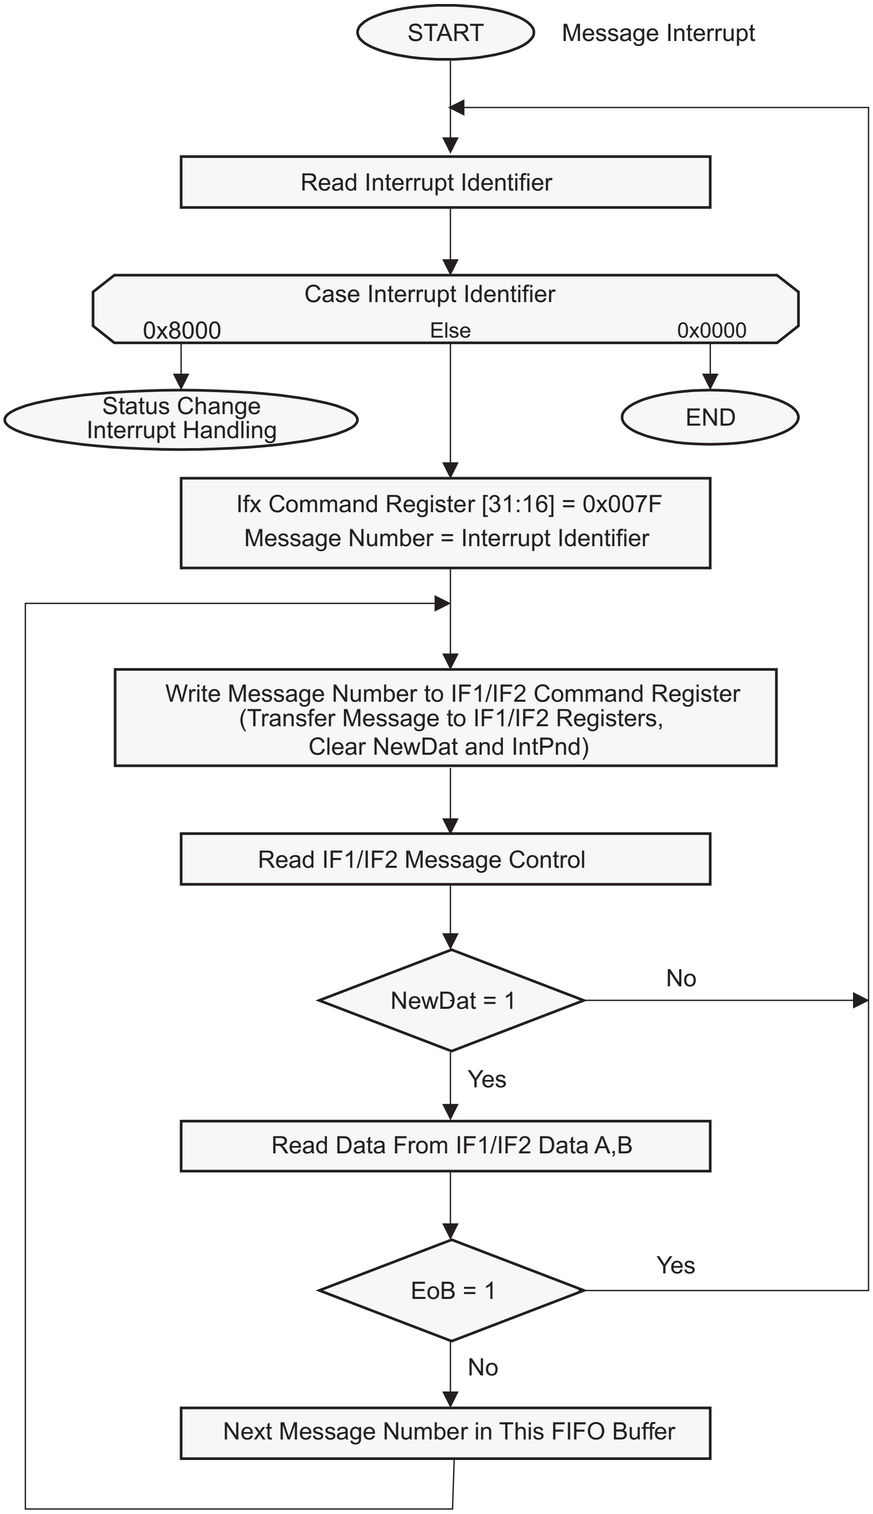
A FIFO buffer of length N will store –1 plus the last received message since last time it was cleared.

A FIFO buffer is cleared by reading and resetting the NewDat bits of all its message objects, starting at the FIFO Object with the lowest message number. This should be done in a subroutine following the example shown in Figure 25-12.

NOTE: All message objects of a FIFO buffer need to be read and cleared before the next batch of messages can be stored. Otherwise, true FIFO functionality can not be guaranteed, since the message objects of a partly read buffer will be re-filled according to the normal (descending) priority.

Reading from a FIFO buffer message object and resetting its NewDat bit is handled the same way as reading from a single message object.

Figure 25-12. CPU Handling of a FIFO Buffer (Interrupt Driven)



25.3.16 CAN Bit Timing

The DCAN supports bit rates between less than 1 kBit/s and 1000 kBit/s.

Each member of the CAN network has its own clock generator, typically derived from a crystal oscillator. The bit timing parameters can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods (f_{osc}) may be different.

The frequencies of these oscillators are not absolutely stable. Small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range (df), the CAN nodes are able to compensate for the different bit rates by resynchronizing to the bit stream.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

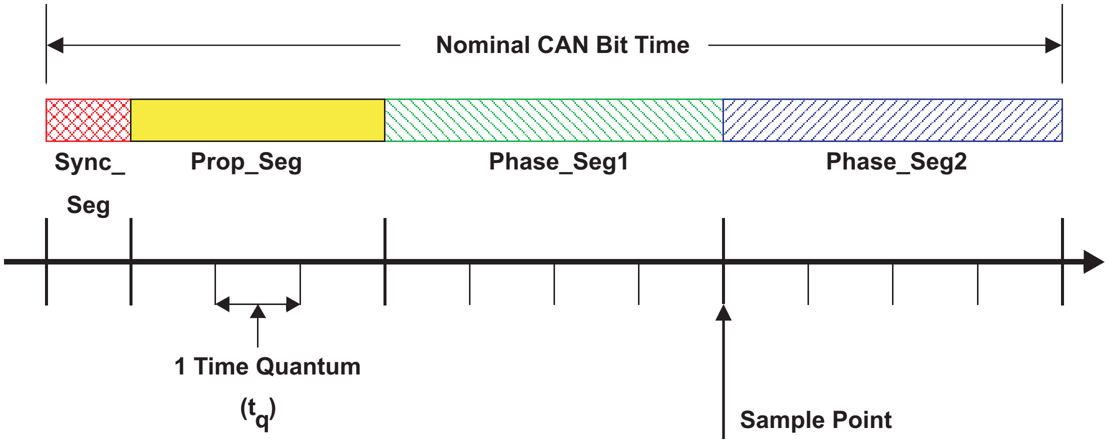
Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

25.3.16.1 Bit Time and Bit Rate

According to the CAN specification, the bit time is divided into four segments (see Figure 25-13):

- Synchronization segment (Sync_Seg)
- Propagation time segment (Prop_Seg)
- Phase buffer segment 1 (Phase_Seg1)
- Phase buffer segment 2 (Phase_Seg2)

Figure 25-13. Bit Timing



Each segment consists of a specific number of time quanta. The length of one time quantum (t_q), which is the basic time unit of the bit time, is given by the CAN_CLK and the baud rate prescalers (BRPE and BRP). With these two baud rate prescalers combined, divider values from 1 to 1024 can be programmed:

t_q = Baud Rate Prescaler / CAN_CLK

Apart from the fixed length of the synchronization segment, these numbers are programmable. Table 25-7 describes the minimum programmable ranges required by the CAN protocol.

A given bit rate may be met by different bit time configurations.

Table 25-7. Parameters of the CAN Bit Time

Parameter	Range	Remark
Sync_Seg	1 t_q (fixed)	Synchronization of bus input to CAN_CLK
Prop_Seg	[1 … 8] t_q	Compensates for the physical delay times
Phase_Seg1	[1 … 8] t_q	May be lengthened temporarily by synchronization
Phase_Seg2	[1 … 8] t_q	May be shortened temporarily by synchronization
Synchronization Jump Width (SJW)	[1 … 4] t_q	May not be longer than either Phase Buffer Segment

NOTE: For proper functionality of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

25.3.16.1.1 Synchronization Segment

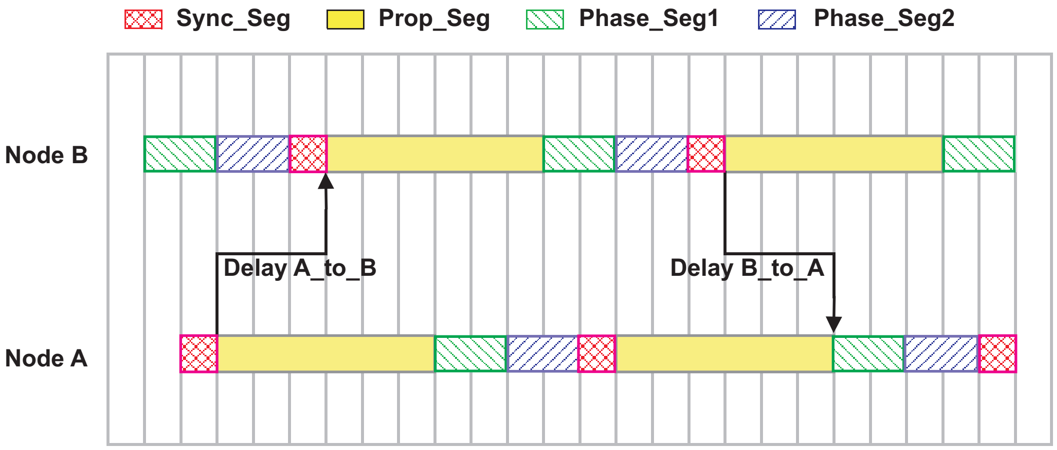
The synchronization segment (Sync_Seg) is the part of the bit time where edges of the CAN bus level are expected to occur. If an edge occurs outside of Sync_Seg, its distance to the Sync_Seg is called the phase error of this edge.

25.3.16.1.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the CAN network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus can be out of phase with the transmitter of the bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's nondestructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages require that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 25-14 shows the phase shift and propagation times between two CAN nodes.

Figure 25-14. The Propagation Time Segment



Delay A_to_B >= node output delay(A) + bus line delay(AÆB) + node input delay(B)

Prop_Seg >= Delay A_to_B + Delay B_to_A

Prop_Seg >= 2 • [max(node output delay+bus line delay + node input delay)]

In this example, both nodes A and B are transmitters performing an arbitration for the CAN bus. The node A has sent its start of frame bit less than one bit time earlier than node B, therefore node B has synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay(A_to_B) after it has been transmitted, node B's bit timing segments are shifted with regard to node A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay (B_to_A).

Due to oscillator tolerances, the actual position of node A's sample point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase_Seg1. This condition defines the length of Prop_Seg.

If the edge from recessive to dominant transmitted by node B would arrive at node A after the start of Phase_Seg1, it could happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

This error only occurs when two nodes arbitrate for the CAN bus which have oscillators of opposite ends of the tolerance range and are separated by a long bus line; this is an example of a minor error in the bit timing configuration (Prop_Seg too short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3 Sample Mode. The DCAN does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of 1 t_q, requiring a longer Prop_Seg.

25.3.16.1.3 Phase Buffer Segments and Synchronization

The phase buffer segments (Phase_Seg1 and Phase_Seg2) and the synchronization jump width (SJW) are used to compensate for the oscillator tolerance.

The phase buffer segments surround the sample point and may be lengthened or shortened by synchronization.

The synchronization jump width (SJW) defines how far the resynchronizing mechanism may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

Synchronizations occur on edges from recessive to dominant. Their purpose is to control the distance between edges and sample points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous sample point. A synchronization may be done only if a recessive bit was sampled at the previous sample point and if the actual time quantum's bus level is dominant.

An edge is synchronous if it occurs inside of Sync_Seg; otherwise, its distance to the Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist: hard synchronization and resynchronizing. A hard synchronization is done once at the start of a frame; inside a frame, only resynchronization is possible.

- Hard Synchronization

  After a hard synchronization, the bit time is restarted with the end of Sync_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge which has caused the hard synchronization, to lie within the synchronization segment of the restarted bit time.

- Bit Resynchronizations

  Resynchronization leads to a shortening or lengthening of the Bit time such that the position of the sample point is shifted with regard to the edge.

  When the phase error of the edge which causes resynchronization is positive, Phase_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

  When the phase error of the edge which causes Resynchronization is negative, Phase_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

If the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of hard synchronization and resynchronization are the same. If the magnitude of the phase error is larger than SJW, the resynchronization cannot compensate the phase error completely, and an error of (phase error - SJW) remains.

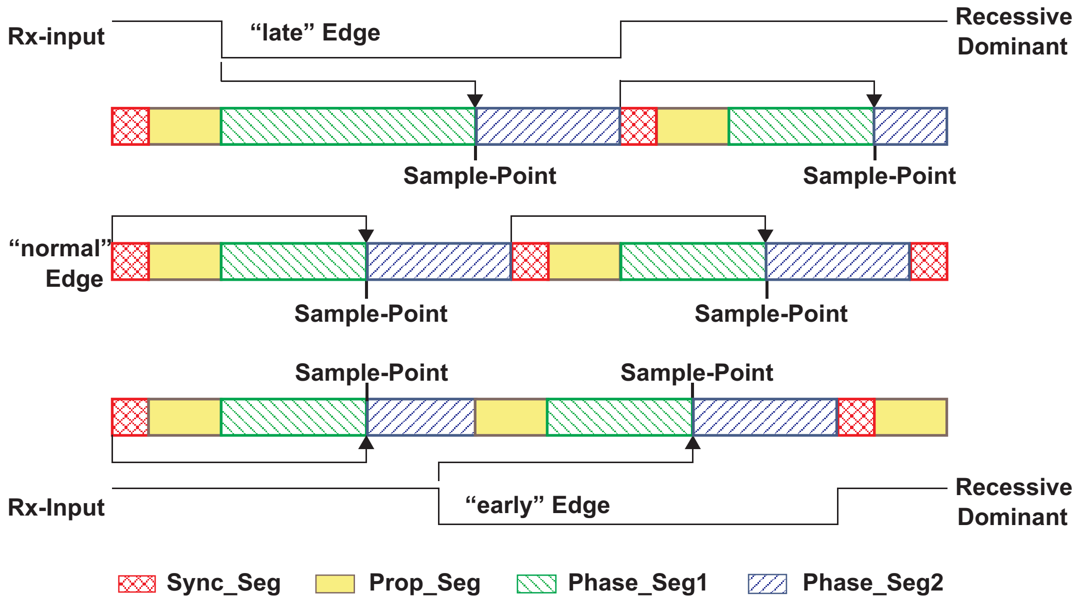
Only one synchronization may be done between two sample points. The synchronizations maintain a minimum distance between edges and sample points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop_Seg + Phase_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize “hard” on the edge transmitted by the “leading” transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The leading transmitter does not necessarily win the arbitration; therefore, the receivers have to synchronize themselves to different transmitters that subsequently take the lead and that are differently synchronized to the previously leading transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that takes the lead in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator’s clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator’s tolerance range.

Figure 25-15 shows how the phase buffer segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a “late” edge, the lower drawing shows the synchronization on an “early” edge, and the middle drawing is the reference without synchronization.

Figure 25-15. Synchronization on Late and Early Edges



In the first example, an edge from recessive to dominant occurs at the end of Prop_Seg. The edge is "late" since it occurs after the Sync_Seg. Reacting to the late edge, Phase_Seg1 is lengthened so that the distance from the edge to the sample point is the same as it would have been from the Sync_Seg to the sample point if no edge had occurred. The phase error of this late edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync_Seg.

In the second example, an edge from recessive to dominant occurs during Phase_Seg2. The edge is "early" since it occurs before a Sync_Seg. Reacting to the early edge, Phase_Seg2 is shortened and Sync_Seg is omitted, so that the distance from the edge to the sample point is the same as it would have been from a Sync_Seg to the sample point if no edge had occurred. As in the previous example, the magnitude of this early edge’s phase error is less than SJW, so it is fully compensated.

The phase buffer segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

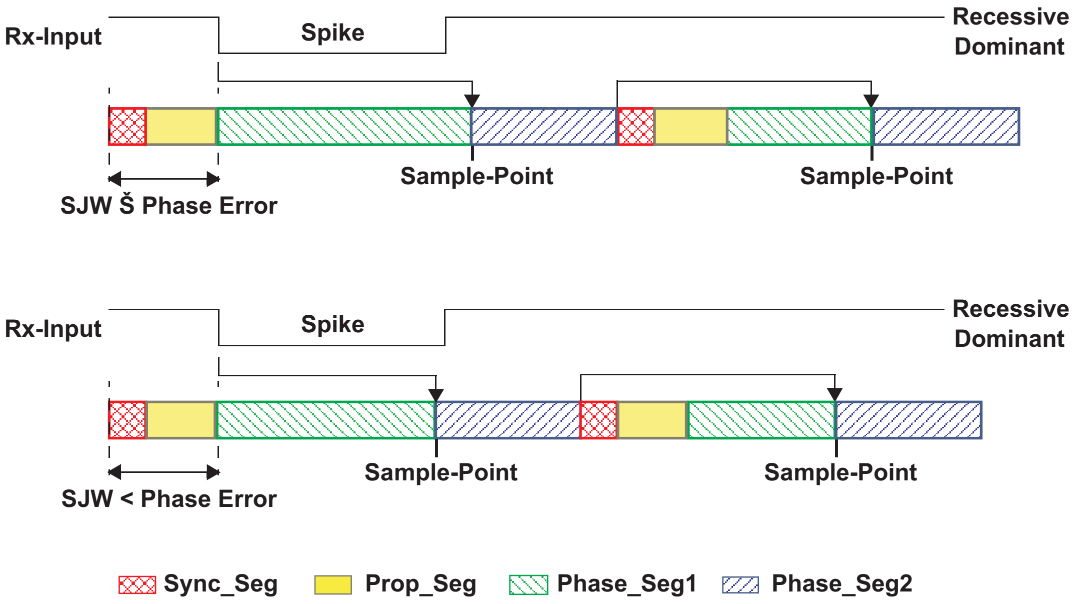
In these examples, the bit timing is seen from the point of view of the CAN implementation's state machine, where the bit time starts and ends at the sample points. The state machine omits Sync_Seg when synchronizing on an early edge because it cannot subsequently redefine that time quantum of Phase_Seg2 where the edge occurs to be the Sync_Seg.

Figure 25-16 shows how short dominant noise spikes are filtered by synchronizations. In both examples, the spike starts at the end of Prop_Seg and has the length of (Prop_Seg + Phase_Seg1).

In the first example, the synchronization jump width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the sample point is shifted after the end of the spike; a recessive bus level is sampled.

In the second example, SJW is shorter than the phase error, so the sample point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

Figure 25-16. Filtering of Short Dominant Spikes



25.3.16.1.4 *Oscillator Tolerance Range*

With the introduction of CAN protocol version 1.2, the option to synchronize on edges from dominant to recessive became obsolete. Only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator's frequency f_{osc} around the nominal frequency f_{nom} with:

$$(1 - df) \bullet f_{nom} \leq f_{osc} \leq (1 + df) \bullet f_{nom}$$

depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is the defined by two conditions (both shall be met):

$$\text{I:} \quad df \leq \frac{\min(TSeg1, TSeg2)}{2x(13x(bit\_time - TSeg2))}$$

$$\text{II:} \quad df \leq \frac{SJW}{20xbit\_time}$$

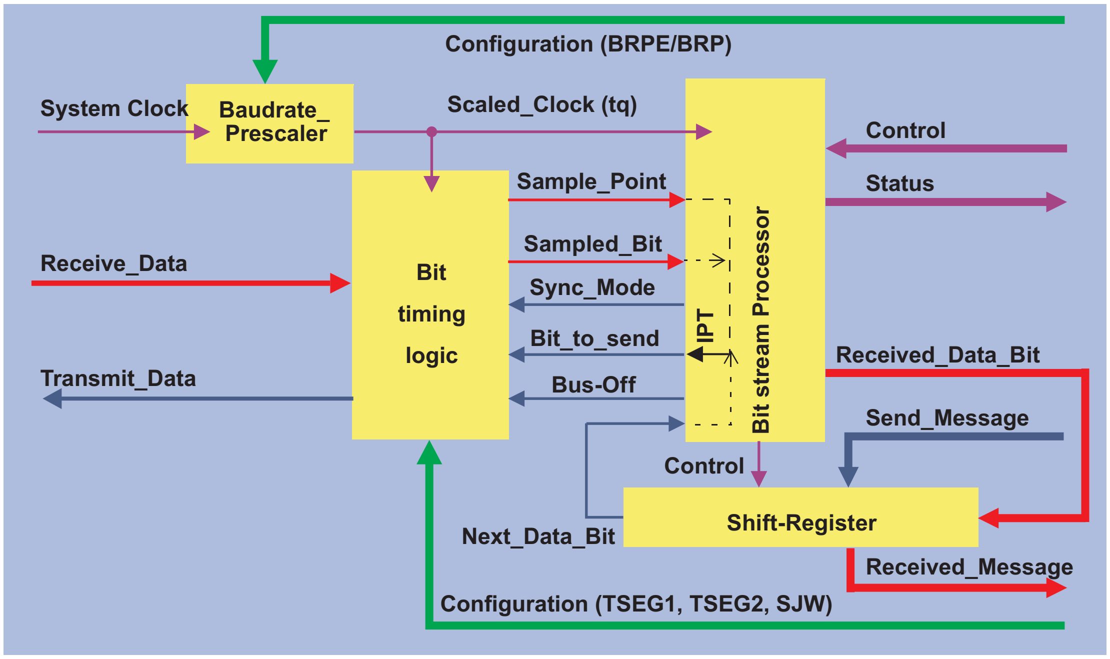
It has to be considered that SJW may not be larger than the smaller of the phase buffer segments and that the propagation time segment limits that part of the bit time that may be used for the phase buffer segments.

The combination Prop_Seg = 1 and Phase_Seg1 = Phase_Seg2 = SJW = 4 allows the largest possible oscillator tolerance of 1.58%. This combination with a propagation time segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125 kBit/s (bit time = 8 μs) with a bus length of 40 m.

25.3.16.2 DCAN Bit Timing Registers

In the DCAN, the bit timing configuration is programmed in two register bytes, additionally a third byte for a baud rate prescaler extension of four bits (BREP) is provided. The sum of Prop_Seg and Phase_Seg1 (as TSEG1) is combined with Phase_Seg2 (as TSEG2) in one byte, SJW and BRP (plus BRPE in third byte) are combined in the other byte (see Figure 25-17).

Figure 25-17. Structure of the CAN Core's CAN Protocol Controller



In this bit timing register, the components TSEG1, TSEG2, SJW and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1…n], values in the range of [0…–1] are programmed. That way, e.g., SJW (functional range of [1…4]) is represented by only two bits.

Therefore, the length of the bit time is (programmed values) [TSEG1 + TSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q.

The data in the bit timing register (BTR) is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by BRPE/BRP) defines the length of the time quantum (the basic time unit of the bit time); the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the bit timing state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the bit stream processor (BSP) state machine, is evaluated once each bit time, at the sample point.

The shift register serializes the messages to be sent and parallelizes received messages. Its loading and shifting is controlled by the BSP. The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the sample point and processes the sampled bus input bit. The time after the sample point that is needed to calculate the next bit to be sent (e.g., data bit, CRC bit, stuff bit, error flag, or idle) is called the information processing time (IPT), which is 0 tq for the DCAN.

Generally, the IPT is CAN controller-specific, but may not be longer than 2 tq. The IPC length is the lower limit of the programmed length of Phase_Seg2. In case of a synchronization, Phase_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

25.3.16.2.1 Calculation of the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting bit time (1 / Bit rate) must be an integer multiple of the CAN clock period.

NOTE: 8 MHz is the minimum CAN clock frequency required to operate the DCAN at a bit rate of 1 MBit/s.

The bit time may consist of 8 to 25 time quanta. The length of the time quantum t_q is defined by the baud rate prescaler with t_q = (Baud Rate Prescaler) / CAN_CLK. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

First part of the bit time to be defined is the Prop_Seg. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of t_q).

The Sync_Seg is 1 t_q long (fixed), leaving (bit time – Prop_Seg – 1) t_q for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1, else Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 may not be shorter than any CAN controller’s Information Processing Time in the network, which is device dependent and can be in the range of [0…2] t_q.

The length of the synchronization jump width is set to its maximum value, which is the minimum of four (4) and Phase_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in Section 25.3.16.2.3.

If more than one configurations are possible to reach a certain Bit rate, it is recommended to choose the configuration which allows the highest oscillator tolerance range.

CAN nodes with different clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system’s oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies’ stability has to be increased in order to find a protocol compliant configuration of the CAN bit timing.

The resulting configuration is written into the bit timing register:

Tseg2 = Phase_Seg2-1

Tseg1 = Phase_Seg1+ Prop_Seg-1

SJW = SynchronizationJumpWidth-1

BRP = Prescaler-1

25.3.16.2.2 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN_CLK is 10 MHz, BRP is 0, the bit rate is 1 MBit/s.

t_q	100 ns	=	t_{CAN_CLK}
delay of bus driver	60 ns	=	
delay of receiver circuit	40 ns	=	
delay of bus line (40 m)	220 ns	=	
t_{Prop}	700 ns	=	INT (2*delays + 1) = 7 • t_q
t_{SJW}	100 ns	=	1 • t_q
t_{TSeg1}	800 ns	=	$t_{Prop} + t_{SJW}$
t_{TSeg2}	100 ns	=	Information Processing Time + 1 • t_q
$t_{Sync\text{-}Seg}$	100 ns	=	1 • t_q
bit time	1000 ns	=	$t_{Sync\text{-}Seg} + t_{TSeg1} + t_{TSeg2}$
tolerance for CAN_CLK	0.43 %	=	$\frac{(\min(TSeg1, TSeg2))}{2x(13x(bit\_time - TSeg2))}$
		=	$\frac{0.1\,\mu s}{2x(13x(1\,\mu s - 0.1\,\mu s))}$

In this example, the concatenated bit time parameters are $(1\text{-}1)_3\&(8\text{-}1)_4\&(1\text{-}1)_2\&(1\text{-}1)_6$, so the bit timing register is programmed to = 00000700.

25.3.16.2.3 Example for Bit Timing at Low Baud Rate

In this example, the frequency of CAN_CLK is 2 MHz, BRP is 1, the bit rate is 100 KBit/s.

t_q	1 µs	=	t_{CAN_CLK}
Delay of bus driver	200 ns	=	
Delay of receiver circuit	80 ns	=	
Delay of bus line (40 m)	220 ns	=	
t_{Prop}	1 µs	=	1 • t_q
t_{SJW}	4 µs	=	4 • t_q
t_{TSeg1}	5 µs	=	$t_{Prop} + t_{SJW}$
t_{TSeg2}	3 µs	=	Information Processing Time + 3 • t_q
$t_{Sync\text{-}Seg}$	1 µs	=	1 • t_q
Bit time	9 µs	=	$t_{Sync\text{-}Seg} + t_{TSeg1} + t_{TSeg2}$
Tolerance for CAN_CLK		=	$\frac{(\min(TSeg1, TSeg2))}{2x(13x(bit\_time - TSeg2))}$
		=	$\frac{0.1\,\mu s}{2x(13x(1\,\mu s - 0.1\,\mu s))}$

In this example, the concatenated bit time parameters are $(3\text{-}1)_3\&(5\text{-}1)_4\&(4\text{-}1)_2\&(2\text{-}1)_6$, so the bit timing register is programmed to = 0x000024C1.

25.3.17 Message Interface Register Sets

The interface register sets control the CPU read and write accesses to the message RAM. There are two interface registers sets for read/write access, IF1 and IF2 and one interface register set for read access only, IF3.

Due to the structure of the message RAM, it is not possible to change single bits or bytes of a message object. Instead, always a complete message object in the message RAM is accessed. Therefore the data transfer from the IF1/IF2 registers to the message RAM requires the message handler to perform a read-modify-write cycle: First those parts of the message object that are not to be changed are read from the message RAM into the interface register set, and after the update the whole content of the interface register set is written into the message object.

After the partial write of a message object, those parts of the interface register set that are not selected in the command register, will be set to the actual contents of the selected message object.

After the partial read of a message object, those parts of the interface register set that are not selected in the command register, will be left unchanged.

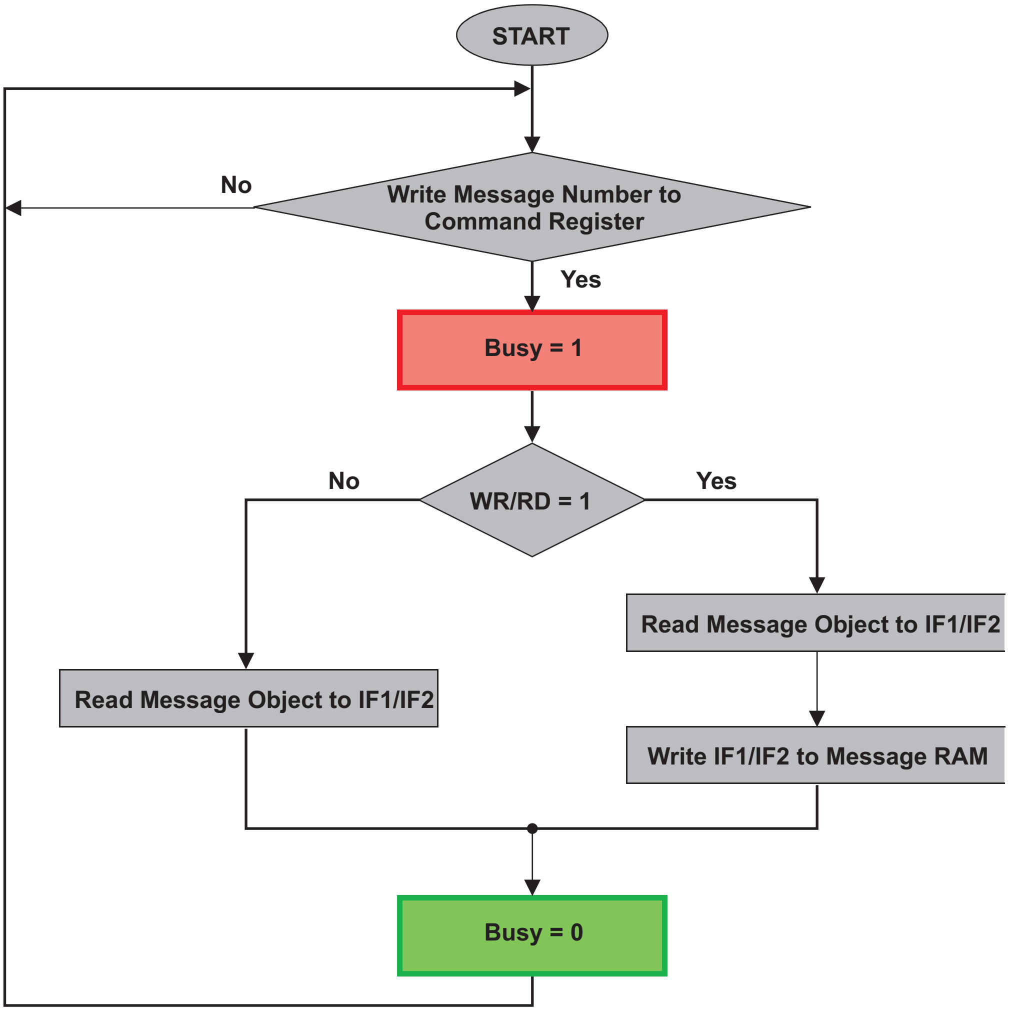
By buffering the data to be transferred, the interface register sets avoid conflicts between concurrent CPU accesses to the message RAM and CAN message reception and transmission. A complete message object (see Section 25.3.18.1) or parts of the message object may be transferred between the message RAM and the IF1/IF2 register set (see) in one single transfer. This transfer, performed in parallel on all selected parts of the message object, guarantees the data consistency of the CAN message.

25.3.17.1 Message Interface Register Sets 1 and 2

The IF1 and IF2 register sets control the data transfer to and from the message object. The IF1CMD and IF2CMD registers address the desired message object in the message RAM and specify whether a complete message object or only parts should be transferred. The data transfer is initiated by writing the message number to the bits [7:0] of the IF1CMD and IF2CMD register.

When the CPU initiates a data transfer between the IF1/IF2 registers and message RAM, the message handler sets the busy bit in the respective command register to ‘1’. After the transfer has completed, the busy bit is set back to ‘0’ (see Figure 25-18).

Figure 25-18. Data Transfer Between IF1/IF2 Registers and Message RAM



25.3.17.2 IF3 Register Set

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by CPU. The intention of this feature of IF3 is to provide an interface for the DMA to read packets efficiently. The automatic update functionality can be programmed for each message object using the update enable registers IF3UPD12 to IF3UPD78.

All valid message objects in message RAM which are configured for automatic update, will be checked for active NewDat flags. If such a message object is found, it will be transferred to the IF3 register (if no previous DMA transfers are ongoing), controlled by IF3 Observation register (IF3OBS). If more than one NewDat flag is active, the message object with the lowest number has the highest priority for automatic IF3 update.

The NewDat bit in the message object will be reset by a transfer to IF3.

If DCAN internal IF3 update is complete, a DMA request is generated. The DMA request stays active until first read access to one of the IF3 registers. The DMA functionality has to be enabled by setting bit DE3 in the CTL register. Please refer to the device datasheet to find out if this DMA source is available.

NOTE: The IF3 register set can not be used for transferring data into message objects.

25.3.18 Message RAM

The DCAN message RAM contains message objects and parity bits for the message objects. There are up to 64 message objects in the message RAM.

During normal operation, accesses to the message RAM are performed via the interface register sets, and the CPU cannot directly access the message RAM.

The interface register sets IF1 and IF2 provide indirect read/write access from the CPU to the message RAM. The IF1 and IF2 register sets can buffer control and user data to be transferred to and from the message objects.

The third interface register set IF3 can be configured to automatically receive control and user data from the message RAM when a message object has been updated after reception of a CAN message. The CPU does not need to initiate the transfer from message RAM to IF3 register set.

The message handler avoids potential conflicts between concurrent accesses to message RAM and CAN frame reception/transmission.

There are two modes where the message RAM can be directly accessed by the CPU:

- Debug/Suspend mode (see Section 25.3.18.3)
- RAM Direct Access (RDA) mode (see Section 25.3.18.4)

25.3.18.1 Structure of Message Objects

Table 25-8 shows the structure of a message object.

The grayed fields are those parts of the message object which are represented in dedicated registers. For example, the transmit request flags of all message objects are represented in centralized transmit request registers.

Table 25-8. Structure of a Message Object

Message Object												
UMask	**Msk[28:0]**	**MXtd**	**MDir**	**EoB**	**unused**	**NewDat**	**MsgLst**	**RxIE**	**TxIE**	**IntPnd**	**RmtEn**	**TxRqst**
MsgVal	ID[28:0]	Xtd	Dir	DLC[3:0]	Data 0	Data 1	Data 2	Data 3	Data 4	Data 5	Data 6	Data 7

Table 25-9. Field Descriptions

Name	Value	Description
MsgVal		Message valid
	0	The message object is ignored by the message handler.
	1	The message object is to be used by the message handler.
		Note: This bit may be kept at level ‘1’ even when the identifier bits ID[28:0], the control bits Xtd, Dir, or the data length code are changed. It should be reset if the Messages Object is no longer required.
UMask		Use acceptance mask
	0	Mask bits (Msk[28:0], MXtd and MDir) are ignored and not used for acceptance filtering.
	1	Mask bits are used for acceptance filtering.
		Note: If the UMask bit is set to one, the message object’s mask bits have to be programmed during initialization of the message object before MsgVal is set to one.
ID[28:0]		Message identifier
	ID[28:0]	29-bit (“extended”) identifier bits
	ID[28:18]	11-bit (“standard”) identifier bits
Msk[28:0]		Identifier mask
	0	The corresponding bit in the message identifier is not used for acceptance filtering (don’t care).
	1	The corresponding bit in the message identifier is used for acceptance filtering.
Xtd		Mask extended identifier
	0	The extended identifier bit (IDE) has no effect on the acceptance filtering.
	1	The extended identifier bit (IDE) is used for acceptance filtering.
		Note: When 11-bit (“standard”) Identifiers are used for a message object, the identifiers of received data frames are written into bits ID[28:18]. For acceptance filtering, only these bits together with mask bits Msk[28:18] are considered.
Dir		Message direction
	0	Direction = receive: On TxRqst, a remote frame with the identifier of this message object is transmitted. On reception of a data frame with matching identifier, the message is stored in this message object.
	1	Direction = transmit: On TxRqst, a data frame is transmitted. On reception of a remote frame with matching identifier, the TxRqst bit of this message object is set (if RmtEn = one).
MDir		Mask message direction
	0	The message direction bit (Dir) has no effect on the acceptance filtering.
	1	The message direction bit (Dir) is used for acceptance filtering.
EOB		End of block
	0	The message object is part of a FIFO Buffer block and is not the last message object of this FIFO Buffer block.
	1	The message object is a single message object or the last message object in a FIFO Buffer Block.
		Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one.

Table 25-9. Field Descriptions (continued)

Name	Value	Description
NewDat		New data
	0	No new data has been written into the data bytes of this message object by the message handler since the last time when this flag was cleared by the CPU.
	1	The message handler or the CPU has written new data into the data bytes of this message object.
MsgLst		Message lost (only valid for message objects with direction = receive)
	0	No message was lost since the last time when this bit was reset by the CPU.
	1	The message handler stored a new message into this message object when NewDat was still set, so the previous message has been overwritten.
RxIE		Receive interrupt enable
	0	IntPnd will not be triggered after the successful reception of a frame.
	1	IntPnd will be triggered after the successful reception of a frame.
TxIE		Transmit interrupt enable
	0	IntPnd will not be triggered after the successful transmission of a frame.
	1	IntPnd will be triggered after the successful transmission of a frame.
IntPnd		Interrupt pending
	0	This message object is not the source of an interrupt.
	1	This message object is the source of an interrupt. The interrupt Identifier in the interrupt register will point to this message object if there is no other interrupt source with higher priority.
RmtEn		Remote enable
	0	At the reception of a remote frame, TxRqst is not changed.
	1	At the reception of a remote frame, TxRqst is set.
TxRqst		Transmit request
	0	This message object is not waiting for a transmission.
	1	The transmission of this message object is requested and is not yet done.
DLC[3:0]		Data length code
	0	Data frame has 0 to 8 data bytes.
	1	Data frame has 8 data bytes.
		Note: The data length code of a message object must be defined to the same value as in the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.
Data 0		1st data byte of a CAN data frame
Data 1		2nd data byte of a CAN data frame
Data 2		3rd data byte of a CAN data frame
Data 3		4th data byte of a CAN data frame
Data 4		5th data byte of a CAN data frame
Data 5		6th data byte of a CAN data frame
Data 6		7th data byte of a CAN data frame
Data 7		8th data byte of a CAN data frame
		Note: Byte Data 0 is the first data byte shifted into the shift register of the CAN core during a reception, byte Data 7 is the last. When the message handler stores a data frame, it will write all the eight data bytes into a message object. If the data length code is less than 8, the remaining bytes of the message object may be overwritten by undefined values.

25.3.18.2 Addressing Message Objects in RAM

The starting location of a particular message object in RAM is:
Message RAM base address + (message object number) * 0x20

This means that message object 1 starts at offset 0x0020; message object 2 starts at offset 0x0040, etc.

‘0’ is not a valid message object number.

The base address for DCAN0 RAM is 0x481C_D000 and DCAN1 RAM is 0x481D_1000.

Message object number 1 has the highest priority.

Table 25-10. Message RAM addressing in Debug/Suspend and RDA Mode

Message Object Number	Offset From Base Address	Word Number	Debug/Suspend Mode, see Section 25.3.18.3	RDA mode, see Section 25.3.18.4
1	0x0020	1	Parity	Data Bytes 4-7
	0x0024	2	MXtd,MDir,Mask	Data Bytes 0-3
	0x0028	3	Xtd,Dir,ID	ID[27:0],DLC
	0x002C	4	Ctrl	Mask,Xtd,Dir,ID[28]

	0x07EC	4	Ctrl	Mask,Xtd,Dir,ID[28]
	0x07F0	5	Data Bytes 3-0	Parity,Ctrl,MXtd,MDir
	0x07F4	6	Data Bytes 7-4	…
last implemented (32(DCAN3) or 64)	0x0000	1	Parity	Data Bytes 4-7
	0x0004	2	MXtd,MDir,Mask	Data Bytes 0-3
	0x0008	3	Xtd,Dir,ID	ID[27:0],DLC
	0x000C	4	Ctrl	Mask,Xtd,Dir,ID[28]
	0x0010	5	Data Bytes 3-0	Parity,Ctrl,MXtd,MDir
	0x0014	6	Data Bytes 7-4	…

25.3.18.3 Message RAM Representation in Debug/Suspend Mode

In debug/suspend mode, the message RAM will be memory mapped. This allows the external debug unit to access the message RAM.

NOTE: During debug/suspend mode, the message RAM cannot be accessed via the IFx register sets.

Table 25-11. Message RAM Representation in Debug/Suspend Mode

Bit #	31/ 15	30/ 14	29/ 13	29/ 12	27/ 11	26/ 10	25/ 9	24/ 8	23/ 7	22/ 6	21/ 5	20/ 4	19/ 3	18/ 2	17/ 1	16/ 0
MsgAddr + 0x00	Reserved															
	Reserved											Parity[4:0]				
MsgAddr + 0x04	MXtd	MDir	Rsvd	Msk[28:16]												
	Msk[15:0]															
MsgAddr + 0x08	Rsvd	Xtd	Dir	ID[28:16]												
	ID[15:0]															
MsgAddr + 0x0C	Reserved															
	Rsvd	MsgLst	Rsvd	UMask	TxIE	RxTE	RmtEn	Rsvd	EOB	Reserved		DLC[3:0]				
MsgAddr + 0x10	Data 3								Data 2							
	Data 1								Data 0							
MsgAddr + 0x14	Data 7								Data 6							
	Data 5								Data 4							

25.3.18.4 Message RAM Representation in Direct Access Mode

When the RDA bit in the TEST register is set while the DCAN module is in test mode (test bit in the CTL register is set), the CPU has direct access to the message RAM. Due to the 32-bit bus structure, the RAM is split into word lines to support this feature. The CPU has access to one word line at a time only.

In RAM direct access mode, the RAM is represented by a continuous memory space within the address frame of the DCAN module, starting at the message RAM base address.

Note: During direct access mode, the message RAM cannot be accessed via the IFx register sets.

Any read or write to the RAM addresses for RamDirectAccess during normal operation mode (TestMode bit or RDA bit not set) will be ignored.

Table 25-12. Message RAM Representation in RAM Direct Access Mode

Bit #	31/ 15	30/ 14	29/ 13	29/ 12	27/ 11	26/ 10	25/ 9	24/ 8	23/ 7	22/ 6	21/ 5	20/ 4	19/ 3	18/ 2	17/ 1	16/ 0
MsgAddr + 0x00	Data 4								Data 5							
	Data 6								Data 7							
MsgAddr + 0x04	Data 0								Data 1							
	Data 2								Data 3							
MsgAddr + 0x08	ID[27:12]															
	ID[11:0]											DLC[3:0]				
	Msk[28:13]															

Table 25-12. Message RAM Representation in RAM Direct Access Mode (continued)

Bit #	31/15	30/14	29/13	29/12	27/11	26/10	25/9	24/8	23/7	22/6	21/5	20/4	19/3	18/2	17/1	16/0

MsgAddr + 0x10	Reserved															Parity [4]
	MsgLst				Unused				Msg Lst	UMa sk	TxIE	RxT E	Rmt En	EOB	MX td	MDir

NOTE: Writes to unused bits have no effect.

25.3.19 GIO Support

The CAN_RX and CAN_TX pins of the DCAN module can be used as general purpose IO pins, if CAN functionality is not needed. This function is controlled by the CAN TX IO control register (TIOC) and the CAN RX IO control register (RIOC).

25.4 DCAN Registers

25.4.1 DCAN Registers

Table 25-13 lists the memory-mapped registers for the DCAN. All register offset addresses not listed in Table 25-13 should be considered as reserved locations and the register contents should not be modified.

Table 25-13. DCAN Registers

Offset	Acronym	Register Name	Section

25.4.1.1 DCAN_CTL Register (offset = 0h) [reset = 1401h]

DCAN_CTL is shown in Figure 25-19 and described in Table 25-14.

The Bus-Off recovery sequence (refer to CAN specification) cannot be shortened by setting or resetting Init bit. If the module goes Bus-Off, it will automatically set the Init bit and stop all bus activities. When the Init bit is cleared by the application again, the module will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operation. At the end of the bus-off recovery sequence, the error counters will be reset. After the Init bit is reset, each time when a sequence of 11 recessive bits is monitored, a Bit0 error code is written to the error and status register, enabling the CPU to check whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

Table 25-14. DCAN_CTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-26	RESERVED	R	0h	
25	WUBA	R/W	0h	Automatic wake up on bus activity when in local power-down mode. Note: The CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power down and automatic wake-up mode, will be lost. 0h (R/W) = No detection of a dominant CAN bus level while in local power-down mode. 1h (R/W) = Detection of a dominant CAN bus level while in local power-down mode is enabled. On occurrence of a dominant CAN bus level, the wake up sequence is started.
24	PDR	R/W	0h	Request for local low power-down mode 0h (R/W) = No application request for local low power-down mode. If the application has cleared this bit while DCAN in local power-down mode, also the Init bit has to be cleared. 1h (R/W) = Local power-down mode has been requested by application. The DCAN will acknowledge the local power-down mode by setting bit PDA in the error and status register. The local clocks will be turned off by DCAN internal logic.
23-21	RESERVED	R	0h	
20	DE3	R/W	0h	Enable DMA request line for IF3. Note: A pending DMA request for IF3 remains active until first access to one of the IF3 registers. 0h (R/W) = Disabled 1h (R/W) = Enabled
19	DE2	R/W	0h	Enable DMA request line for IF2. Note: A pending DMA request for IF2 remains active until first access to one of the IF2 registers. 0h (R/W) = Disabled 1h (R/W) = Enabled

Table 25-14. DCAN_CTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18	DE1	R/W	0h	Enable DMA request line for IF1. Note: A pending DMA request for IF1 remains active until first access to one of the IF1 registers. 0h (R/W) = Disabled 1h (R/W) = Enabled
17	IE1	R/W	0h	Interrupt line 1 enable 0h (R/W) = Disabled - Module interrupt DCAN1INT is always low. 1h (R/W) = Enabled - interrupts will assert line DCAN1INT to one; line remains active until pending interrupts are processed.
16	INITDBG	R	0h	Internal init state while debug access 0h (R/W) = Not in debug mode, or debug mode requested but not entered. 1h (R/W) = Debug mode requested and internally entered; the DCAN is ready for debug accesses.
15	SWR	R/WP	0h	SW reset enable. Note: To execute software reset, the following procedure is necessary: (a) Set Init bit to shut down CAN communication and (b) Set SWR bit additionally to Init bit. 0h (R/W) = Normal Operation 1h (R/W) = Module is forced to reset state. This bit will automatically get cleared after execution of SW reset after one OCP clock cycle.
14	RESERVED	R	0h	
13-10	PMD	R/W	5h	Parity on/off. 5 = Parity function disabled. Others = Parity function enabled.
9	ABO	R/W	0h	Auto-Bus-On enable 0h (R/W) = The Auto-Bus-On feature is disabled 1h (R/W) = The Auto-Bus-On feature is enabled
8	IDS	R/W	0h	Interruption debug support enable 0h (R/W) = When Debug/Suspend mode is requested, DCAN will wait for a started transmission or reception to be completed before entering Debug/Suspend mode 1h (R/W) = When Debug/Suspend mode is requested, DCAN will interrupt any transmission or reception, and enter Debug/Suspend mode immediately.
7	TEST	R/W	0h	Test mode enable 0h (R/W) = Normal Operation 1h (R/W) = Test Mode
6	CCE	R/W	0h	Configuration change enable 0h (R/W) = The CPU has no write access to the configuration registers. 1h (R/W) = The CPU has write access to the configuration registers (when Init bit is set).
5	DAR	R/W	0h	Disable automatic retransmission 0h (R/W) = Automatic retransmission of not successful messages enabled. 1h (R/W) = Automatic retransmission disabled.
4	RESERVED	R	0h	
3	EIE	R/W	0h	Error interrupt enable 0h (R/W) = Disabled - PER, BOff and EWarn bits can not generate an interrupt. 1h (R/W) = Enabled - PER, BOff and EWarn bits can generate an interrupt at DCAN0INT line and affect the interrupt register.

Table 25-14. DCAN_CTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	SIE	R/W	0h	Status change interrupt enable 0h (R/W) = Disabled - WakeUpPnd, RxOk, TxOk and LEC bits can not generate an interrupt. 1h (R/W) = Enabled - WakeUpPnd, RxOk, TxOk and LEC can generate an interrupt at DCAN0INT line and affect the interrupt register.
1	IE0	R/W	0h	Interrupt line 0 enable 0h (R/W) = Disabled - Module interrupt DCAN0INT is always low. 1h (R/W) = Enabled - interrupts will assert line DCAN0INT to one; line remains active until pending interrupts are processed.
0	INIT	R/W	1h	Initialization 0h (R/W) = Normal operation 1h (R/W) = Initialization mode is entered

25.4.1.2 DCAN_ES Register (offset = 4h) [reset = 6Fh]

DCAN_ES is shown in Figure 25-20 and described in Table 25-15.

Interrupts are generated by bits PER, BOff and EWarn (if EIE bit in CAN control register is set) and by bits WakeUpPnd, RxOk, TxOk, and LEC (if SIE bit in CAN control register is set). A change of bit EPass will not generate an interrupt. Reading the error and status register clears the WakeUpPnd, PER, RxOk and TxOk bits and set the LEC to value '7.' Additionally, the status interrupt value (0x8000) in the interrupt register will be replaced by the next lower priority interrupt value. The EOI for all other interrupts (DCANINT0 and DCANINT1) are automatically handled by hardware. For debug support, the auto clear functionality of error and status register (clear of status flags by read) is disabled when in debug/suspend mode.

Table 25-15. DCAN_ES Register Field Descriptions

Bit	Field	Type	Reset	Description
31-11	RESERVED	R	0h	
10	PDA	R	0h	Local power-down mode acknowledge 0h (R/W) = DCAN is not in local power-down mode. 1h (R/W) = Application request for setting DCAN to local power-down mode was successful. DCAN is in local power-down mode.
9	WAKEUP_PND		0h	Wake up pending. This bit can be used by the CPU to identify the DCAN as the source to wake up the system. This bit will be reset if error and status register is read. 0h (R/W) = No Wake Up is requested by DCAN. 1h (R/W) = DCAN has initiated a wake up of the system due to dominant CAN bus while module power down.
8	PER		0h	Parity error detected. This bit will be reset if error and status register is read. 0h (R/W) = No parity error has been detected since last read access. 1h (R/W) = The parity check mechanism has detected a parity error in the Message RAM.
7	BOFF	R	0h	Bus-Off state 0h (R/W) = The CAN module is not bus-off state. 1h (R/W) = The CAN module is in bus-off state.
6	EWARN	R	1h	Warning state 0h (R/W) = Both error counters are below the error warning limit of 96. 1h (R/W) = At least one of the error counters has reached the error warning limit of 96.

Table 25-15. DCAN_ES Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	EPASS	R	1h	Error passive state 0h (R/W) = On CAN Bus error, the DCAN could send active error frames. 1h (R/W) = The CAN core is in the error passive state as defined in the CAN Specification.
4	RXOK		0h	Received a message successfully. This bit will be reset if error and status register is read. 0h (R/W) = No message has been successfully received since the last time when this bit was read by the CPU. This bit is never reset by DCAN internal events. 1h (R/W) = A message has been successfully received since the last time when this bit was reset by a read access of the CPU (independent of the result of acceptance filtering).
3	TXOK		1h	Transmitted a message successfully. This bit will be reset if error and status register is read. 0h (R/W) = No message has been successfully transmitted since the last time when this bit was read by the CPU. This bit is never reset by DCAN internal events. 1h (R/W) = A message has been successfully transmitted (error free and acknowledged by at least one other node) since the last time when this bit was reset by a read access of the CPU.
2-0	LEC		7h	Last error code. The LEC field indicates the type of the last error on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. 0h (R/W) = No error 1h (R/W) = Stuff error. More than five equal bits in a row have been detected in a part of a received message where this is not allowed. 2h (R/W) = Form error. A fixed format part of a received frame has the wrong format. 3h (R/W) = Ack error. The message this CAN core transmitted was not acknowledged by another node. 4h (R/W) = Bit1 error. During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant. 5h (R/W) = Bit0 error. During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (logical value '0'), but the monitored bus level was recessive. During Bus-Off recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus-Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed). 6h (R/W) = CRC error. In a received message, the CRC check sum was incorrect. (CRC received for an incoming message does not match the calculated CRC for the received data). 7h (R/W) = No CAN bus event was detected since the last time the CPU read the error and status register. Any read access to the error and status register re-initializes the LEC to value '7.'

25.4.1.3 DCAN_ERRC Register (offset = 8h) [reset = 0h]

DCAN_ERRC is shown in Figure 25-21 and described in Table 25-16.

Figure 25-21. DCAN_ERRC Register

14-8	REC	R	0h	Receive error counter. Actual state of the receive error counter (values from 0 to 255).
7-0	TEC	R	0h	Transmit error counter. Actual state of the transmit error counter (values from 0 to 255).

25.4.1.4 DCAN_BTR Register (offset = Ch) [reset = 2301h]

DCAN_BTR is shown in Figure 25-22 and described in Table 25-17.

This register is only writable if CCE and Init bits in the CAN control register are set. The CAN bit time may be programmed in the range of 8 to 25 time quanta. The CAN time quantum may be programmed in the range of 1 to1024 CAN_CLK periods. With a CAN_CLK of 8 MHz and BRPE = 0x00, the reset value of 0x00002301 configures the DCAN for a bit rate of 500kBit/s.

Table 25-18. DCAN_INT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	RESERVED	R	0h	
23-16	INT1ID_23_16	R	0h	Interrupt 1 Identifier (indicates the message object with the highest pending interrupt). If several interrupts are pending, the CAN interrupt register will point to the pending interrupt with the highest priority. The DCAN1INT interrupt line remains active until Int1ID reaches value 0 (the cause of the interrupt is reset) or until IE1 is cleared. A message interrupt is cleared by clearing the message object's IntPnd bit. Among the message interrupts, the message object's interrupt priority decreases with increasing message number. 0x 00: No interrupt is pending. 0x 01-0x 80: Number of message object which caused the interrupt. 0xFF: Unused.
15-0	INT0ID_15_0	R	0h	Interrupt Identifier (the number here indicates the source of the interrupt). If several interrupts are pending, the CAN interrupt register will point to the pending interrupt with the highest priority. The DCAN0INT interrupt line remains active until Int0ID reaches value 0 (the cause of the interrupt is reset) or until IE0 is cleared. The Status interrupt has the highest priority. Among the message interrupts, the message object's interrupt priority decreases with increasing message number. 0x 0000: No interrupt is pending. 0x 0001-0x 0080: Number of message object which caused the interrupt. 0x 0081-0x7FFF: Unused (values 0081 to 7FFF). 0x 8000: Error and status register value is not 0x07. 0xFFFF: Unused.

25.4.1.6 DCAN_TEST Register (offset = 14h) [reset = 0h]

DCAN_TEST is shown in Figure 25-24 and described in Table 25-19.

For all test modes, the test bit in CAN control register needs to be set to one. If test bit is set, the RDA, EXL, Tx1, Tx0, LBack and Silent bits are writable. Bit Rx monitors the state of pin CAN_RX and therefore is only readable. All test register functions are disabled when test bit is cleared. The test register is only writable if test bit in CAN control register is set. Setting Tx[1:0] other than '00' will disturb message transfer. When the internal loop-back mode is active (bit LBack is set), bit EXL will be ignored.

25.4.1.7 DCAN_PERR Register (offset = 1Ch) [reset = 0h]

DCAN_PERR is shown in Figure 25-25 and described in Table 25-20.

If a parity error is detected, the PER flag will be set in the error and status register. This bit is not reset by the parity check mechanism; it must be reset by reading the error and status register. In addition to the PER flag, the parity error code register will indicate the memory area where the parity error has been detected (message number and word number). If more than one word with a parity error was detected, the highest word number with a parity error will be displayed. After a parity error has been detected, the register will hold the last error code until power is removed.

25.4.1.14 DCAN_NWDAT_X Register (offset = 98h) [reset = 0h]

DCAN_NWDAT_X is shown in Figure 25-32 and described in Table 25-27.

With the new data X register, the CPU can detect if one or more bits in the different new data registers are set. Each register bit represents a group of eight message objects. If at least on of the NewDat bits of these message objects are set, the corresponding bit in the new data X register will be set. Example 1. Bit 0 of the new data X register represents byte 0 of the new data 1 register. If one or more bits in this byte are set, bit 0 of the new data X register will be set.

25.4.1.15 DCAN_NWDAT12 Register (offset = 9Ch) [reset = 0h]

DCAN_NWDAT12 is shown in Figure 25-33 and described in Table 25-28.

These registers hold the NewDat bits of the implemented message objects. By reading out these bits, the CPU can check for new data in the message objects. The NewDat bit of a specific message object can be set/reset by the CPU via the IF1/IF2 interface register sets, or by the message handler after reception of a data frame or after a successful transmission.

25.4.1.31 DCAN_INTMUX56 Register (offset = E0h) [reset = 0h]

DCAN_INTMUX56 is shown in Figure 25-49 and described in Table 25-44.

The IntMux flag determine for each message object, which of the two interrupt lines (DCAN0INT or DCAN1INT) will be asserted when the IntPnd of this message object is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN control register. The IntPnd bit of a specific message object can be set or reset by the CPU via the IF1/IF2 interface register sets, or by message handler after reception or successful transmission of a frame. This will also affect the Int0ID resp Int1ID flags in the interrupt register.

Table 25-44. DCAN_INTMUX56 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	INTMUX	R/W	0h	IntMux[95:64] multiplexes IntPnd value to either DCAN0INT or DCAN1INT interrupt lines. The mapping from the bits to the message objects is as follows. Bit 0 -> last implemented message object. Bit 1 -> message object number 1. Bit 2 -> message object number 2. ... Bit 31 -> message object number 31. 0h (R/W) = DCAN0INT line is active if corresponding IntPnd flag is one. 1h (R/W) = DCAN1INT line is active if corresponding IntPnd flag is one.

25.4.1.32 DCAN_INTMUX78 Register (offset = E4h) [reset = 0h]

DCAN_INTMUX78 is shown in Figure 25-50 and described in Table 25-45.

The IntMux flag determine for each message object, which of the two interrupt lines (DCAN0INT or DCAN1INT) will be asserted when the IntPnd of this message object is set. Both interrupt lines can be globally enabled or disabled by setting or clearing IE0 and IE1 bits in CAN control register. The IntPnd bit of a specific message object can be set or reset by the CPU via the IF1/IF2 interface register sets, or by message handler after reception or successful transmission of a frame. This will also affect the Int0ID resp Int1ID flags in the interrupt register.

Bit	Field	Type	Reset	Description
31-0	INTMUX	R/W	0h	IntMux[127:96] multiplexes IntPnd value to either DCAN0INT or DCAN1INT interrupt lines. The mapping from the bits to the message objects is as follows. Bit 0 -> last implemented message object. Bit 1 -> message object number 1. Bit 2 -> message object number 2. ... Bit 31 -> message object number 31. 0h (R/W) = DCAN0INT line is active if corresponding IntPnd flag is one. 1h (R/W) = DCAN1INT line is active if corresponding IntPnd flag is one.

25.4.1.33 DCAN_IF1CMD Register (offset = 100h) [reset = 0h]

DCAN_IF1CMD is shown in Figure 25-51 and described in Table 25-46.

The IF1 Command Register (IF1CMD) configures and initiates the transfer between the IF1 register sets and the message RAM. It is configurable which portions of the message object should be transferred. A transfer is started when the CPU writes the message number to bits [7:0] of the IF1 command register. With this write operation, the Busy bit is automatically set to '1' to indicate that a transfer is in progress. After 4 to 14 OCP clock cycles, the transfer between the interface register and the message RAM will be completed and the Busy bit is cleared. The maximum number of cycles is needed when the message transfer concurs with a CAN message transmission, acceptance filtering, or message storage. If the CPU writes to both IF1 command registers consecutively (request of a second transfer while first transfer is still in progress), the second transfer will start after the first one has been completed. While Busy bit is one, IF1 register sets are write protected. For debug support, the auto clear functionality of the IF1 command registers (clear of DMAactive flag by r/w) is disabled during Debug/Suspend mode. If an invalid Message Number is written to bits [7:0] of the IF1 command register, the message handler may access an implemented (valid) message object instead.

Table 25-46. DCAN_IF1CMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	CTRL		0h	Access control bits. If the TxRqst/NewDat bit in this register(Bit [18]) is set, the TxRqst/ NewDat bit in the IF1 message control register will be ignored. 0h (R/W) = Control bits will not be changed 1h (R/W) = Direction = Read: The message control bits will be transferred from the message object addressed by message number (Bits [7:0]) to the IF1 register set. Direction = Write: The message control bits will be transferred from the IF1 register set to the message object addressed by message number (Bits [7:0]).
19	CLRINTPND		0h	Clear interrupt pending bit 0h (R/W) = IntPnd bit will not be changed 1h (R/W) = Direction = Read: Clears IntPnd bit in the message object. Direction = Write: This bit is ignored. Copying of IntPnd flag from IF1 Registers to message RAM can only be controlled by the control flag (Bit [20]).
18	TXRQST_NEWDAT		0h	Access transmission request bit. Note: If a CAN transmission is requested by setting TxRqst/NewDat in this register, the TxRqst/NewDat bits in the message object will be set to one independent of the values in IF1 message control Register. Note: A read access to a message object can be combined with the reset of the control bits IntPnd and NewDat. The values of these bits transferred to the IF1 message control register always reflect the status before resetting them. 0h (R/W) = Direction = Read: NewDat bit will not be changed. Direction = Write: TxRqst/NewDat bit will be handled according to the control bit. 1h (R/W) = Direction = Read: Clears NewDat bit in the message object. Direction = Write: Sets TxRqst/NewDat in message object.
17	DATA_A		0h	Access Data Bytes 0 to 3. 0h (R/W) = Data Bytes 0-3 will not be changed. 1h (R/W) = Direction = Read: The data bytes 0-3 will be transferred from the message object addressed by the Message Number (Bits [7:0]) to the corresponding IF1 register set. Direction = Write: The data bytes 0-3 will be transferred from the IF1 register set to the message object addressed by the Message Number (Bits [7:0]). Note: The duration of the message transfer is independent of the number of bytes to be transferred.
16	DATA_B		0h	Access Data Bytes 4 to 7. 0h (R/W) = Data Bytes 4-7 will not be changed. 1h (R/W) = Direction = Read: The data bytes 4-7 will be transferred from the message object addressed by Message Number (Bits [7:0]) to the corresponding IF1 register set. Direction = Write: The data bytes 4-7 will be transferred from the IF1 register set to the message object addressed by message number (Bits [7:0]). Note: The duration of the message transfer is independent of the number of bytes to be transferred.
15	BUSY		0h	Busy flag. This bit is set to one after the message number has been written to bits 7 to 0. IF1 register set will be write protected. The bit is cleared after read/write action has been finished. 0h (R/W) = No transfer between IF1 register set and message RAM is in progress. 1h (R/W) = Transfer between IF1 register set and message RAM is in progress.

Table 25-46. DCAN_IF1CMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	DMAACTIVE		0h	Activation of DMA feature for subsequent internal IF1 update. Note: Due to the auto reset feature of the DMAactive bit, this bit has to be set for each subsequent DMA cycle separately. 0h (R/W) = DMA request line is independent of IF1 activities. 1h (R/W) = DMA is requested after completed transfer between IF1 register set and message RAM. The DMA request remains active until the first read or write to one of the IF1 registers; an exception is a write to Message Number (Bits [7:0]) when DMAactive is one.
13-8	RESERVED	R	0h	
7-0	MESSAGE_NUMBER		0h	Number of message object in message RAM which is used for data transfer. 0h (R/W) = Invalid message number. 1h (R/W) = Valid message numbers (value 01 to 80). 80h (R/W) = Valid message number. 81h (R/W) = Invalid message numbers (value 81 to FF). FFh (R/W) = Invalid message numbers.

25.4.1.34 DCAN_IF1MSK Register (offset = 104h) [reset = E0000000h]

DCAN_IF1MSK is shown in Figure 25-52 and described in Table 25-47.

The bits of the IF1 mask registers mirror the mask bits of a message object. While Busy bit of IF1 command register is one, IF1 register set is write protected.

Note: The duration of the message transfer is independent of the number of bytes to be transferred.
16	DATA_B		0h	Access Data Bytes 4 to 7. 0h (R/W) = Data Bytes 4-7 will not be changed. 1h (R/W) = Direction = Read: The data bytes 4-7 will be transferred from the message object addressed by Message Number (Bits [7:0]) to the corresponding IF2 register set. Direction = Write: The data bytes 4-7 will be transferred from the IF2 register set to the message object addressed by message number (Bits [7:0]). Note: The duration of the message transfer is independent of the number of bytes to be transferred.
15	BUSY		0h	Busy flag. This bit is set to one after the message number has been written to bits 7 to 0. IF2 register set will be write protected. The bit is cleared after read/write action has been finished. 0h (R/W) = No transfer between IF2 register set and message RAM is in progress. 1h (R/W) = Transfer between IF2 register set and message RAM is in progress.

Table 25-52. DCAN_IF2CMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
14	DMAACTIVE		0h	Activation of DMA feature for subsequent internal IF2 update. Note: Due to the auto reset feature of the DMAactive bit, this bit has to be set for each subsequent DMA cycle separately. 0h (R/W) = DMA request line is independent of IF2 activities. 1h (R/W) = DMA is requested after completed transfer between IF2 register set and message RAM. The DMA request remains active until the first read or write to one of the IF2 registers; an exception is a write to Message Number (Bits [7:0]) when DMAactive is one.
13-8	RESERVED	R	0h	
7-0	MESSAGE_NUMBER		0h	Number of message object in message RAM which is used for data transfer. 0h (R/W) = Invalid message number. 1h (R/W) = Valid message numbers (values 01 to 80). 80h (R/W) = Valid message number. 81h (R/W) = Invalid message numbers (values 81 to FF). FFh (R/W) = Invalid message number.

25.4.1.40 DCAN_IF2MSK Register (offset = 124h) [reset = E0000000h]

DCAN_IF2MSK is shown in Figure 25-58 and described in Table 25-53.

The bits of the IF2 mask registers mirror the mask bits of a message object. While Busy bit of IF2 command register is one, IF2 register set is write protected.

Table 25-55. DCAN_IF2MCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15	NEWDAT		0h	New data 0h (R/W) = No new data has been written into the data portion of this message object by the message handler since the last time when this flag was cleared by the CPU. 1h (R/W) = The message handler or the CPU has written new data into the data portion of this message object.
14	MSGLST		0h	Message lost (only valid for message objects with direction = receive) 0h (R/W) = No message lost since the last time when this bit was reset by the CPU. 1h (R/W) = The message handler stored a new message into this object when NewDat was still set, so the previous message has been overwritten.
13	INTPND		0h	Interrupt pending 0h (R/W) = This message object is not the source of an interrupt. 1h (R/W) = This message object is the source of an interrupt. The Interrupt Identifier in the interrupt register will point to this message object if there is no other interrupt source with higher priority.
12	UMASK		0h	Use acceptance mask. If the UMask bit is set to one, the message object's mask bits have to be programmed during initialization of the message object before MsgVal is set to one. 0h (R/W) = Mask ignored 1h (R/W) = Use mask (Msk[28:0], MXtd, and MDir) for acceptance filtering
11	TXIE		0h	Transmit interrupt enable 0h (R/W) = IntPnd will not be triggered after the successful transmission of a frame. 1h (R/W) = IntPnd will be triggered after the successful transmission of a frame.

Table 25-55. DCAN_IF2MCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10	RXIE		0h	Receive interrupt enable 0h (R/W) = IntPnd will not be triggered after the successful reception of a frame. 1h (R/W) = IntPnd will be triggered after the successful reception of a frame.
9	RMTEN		0h	Remote enable 0h (R/W) = At the reception of a remote frame, TxRqst is not changed. 1h (R/W) = At the reception of a remote frame, TxRqst is set.
8	TXRQST		0h	Transmit request 0h (R/W) = This message object is not waiting for a transmission. 1h (R/W) = The transmission of this message object is requested and is not yet done.
7	EOB		0h	Data frame has 0 to 8 data bits. Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one. 0h (R/W) = Data frame has 8 data bytes. 1h (R/W) = Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.
6-4	RESERVED	R	0h	
3-0	DLC		0h	Data length code. Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message. 0x 0-0x 8: Data frame has 0-8 data bytes. 0x 9-0x 15: Data frame has 8 data bytes.

25.4.1.43 DCAN_IF2DATA Register (offset = 130h) [reset = 0h]

DCAN_IF2DATA is shown in Figure 25-61 and described in Table 25-56.

The data bytes of CAN messages are stored in the IF2 registers in the following order: (1) In a CAN data frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. (2) In CAN's serial bit stream, the MSB of each byte will be transmitted first.

Figure 25-61. DCAN_IF2DATA Register

25.4.1.45 DCAN_IF3OBS Register (offset = 140h) [reset = 0h]

DCAN_IF3OBS is shown in Figure 25-63 and described in Table 25-58.

The IF3 register set can automatically be updated with received message objects without the need to initiate the transfer from message RAM by CPU. The observation flags (Bits [4:0]) in the IF3 observation register are used to determine, which data sections of the IF3 interface register set have to be read in order to complete a DMA read cycle. After all marked data sections are read, the DCAN is enabled to update the IF3 interface register set with new data. Any access order of single bytes or half-words is supported. When using byte or half-word accesses, a data section is marked as completed, if all bytes are read. Note: If IF3 Update Enable is used and no Observation flag is set, the corresponding message objects will be copied to IF3 without activating the DMA request line and without waiting for DMA read accesses. A write access to this register aborts a pending DMA cycle by resetting the DMA line and enables updating of IF3 interface register set with new data. To avoid data inconsistency, the DMA controller should be disabled before reconfiguring IF3 observation register. The status of the current read-cycle can be observed via status flags (Bits [12:8]). If an interrupt line is available for IF3, an interrupt will be generated by IF3Upd flag. See the device-specific data sheet for the availability of this interrupt source. With this interrupt, the observation status bits and the IF3Upd bit could be used by the application to realize the notification about new IF3 content in polling or interrupt mode.

7	EOB	R	0h	Data frame has 0 to 8 data bits. Note: This bit is used to concatenate multiple message objects to build a FIFO Buffer. For single message objects (not belonging to a FIFO Buffer), this bit must always be set to one. 0h (R/W) = Data frame has 8 data bytes. 1h (R/W) = Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message.
6-4	RESERVED	R	0h	
3-0	DLC	R	0h	Data Length Code. Note: The data length code of a message object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the message handler stores a data frame, it will write the DLC to the value given by the received message. 0x 0-0x 8: Data frame has 0-8 data bytes. 0x 9-0x 15: Data frame has 8 data bytes.

25.4.1.49 DCAN_IF3DATA Register (offset = 150h) [reset = 0h]

DCAN_IF3DATA is shown in Figure 25-67 and described in Table 25-62.

The data bytes of CAN messages are stored in the IF3 registers in the following order. In a CAN data frame, Data 0 is the first, and Data 7 is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

25.4.1.51 DCAN_IF3UPD12 Register (offset = 160h) [reset = 0h]

DCAN_IF3UPD12 is shown in Figure 25-69 and described in Table 25-64.

The automatic update functionality of the IF3 register set can be configured for each message object. A message object is enabled for automatic IF3 update, if the dedicated IF3UpdEn flag is set. This means that an active NewDat flag of this message object (e.g due to reception of a CAN frame) will trigger an automatic copy of the whole message object to IF3 register set. IF3 Update enable should not be set for transmit objects.

The value of this bit indicates the value to be output to the CAN_RX pin. Forced to Tx output of the CAN core, if Init bit of CAN control register is reset. 0h (R/W) = The CAN_RX pin is driven to logic low 1h (R/W) = The CAN_RX pin is driven to logic high
0	IN	R	0h	CAN_RX data in. Note: When CAN_RX pin is connected to a CAN transceiver, an external pullup resistor has to be used to ensure that the CAN bus will not be disturbed (for example, while reset of the DCAN module). 0h (R/W) = The CAN_RX pin is at logic low 1h (R/W) = The CAN_RX pin is at logic high

Multichannel Serial Port Interface (McSPI)

This chapter describes the McSPI of the device.

Topic **Page**

26.1 Introduction

This document is intended to provide programmers with a functional presentation of the Master/Slave Multichannel Serial Port Interface (McSPI) module. It also provides a register description and a module configuration example.

McSPI is a general-purpose receive/transmit master/slave controller that can interface with up to four slave external devices or one single external master. It allows a duplex, synchronous, serial communication between a CPU and SPI compliant external devices (Slaves and Masters).

26.1.1 McSPI Features

The general features of the SPI controller are:

- Buffered receive/transmit data register per channel (1 word deep)
- Multiple SPI word access with one channel using a FIFO
- Two DMA requests per channel, one interrupt line
- Single interrupt line, for multiple interrupt source events
- Serial link interface supports:
  - Full duplex / Half duplex
  - Multi-channel master or single channel slave operations
  - Programmable 1-32 bit transmit/receive shift operations.
  - Wide selection of SPI word lengths continuous from 4 to 32 bits
- Up to four SPI channels
- SPI word Transmit / Receive slot assignment based on round robin arbitration
- SPI configuration per channel (clock definition, enable polarity and word width)
- Clock generation supports:
  - Programmable master clock generation (operating from fixed 48-MHz functional clock input)
  - Selectable clock phase and clock polarity per chip select.

26.1.2 Unsupported McSPI Features

This device supports only two chip selects per module. Module wakeup during slave mode operation is not supported, as noted in *McSPI Clock and Reset Management*.

Table 26-1. Unsupported McSPI Features

Feature	Reason
Slave mode wakeup	SWAKEUP not connected
Retention during power down	Module not synthesized with retention enabled
McSPI3-4	
Chip selects 2-3	Not pinned out

26.2 Integration

This device includes five instantiations of McSPI: SPI0–SPI4. The McSPI module is a general-purpose receive/transmit master/slave controller that can interface with either up to four slave external devices or one single external master. Figure 26-1 shows the example of a system with multiple external slave SPI compatible devices and Figure 26-2 shows the example of a system with an external master.

Figure 26-1. SPI Master Application

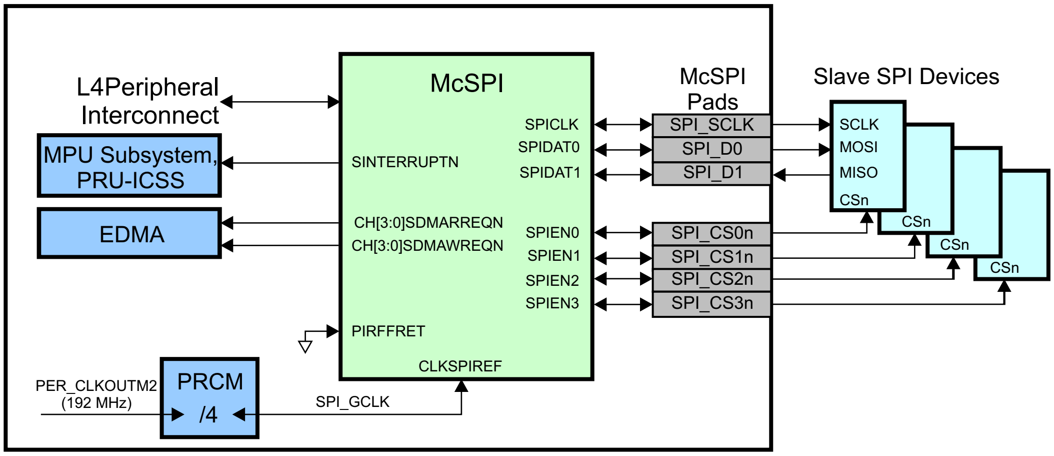

Figure 26-2. SPI Slave Application

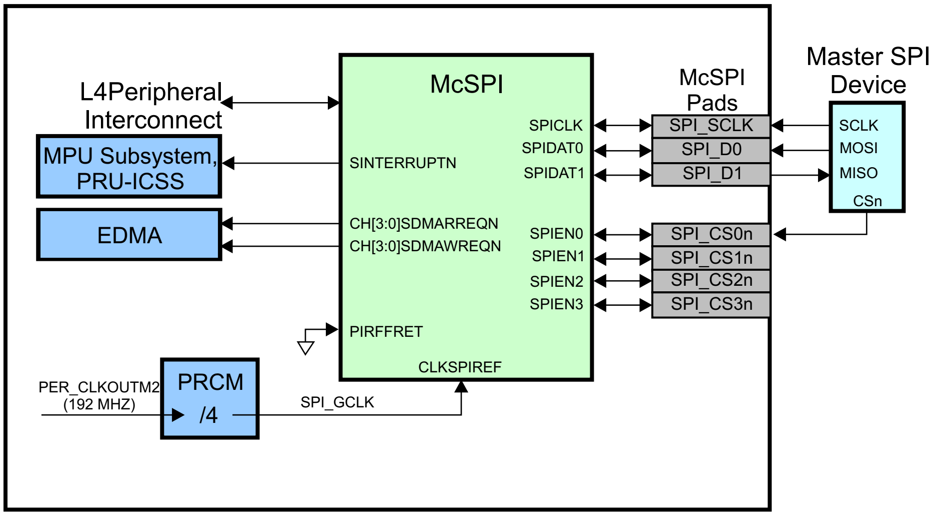


26.2.1 McSPI Connectivity Attributes

The general connectivity attributes for the McSPI module are shown in Table 26-2.

Table 26-2. McSPI Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK (Interface/OCP) PD_PER_SPI_GCLK (Func)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt to MPU subsystem and PRU-ICSS (McSPI0INT) 1 interrupt per instance to MPU subsystem only (McSPI[1-4]INT)
DMA Requests	8 DMA requests per McSPI[0-2] instance, 4 DMA requests per McSPI[3-4] instance to EDMA • 1 RX request for CS0 (SPIREVT0) • 1 TX request for CS0 (SPIXEVT0) • 1 RX request for CS1 (SPIREVT1) • 1 TX request for CS1 (SPIXEVT1) • 1 RX request for CS2 (SPIREVT2), McSPI[0-2] only • 1 TX request for CS2 (SPIXEVT2), McSPI[0-2] only • 1 RX request for CS3 (SPIREVT3), McSPI[0-2] only • 1 TX request for CS3 (SPIXEVT3), McSPI[0-2] only
Physical Address	L4 Peripheral slave port

26.2.2 McSPI Clock and Reset Management

The SPI module clocks can be woken up in two manners: by the SPI module itself using the SWAKEUP signal, or directly from an external SPI master device by detecting an active low level on its chip select input pin (CS0n) using a GPIO attached to that device pin. Neither of these methods is supported on the device.

Table 26-3. McSPI Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
CLK Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk From PRCM
CLKSPIREF Functional clock	48 MHz	PER_CLKOUTM2 / 4	pd_per_spi_gclk From PRCM

26.2.3 McSPI Pin List

The McSPI interface pins are summarized in Table 26-4.

Table 26-4. McSPI Pin List

Pin	Type	Description
SPI*x*_SCLK	I/O(1)	SPI serial clock (output when master, input when slave)
SPI*x*_D0	I/O	Can be configured as either input or output (MOSI or MISO)
SPI*x*_D1	I/O	Can be configured as either input or output (MOSI or MISO)

(1) These signals are also used as inputs to re-time or sync data. The associated CONF_<module>_pin_RXACTIVE bit for these signals must be set to 1 to enable the inputs back to the module. It is also recommended to place a 33-ohm resistor in series (close to the processor) on each of these signals to avoid signal reflections.

Table 26-4. McSPI Pin List (continued)

Pin	Type	Description
SPIx_CS0	I/O	SPI chip select 0 output when master, input when slave (active low)
SPIx_CS1	I/O	SPI chip select 1 output when master, input when slave (active low)
SPIx_CS2	I/O	SPI chip select 2 output when master, input when slave (active low)
SPIx_CS3	I/O	SPI chip select 3 output when master, input when slave (active low)

26.3 Functional Description

26.3.1 SPI Transmission

This section describes the transmissions supported by McSPI. The SPI protocol is a synchronous protocol that allows a master device to initiate serial communication with a slave device. Data is exchanged between these devices. A slave select line (SPIEN) can be used to allow selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities. Connected to multiple external devices, McSPI exchanges data with a single SPI device at a time through two main modes:

- Two data pins interface mode. (See Section 26.3.1.1)
- Single data pin interface mode (recommended for half-duplex transmission). (See Section 26.3.1.2)

The flexibility of McSPI allows exchanging data with several formats through programmable parameters described in Section 26.3.1.3.

26.3.1.1 Two Data Pins Interface Mode

The two data pins interface mode, allows a full duplex SPI transmission where data is transmitted (shifted out serially) and received (shifted in serially) simultaneously on separate data lines SPIDAT [0] and SPIDAT [1]. Data leaving the master exits on transmit serial data line also known as MOSI: MasterOutSlaveIn. Data leaving the slave exits on the receive data line also known as MISO: MasterInSlaveOut.

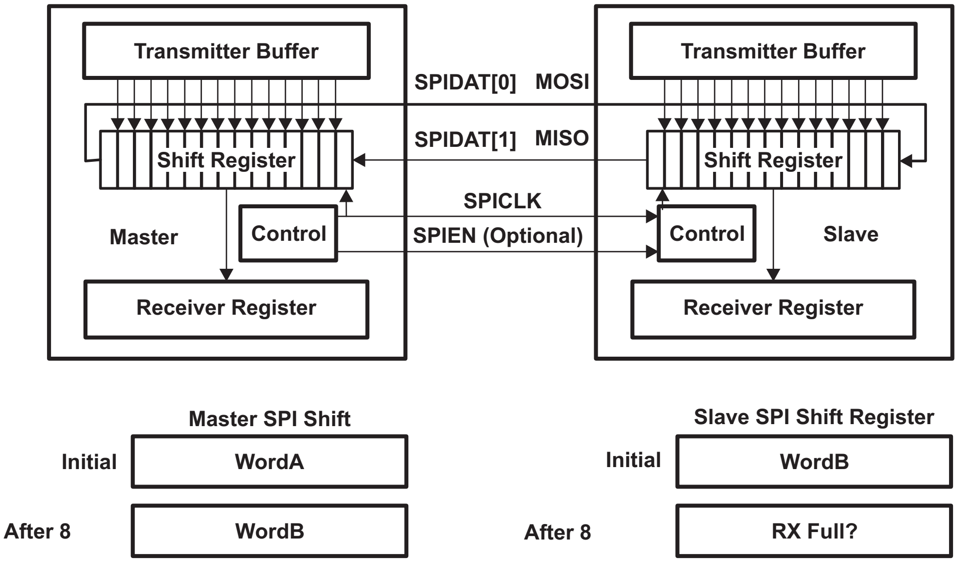
McSPI has a unified SPI port control: SPIDAT [1:0] can be independently configured as receive or transmit lines. The user has the responsibility to program which data line to use and in which direction (receive or transmit), according to the external slave/master connection.

The serial clock (SPICLK) synchronizes shifting and sampling of the information on the two serial data lines (SPIDAT [1:0]). Each time a bit is transferred out from the Master, one bit is transferred in from Slave.

Figure 26-3 shows an example of a full duplex system with a Master device on the left and a Slave device on the right. After 8 cycles of the serial clock SPICLK, the WordA has been transferred from the master to the slave. At the same time, the 8-bit WordB has been transferred from the slave to the master.

When referring to the master device, the control block transmits the clock SPICLK and the enable signal SPIEN (optional, see McSPI_MODULCTRL).

Figure 26-3. SPI Full-Duplex Transmission



26.3.1.2 Single Data Pin Interface Mode

In single data pin interface mode, under software control, a single data line is used to alternatively transmit and receive data (Half duplex transmission).

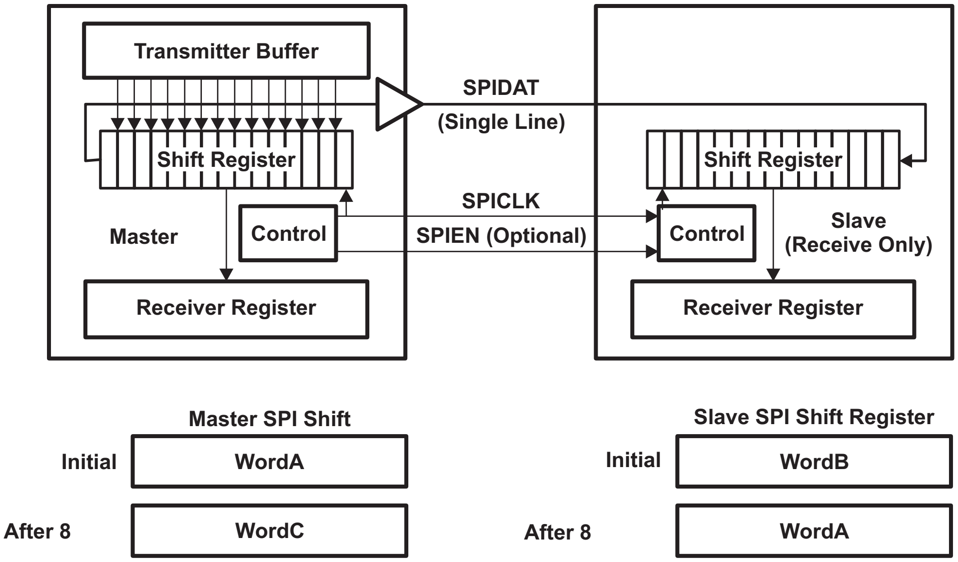
McSPI has a unified SPI port control: SPIDAT [1:0] can be independently configured as receive or transmit lines. The user has the responsibility to program which data line to use and in which direction (receive or transmit), according to the external slave/master connection.

As for a full duplex transmission, the serial clock (SPICLK) synchronizes shifting and sampling of the information on the single serial data line.

26.3.1.2.1 Example With a Receive-Only Slave

Figure 26-4 shows a half duplex system with a Master device on the left and a receive-only Slave device on the right. Each time a bit is transferred out from the Master, one bit is transferred in the Slave. After 8 cycles of the serial clock SPICLK, the 8-bit WordA has been transferred from the master to the slave.

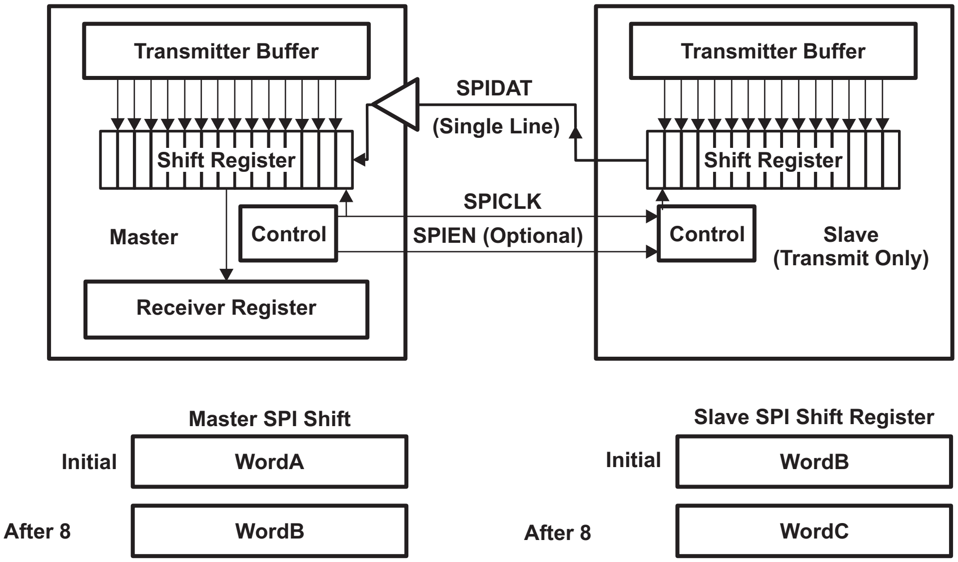
Figure 26-4. SPI Half-Duplex Transmission (Receive-only Slave)



26.3.1.2.2 Example With a Transmit-Only Slave

Figure 26-5 shows a half duplex system with a Master device on the left and a transmit-only Slave device on the right. Each time a bit is transferred out from the Slave, one bit is transferred in the Master. After 8 cycles of the serial clock SPICLK, the 8-bit WordA has been transferred from the slave to the master.

Figure 26-5. SPI Half-Duplex Transmission (Transmit-Only Slave)



26.3.1.3 Transfer Formats

This section describes the transfer formats supported by McSPI.

The flexibility of McSPI allows setting the parameters of the SPI transfer:

- SPI word length
- SPI enable generation programmable
- SPI enable assertion
- SPI enable polarity
- SPI clock frequency
- SPI clock phase
- SPI clock polarity

The consistency between SPI word length, clock phase and clock polarity of the master SPI device and the communicating slave device remains under software responsibility.

26.3.1.3.1 Programmable Word Length

McSPI supports any SPI word from 4 to 32 bits long.

The SPI word length can be changed between transmissions to allow a master device to communicate with peripheral slaves having different requirements.

26.3.1.3.2 Programmable SPI Enable Generation

McSPI is able to generate or not generate SPI enable. If management of chip select is de-asserted, a point-to-point connection is mandatory. Only a single master of a slave device can be connected to the SPI bus.

26.3.1.3.3 Programmable SPI Enable (SPIEN)

The polarity of the SPIEN signals is programmable. SPIEN signals can be active high or low.

The assertion of the SPIEN signals is programmable. SPIEN signals can be manually asserted or automatically asserted.

Two consecutive words for two different slave devices may go along with active SPIEN signals with different polarity.

26.3.1.3.4 Programmable SPI Clock (SPICLK)

The phase and the polarity of the SPI serial clock are programmable when McSPI is a SPI master device or a SPI slave device. The baud rate of the SPI serial clock is programmable when McSPI is a SPI master.

When McSPI is operating as a slave, the serial clock SPICLK is an input from the master.

26.3.1.3.5 Bit Rate

In Master Mode, an internal reference clock CLKSPIREF is used as an input of a programmable divider to generate bit rate of the serial clock SPICLK. Granularity of this clock divider can be changed.

26.3.1.3.6 Polarity and Phase

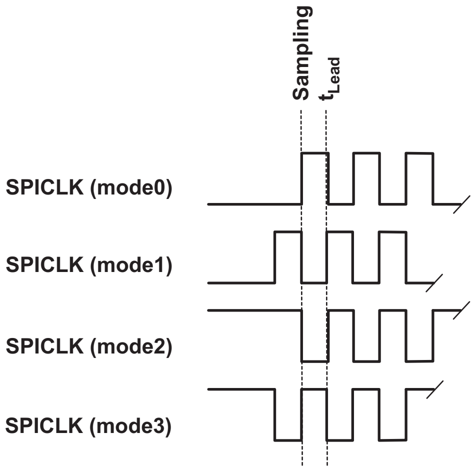
McSPI supports four sub-modes of the SPI format transfer that depend on the polarity (POL) and the phase (PHA) of the SPI serial clock (SPICLK). Table 26-5 and Figure 26-6 show a summary of the four sub-modes. Software selects one of four combinations of serial clock phase and polarity.

Two consecutive SPI words for two different slave devices may go along with active SPICLK signal with different phase and polarity.

Table 26-5. Phase and Polarity Combinations

Polarity (POL)	Phase (PHA)	SPI Mode	Comments
0	0	mode0	SPICLK active high and sampling occurs on the rising edge.
0	1	mode1	SPICLK active high and sampling occurs on the falling edge.
1	0	mode2	SPICLK active low and sampling occurs on the falling edge.
1	1	mode3	SPICLK active low and sampling occurs on the rising edge.

Figure 26-6. Phase and Polarity Combinations



26.3.1.3.7 Transfer Format With PHA = 0

This section describes the concept of a SPI transmission with the SPI mode0 and the SPI mode2.

In the transfer format with PHA = 0, SPIEN is activated a half cycle of SPICLK ahead of the first SPICLK edge.

In both master and slave modes, McSPI drives the data lines at the time of SPIEN is asserted.

Each data frame is transmitted starting with the MSB. At the extremity of both SPI data lines, the first bit of SPI word is valid a half-cycle of SPICLK after the SPIEN assertion.

Therefore, the first edge of the SPICLK line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

On the next SPICLK edge, the received data bit is shifted into the shift register, and a new data bit is transmitted on the serial data line.

This process continues for a total of pulses on the SPICLK line defined by the SPI word length programmed in the master device, with data being latched on odd numbered edges and shifted on even numbered edges.

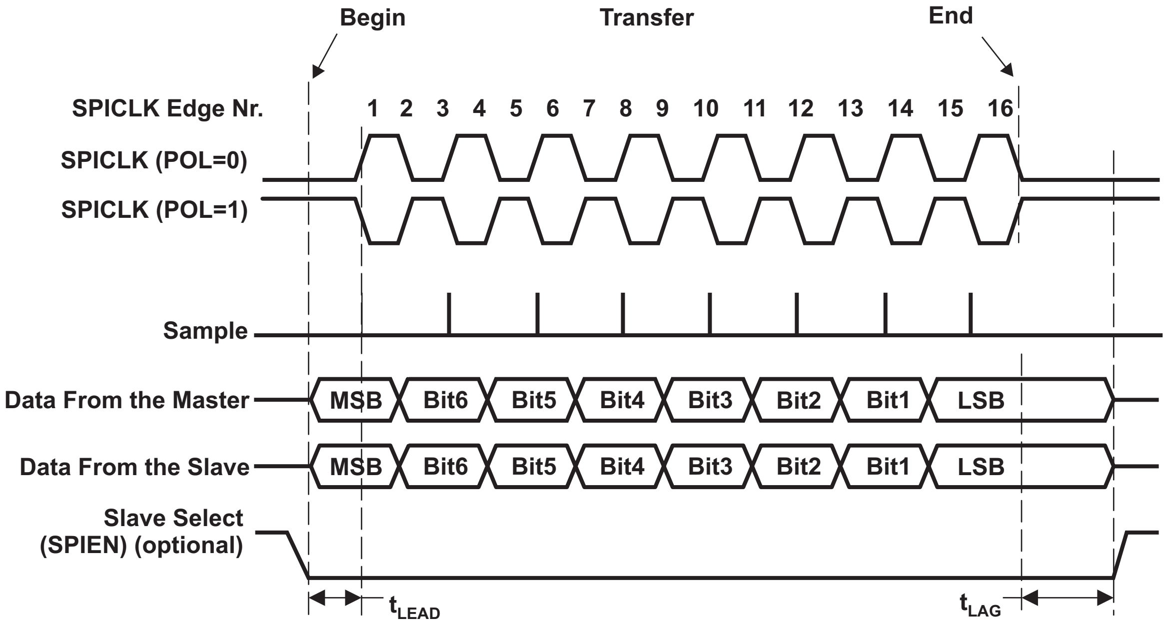
Figure 26-7 is a timing diagram of a SPI transfer for the SPI mode0 and the SPI mode2, when McSPI is master or slave, with the frequency of SPICLK equals to the frequency of CLKSPIREF. It should not be used as a replacement for SPI timing information and requirements detailed in the data manual.

When McSPI is in slave mode, if the SPIEN line is not de-asserted between successive transmissions then the content of the Transmitter register is not transmitted, instead the last received SPI word is transmitted.

In master mode, the SPIEN line must be negated and reasserted between each successive SPI word. This is because the slave select pin freezes the data in its shift register and does not allow it to be altered if PHA bit equals 0.

In 3-pin mode without using the SPIEN signal, the controller provides the same waveform but with SPIEN forced to low state. In slave mode, SPIEN is useless.

Figure 26-7. Full Duplex Single Transfer Format with PHA = 0



26.3.1.3.8 Transfer Format With PHA = 1

This section describes SPI full duplex transmission with the SPI mode1 and the SPI mode3.

In the transfer format with PHA = 1, SPIEN is activated a delay (t_{Lead}) ahead of the first SPICLK edge.

In both master and slave modes, McSPI drives the data lines on the first SPICLK edge.

Each data frame is transmitted starting with the MSB. At the extremity of both SPI data lines, the first bit of SPI word is valid on the next SPICLK edge, a half-cycle later of SPICLK. It is the sampling edge for both the master and slave.

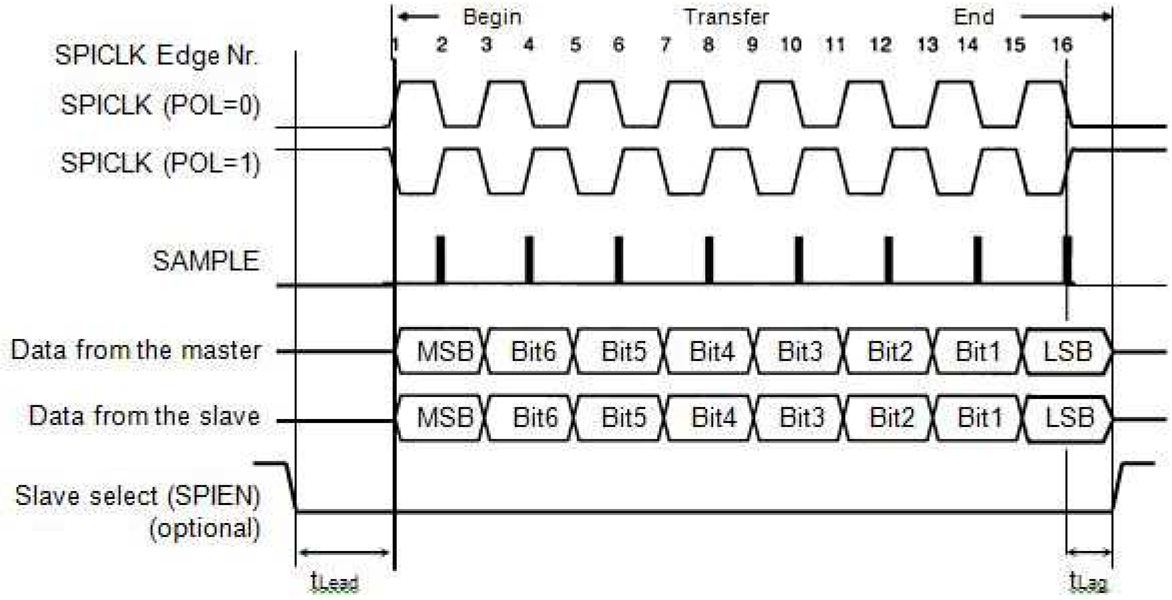
When the third edge occurs, the received data bit is shifted into the shift register. The next data bit of the master is provided to the serial input pin of the slave.

This process continues for a total of pulses on the SPICLK line defined by the word length programmed in the master device, with data being latched on even numbered edges and shifted on odd numbered edges.

Figure 26-8 is a timing diagram of a SPI transfer for the SPI mode1 and the SPI mode3, when McSPI is master or slave, with the frequency of SPICLK equals to the frequency of CLKSPIREF. It should not be used as a replacement for SPI timing information and requirements detailed in the data manual.

The SPIEN line may remain active between successive transfers. In 3-pin mode without using the SPIEN signal, the controller provides the same waveform but with SPIEN forced to low state. In slave mode SPIEN is useless.

Figure 26-8. Full Duplex Single Transfer Format With PHA = 1



26.3.2 Master Mode

McSPI is in master mode when the bit MS of the register MCSPI_MODULCTRL is cleared.

In master mode McSPI supports multi-channel communication with up to 4 independent SPI communication channel contexts. McSPI initiates a data transfer on the data lines (SPIDAT [1:0]) and generates clock (SPICLK) and control signals (SPIEN) to a single SPI slave device at a time.

26.3.2.1 Dedicated Resources Per Channel

In the following sections, the letter “i” indicates the channel number that can be 0, 1, 2 or 3. Each channel has the following dedicated resources:

- Its own channel enable, programmable with the bit EN of the register MCSPI_CH(i)CTRL. Disabling the channel, outside data word transmission, remains under user responsibility.
- Its own transmitter register MCSPI_TX on top of the common shift register. If the transmitter register is empty, the status bit TXS of the register MCSPI_CH(i)STAT is set.
- Its own receiver register MCSPI_RX on top of the common shift register. If the receiver register is full, the status bit RXS of the register MCSPI_CH(i)STAT is set.
- A fixed SPI ENABLE line allocation (SPIEN[i] port for channel "i"), SPI enable management is optional.
- Its own communication configuration with the following parameters via the register MCSPI_CH(i)CONF
  - Transmit/Receive modes, programmable with the bit TRM.
  - Interface mode (Two data pins or Single data pin) and data pins assignment, both programmable with the bits IS and DPE.
  - SPI word length, programmable with the bits WL.
  - SPIEN polarity, programmable with the bit EPOL.
  - SPIEN kept active between words, programmable with the bit FORCE.
  - Turbo mode, programmable with the bit TURBO.
  - SPICLK frequency, programmable with the bit CLKD, the granularity of clock division can be changed using CLKG bit, the clock ratio is then concatenated with MCSPI_CH(i)CTRL[EXTCLK] value.
  - SPICLK polarity, programmable with the bit POL.
  - SPICLK phase, programmable with the bit PHA.
  - Start bit polarity, programmable with the bit SBPOL
  - Use a FIFO Buffer or not (see the following note), programmable with FFER and FFEW, depending on transfer mode, (MCSPI_CH(i)CONF[TRM]).
- Two DMA requests events, read and write, to synchronize read/write accesses of the DMA controller with the activity of McSPI. The DMA requests are enabled with the bits DMAR and DMAW.
- Three interrupts events

Note: When more than one channel has an FIFO enable bit field (FFER or FFEW) set, the FIFO will not be used on any channel. Software must ensure that only one enabled channel is configured to use the FIFO buffer.

The transfers will use the latest loaded parameters of the register MCSPI_CH(i)CONF.

The configuration parameters SPIEN polarity, Turbo mode, SPICLK phase and SPICLK polarity can be loaded in the MCSPI_CH(i)CONF register only when the channel is disabled. The user has the responsibility to change the other parameters of the MCSPI_CH(i)CONF register when no transfer occurs on the SPI interface.

26.3.2.2 Interrupt Events in Master Mode

In master mode, the interrupt events related to the transmitter register state are TX_empty and TX_underflow. The interrupt event related to the receiver register state is RX_full.

26.3.2.2.1 TX_empty

The event TX_empty is activated when a channel is enabled and its transmitter register becomes empty (transient event). Enabling channel automatically raises this event, except for the Master receive only mode. (See Section 26.3.2.5). When the FIFO buffer is enabled (MCSPI_CH(i)CONF[FFEW] set to 1), the TX_empty is asserted as soon as there is enough space in the buffer to write a number of bytes defined by MCSPI_XFERLEVEL[AEL].

Transmitter register must be loaded to remove the source of the interrupt and the TX_empty interrupt status bit must be cleared for interrupt line de-assertion (if event enabled as interrupt source) . (See Section 26.3.4).

When FIFO is enabled, no new TX_empty event will be asserted as soon as CPU has not performed the number of writes into the transmitter register defined by MCSPI_XFERLEVEL[AEL]. It is the responsibility of CPU to perform the right number of writes.

26.3.2.2.2 TX_underflow

The event TX_underflow is activated when the channel is enabled and if the transmitter register or FIFO is empty (not updated with new data) at the time of shift register assignment.

The TX_underflow is a harmless warning in master mode.

To avoid having TX_underflow event at the beginning of a transmission, the event TX_underflow is not activated when no data has been loaded into the transmitter register since channel has been enabled.

To avoid having a TX_underflow event, the Transmit Register (MCSPI_TX(i)) should be loaded as infrequently as possible.

TX_underflow interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

Note: When more than one channel has an FIFO enable bit field (FFER or FFEW) set, the FIFO will not be used on any channel. Software must ensure that only one enabled channel is configured to use the FIFO buffer.

26.3.2.2.3 RX_ full

The event RX_full is activated when channel is enabled and receiver register becomes filled (transient event). When FIFO buffer is enabled (MCSPI_CH(i)CONF[FFER] set to 1), the RX_full is asserted when the number of bytes in the buffer equals the level defined by MCSPI_XFERLEVEL[AFL].

Receiver register must be read to remove source of interrupt and RX_full interrupt status bit must be cleared for interrupt line de-assertion (if event enabled as interrupt source).

When the FIFO is enabled, no new RX_FULL event will be asserted once the CPU has read the number of bytes defined by MCSPI_XFERLEVEL[AFL]. It is the responsibility of the CPU to perform the correct number of read operations.

26.3.2.2.4 End of Word Count

The event end of word (EOW) count is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfers defined in the MCSPI_XFERLEVEL[WCNT] register. If the value was programmed to 0000h, the counter is not enabled and this interrupt is not generated.

The EOW count interrupt also indicates that the SPI transfer has halted on the channel using the FIFO buffer.

The EOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

26.3.2.3 Master Transmit and Receive Mode

This mode is programmable per channel (bit TRM of register MCSPI_CH(i)CONF).

The channel access to the shift registers, for transmission/reception, is based on its transmitter and receiver register state and round robin arbitration.

The channel that meets the rules below is included in the round robin list of already active channels scheduled for transmission and/or reception. The arbiter skips the channel that does not meet the rules and search for the next following enabled channel, in rotation.

Rule 1: Only enabled channels (bit EN of the register MCSPI_CH(i)CTRL), can be scheduled for transmission and/or reception.

Rule 2: An enabled channel can be scheduled if its transmitter register is not empty (bit TXS of the register MCSPI_CH(i)STAT) or its FIFO is not empty when the buffer is used for the corresponding channel (bit FFE of the register MCSPI_CH(i)STAT) at the time of shift register assignment. If the transmitter register or FIFO is empty, at the time of shift register assignment, the event TX_underflow is activated and the next enabled channel with new data to transmit is scheduled. (See also transmit only mode).

Rule 3: An enabled channel can be scheduled if its receive register is not full (bit RXS of the register MCSPI_CH(i)STAT)) or its FIFO is not full when the buffer is used for the corresponding channel (bit FFF of the register MCSPI_CH(i)STAT) at the time of shift register assignment. (See also receive only mode). Therefore the receiver register of FIFO cannot be overwritten. The RX_overflow bit, in the MCSPI_IRQSTS register is never set in this mode.

On completion of SPI word transfer (bit EOT of the register MCSPI_CH(i)STAT is set) the updated transmitter register for the next scheduled channel is loaded into the shift register. This bit is meaningless when using the Buffer for this channel. The serialization (transmit and receive) starts according to the channel communication configuration. On serialization completion the received data is transferred to the channel receive register.

The built-in FIFO is available in this mode and if configured in one data direction, transmit or receive, then the FIFO is seen as a unique 64-byte buffer. If configured in both data directions, transmit and receive, then the FIFO is split into two separate 32-byte buffers with their own address space management. In this last case, the definition of AEL and AFL levels is based on 32 bytes and is under CPU responsibility.

26.3.2.4 Master Transmit-Only Mode

This mode eliminates the need for the CPU to read the receiver register (minimizing data movement) when only transmission is meaningful.

The master transmit only mode is programmable per channel (bits TRM of the register MCSPI_CH(i)CONF).

In master transmit only mode, transmission starts after data is loaded into the transmitter register.

Rule 1 and **Rule 2**, defined above, are applicable in this mode.

Rule 3, defined above, is not applicable: In master transmit only mode, the receiver register or FIFO state “full” does not prevent transmission, and the receiver register is always overwritten with the new SPI word. This event in the receiver register is not significant when only transmission is meaningful. So, the RX_overflow bit, in the MCSPI_IRQSTS register is never set in this mode.

The McSPI module automatically disables the RX_full interrupt status. The corresponding interrupt request and DMA Read request are not generated in master transmit only mode.

The status of the serialization completion is given by the bit EOT of the register MCSPI_CH(i)STAT. This bit is meaningless when using the Buffer for this channel.

The built-in FIFO is available in this mode and can be configured with FFEW bit field in the MCSPI_CH(i)CONF register, then the FIFO is seen as a unique 64-byte buffer.

26.3.2.5 Master Receive-Only Mode

This mode eliminates the need for the CPU to refill the transmitter register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (bits TRM of the register MCSPI_CH(i)CONF).

The master receive only mode enables channel scheduling only on empty state of the receiver register.

Rule 1 and **Rule 3**, defined above, are applicable in this mode.

Rule 2, defined above, is not applicable: In master receive only mode, after the first loading of the transmitter register of the enabled channel, the transmitter register state is maintained as full. The content of the transmitter register is always loaded into the shift register, at the time of shift register assignment. So, after the first loading of the transmitter register, the bits TX_empty and TX_underflow, in the MCSPI_IRQSTS register are never set in this mode.

The status of the serialization completion is given by the bit EOT of the register MCSPI_CH(i)STAT. The bit RX_full in the MCSPI_IRQSTS register is set when a received data is loaded from the shift register to the receiver register. This bit is meaningless when using the Buffer for this channel.

The built-in FIFO is available in this mode and can be configured with FFER bit field in the MCSPI_CH(i)CONF register, then the FIFO is seen as a unique 64-byte buffer.

26.3.2.6 Single-Channel Master Mode

When the SPI is configured as a master device with a single enabled channel, the assertion of the SPIM_CSX signal can be controlled in two different ways:

- In 3 pin mode : MCSPI_MODULCTRL[1] PIN34 and MCSPI_MODULCTRL[0] SINGLE bit are set to 1, the controller transmit SPI word as soon as transmit register or FIFO is not empty.
- In 4 pin mode : MCSPI_MODULCTRL[1] PIN34 bit is cleared to 0 and MCSPI_MODULCTRL[0] SINGLE bit is set to 1, SPIEN assertion/deassertion controlled by Software. (See Section 26.3.2.6.1) using the MCSPI_CH(i)CONF[20] FORCE bit.

26.3.2.6.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for completion of the SPI word transfer (bit EOT of the register MCSPI_CH(i)STAT is set) before disabling the current channel and enabling a different channel.
- Disable the current channel first, and then enable the other channel.

26.3.2.6.2 Keep SPIEN Active Mode (Force SPIEN)

Continuous transfers are manually allowed by keeping the SPIEN signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the SPIEN line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the SPIEN active mode is supported when:

- A single channel is used (bit MCSPI_MODULCTRL[Single] is set to 1).
- Transfer parameters of the transfer are loaded in the configuration register (MCSPI_CH(i)CONF) in the appropriate channel.

  The state of the SPIEN signal is programmable.

  - Writing 1 into the bit FORCE of the register MCSPI_CH(i)CONF drives high the SPIEN line when MCSPI_CH(i)CONF[EPOL] is set to zero, and drives it low when MCSPI_CH(i)CONF[EPOL] is set.
  - Writing 0 into the bit FORCE of the register MCSPI_CH(i)CONF drives low the SPIEN line when MCSPI_CH(i)CONF[EPOL] is set to zero, and drives it high when MCSPI_CH(i)CONF[EPOL] is set.
- A single channel is enabled (MCSPI_CH(i)CTRL[En] set to 1) . The first enabled channel activates the SPIEN line.

Once the channel is enabled, the SPIEN signal is activated with the programmed polarity.

As in multi-channel master mode, the start of the transfer depends on the status of the transmitter register, the status of the receiver register and the mode defined by the bits TRM in the configuration register (transmit only, receive only or transmit and receive) of the enabled channel.

The status of the serialization completion of each SPI word is given by the bit EOT of the register MCSPI_CH(i)STAT. The bit RX_full in the MCSPI_IRQSTS register is set when a received data is loaded from the shift register to the receiver register.

A change in the configuration parameters is propagated directly on the SPI interface. If the SPIEN signal is activated the user must insure that the configuration is changed only between SPI words, in order to avoid corrupting the current transfer.

NOTE: The SPIEN polarity, the SPICLK phase and SPICLK polarity must not be modified when the SPIEN signal is activated. The Transmit/Receive mode, programmable with the bit TRM can be modified only when the channel is disabled. The channel can be disabled and enabled while the SPIEN signal is activated.

The delay between SPI words that requires the connected SPI slave device to switch from one configuration (transmit only for instance) to another (receive only for instance) must be handled under software responsibility.

At the end of the last SPI word, the channel must be deactivated (MCSPI_CH(i)CTRL[En] is cleared to 0) and the SPIEN can be forced to its inactive state (MCSPI_CH(i)CONF[Force]).

Figure 26-9 and Figure 26-10 show successive transfers with SPIEN kept active low with a different configuration for each SPI word in respectively single data pin interface mode and two data pins interface mode. The arrows indicate when the channel is disabled before a change in the configuration parameters and enabled again.

Figure 26-9. Continuous Transfers With SPIEN Maintained Active (Single-Data-Pin Interface Mode)

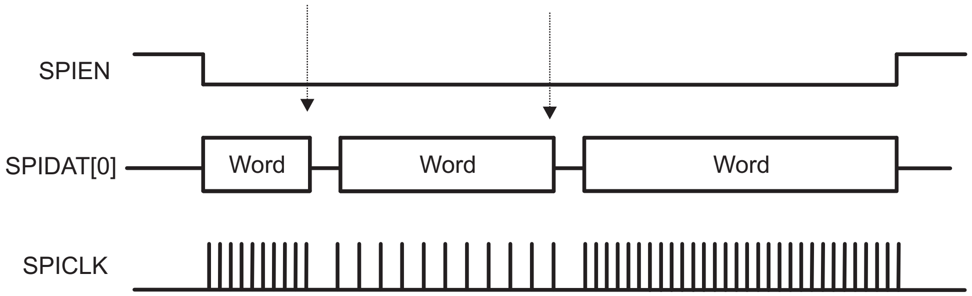


Figure 26-10. Continuous Transfers With SPIEN Maintained Active (Dual-Data-Pin Interface Mode)

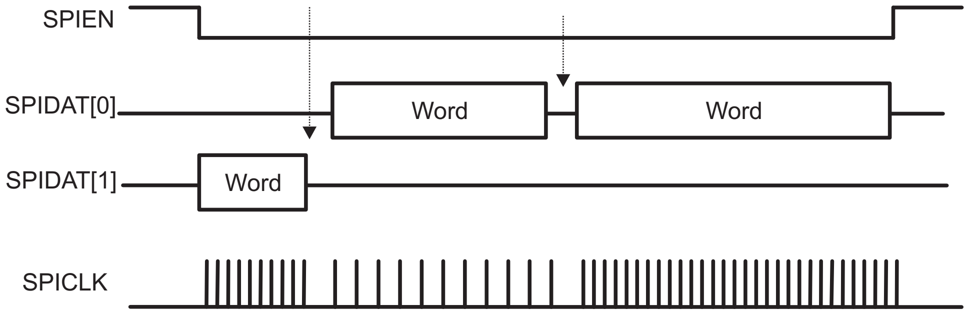


NOTE: The turbo mode is also supported for the Keep SPIEN active mode when the following conditions are met:

- A single channel will be explicitly used (bit MCSPI_MODULCTRL[Single] is set to 1).
- The turbo mode is enabled in the configuration of the channel (bit Turbo of the register MCSPI_CH(i)CONF).

26.3.2.6.3 Turbo Mode

The purpose of the Turbo mode is to improve the throughput of the SPI interface when a single channel is enabled, by allowing transfers until the shift register and the receiver register are full.

This mode is programmable per channel (bit Turbo of the register MCSPI_CH(i)CONF). When several channels are enabled, the bit Turbo of the registers MCSPI_CH(i)CONF has no effect, and the channel access to the shift registers remains as described in Section 26.3.2.3.

In Turbo mode, **Rule 1** and **Rule 2** defined in Section 26.3.2.3 are applicable but Rule 3 is not applicable. An enabled channel can be scheduled if its receive register is full (bit RXS of the register MCSPI_CH(i)STAT) at the time of shift register assignment until the shift register is full.

In Turbo mode, **Rule 1** and **Rule 2** defined in Section 26.3.2.3 are applicable but Rule 3 is not applicable. An enabled channel can be scheduled if its receive register is full (bit RXS of the register MCSPI_CH(i)STAT) at the time of shift register assignment until the shift register is full.

The receiver register cannot be overwritten in Turbo mode. In consequence the RX_overflow bit, in MCSPI_IRQSTS register is never set in this mode.

26.3.2.7 Start Bit Mode

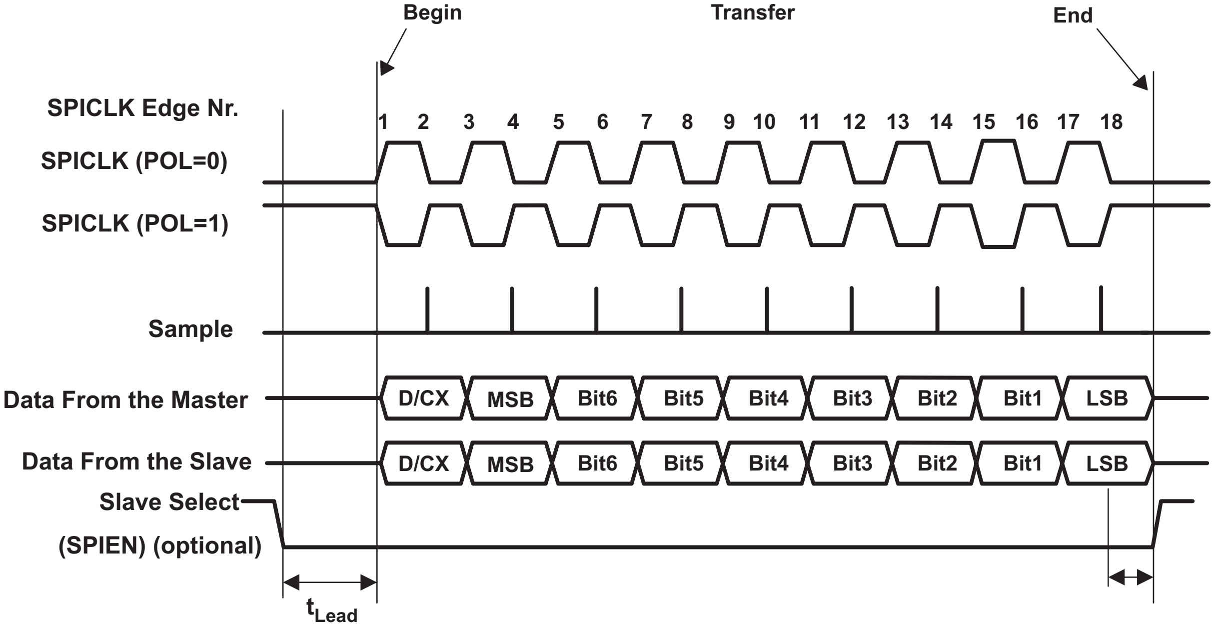
The purpose of the start bit mode is to add an extended bit before the SPI word transmission specified by word length WL. This feature is only available in master mode.

This mode is programmable per channel using the start bit enable (SBE) bit of the register MCSPI_CH(i)CONF).

The polarity of the extended bit is programmable per channel and it indicates whether the next SPI word must be handled as a command when SBPOL is cleared to 0 or as a data or a parameter when SBPOL is set to 1. Moreover start bit polarity SBPOL can be changed dynamically during start bit mode transfer without disabling the channel for reconfiguration, in this case you have the responsibility to configure the SBPOL bit before writing the SPI word to be transmitted in TX register.

The start bit mode could be used at the same time as turbo mode and/or manual chip select mode. In this case only one channel could be used, no round-robin arbitration is possible.

Figure 26-11. Extended SPI Transfer With Start Bit PHA = 1

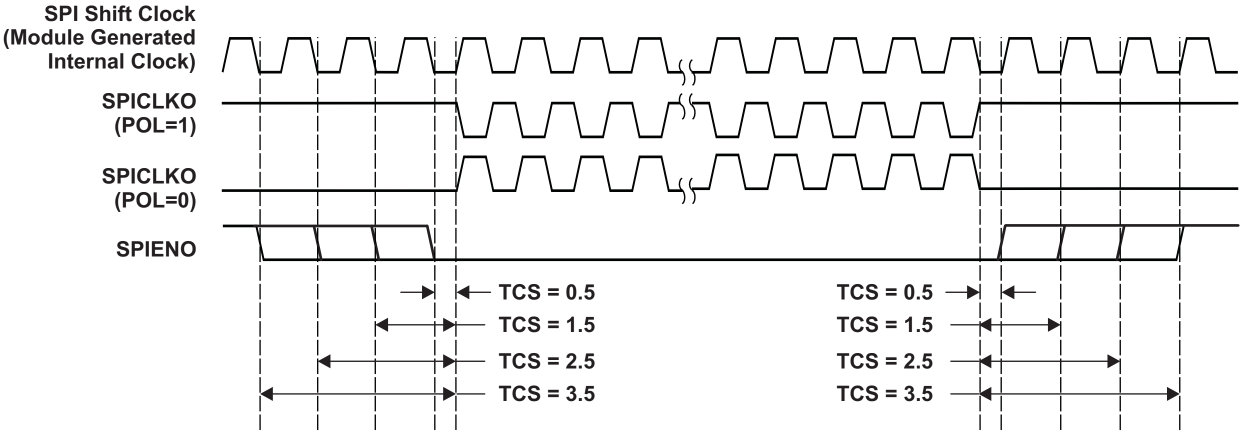


26.3.2.8 Chip-Select Timing Control

The chip select timing control is only available in master mode with automatic chip select generation (FORCE bit field is cleared to 0), to add a programmable delay between chip select assertion and first clock edge or chip select removal and last clock edge. The option is available only in 4 pin mode MCSPI_MODULCTRL[1] PIN34 is cleared to 0.

This mode is programmable per channel (bit TCS of the register MCSPI_CH(i)CONF). Figure 26-12 shows the chip-select SPIEN timing control.

Figure 26-12. Chip-Select SPIEN Timing Controls



NOTE: Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between chip-select assertion and the first clock edge with PHA = 1 or between chip-select removal and the last clock edge with PHA = 0.

With an odd clock divider ratio which occurs when granularity is one clock cycle, that means that MCSPI_CH(i)CONF[CLKG] is set to 1 and MCSPI_CH(i)CONF[CLKD] has an even value, the clock duty cycle is not 50%, then one of the high level or low level duration is selected to be added to TCS delay.

Table 26-6 summarizes all delays between chip select and first (setup) or last (hold) clock edge.

In 3-pin mode this option is useless, the chip select SPIEN is forced to low state.

Table 26-6. Chip Select ↔ Clock Edge Delay Depending on Configuration

Clock Ratio F_{ratio}	Clock Phase PHA	Chip Select ↔ Clock Edge Delay	
		Setup	Hold
1	0	T_ref × (TCS + ½)	T_ref × (TCS + 1)
	1	T_ref × (TCS + 1)	T_ref × (TCS + ½)
Even ≥ 2	x	T_ref × F_{ratio} × (TCS + ½)	T_ref × F_{ratio} × (TCS + ½)
Odd ≥ 3 (only with MCSPI_CH(i)CONF[CLKG] set to 1	0	T_ref × [{F_{ratio} × TCS) + (F_{ratio} + ½)]	T_ref × [{F_{ratio} × TCS) + (F_{ratio} + ½)]
	1	T_ref × [{F_{ratio} × TCS) + (F_{ratio} - ½)]	T_ref × [{F_{ratio} × TCS) + (F_{ratio} - ½)]

T_ref = CLKSPIREF period in ns. F_{ratio} = SPI clock division ratio

The clock divider ratio depends on divider granularity MCSPI_CH(i)CONF[CLKG]:

- MCSPI_CH(i)CONF[CLKG] = 0 : granularity is power of two.
  $F_{ratio} = 2^{MCSPI\_CH(i)CONF[CLKD]}$
- MCSPI_CH(i)CONF[CLKG] = 1 : granularity is one cycle.
  F_{ratio} = MCSPI_CH(i)CTRL[EXTCLK] × MCSPI_CH(i)CONF[CLKD] + 1

26.3.2.9 Clock Ratio Granularity

By default the clock division ratio is defined by the register MCSPI_CH(i)CONF[CLKD] with power of two granularity leading to a clock division in range 1 to 32768, in this case the duty cycle is always 50%. With bit MCSPI_CH(i)CONF[CLKG] the clock division granularity can be changed to one clock cycle, in that case the register MCSPI_CH(i)CTRL[EXTCLK] is concatenated with MCSPI_CH(i)CONF[CLKD] to give a 12-bit width division ratio in range 1 to 4096.

When granularity is one clock cycle (MCSPI_CH(i)CONF[CLKG] set to 1), for odd value of clock ratio the clock duty cycle is kept to 50-50 using falling edge of clock reference CLKSPIREF.

Table 26-7. CLKSPIO High/Low Time Computation

Clock Ratio F_{ratio}	CLKSPIO High Time	CLKSPIO Low Time
1	T_{high}_ref	T_{low}_ref
Even ≥ 2	t_ref × (F_{ratio}/2)	t_ref × (F_{ratio}/2)
Odd ≥ 3	t_ref × (F_{ratio}/2)	t_ref × (F_{ratio}/2)

T_ref = CLKSPIREF period in ns. T_{high}_ref = CLKSPIREF high Time period in ns. T_{low}_ref = CLKSPIREF low Time period in ns. F_{ratio} = SPI clock division ratio

F_{ratio} = MCSPI_CH(i)CTRL[EXTCLK] × MCSPI_CH(i)CONF[CLKD] + 1

For odd ratio value the duty cycle is calculated as below:

Duty_cycle = ½

Granularity examples: With a clock source frequency of 48 MHz:

Table 26-8. Clock Granularity Examples

MCSPI_CH (i)CTRL	MCSPI_CH (i)CONF	MCSPI_CH (i)CONF		MCSPI_CH (i)CONF	MCSPI_CH (i)CONF					
EXTCLK	CLKD	CLKG	F_{ratio}	PHA	POL	Thigh (ns)	Tlow (ns)	Tperiod (ns)	Duty Cycle	Fout (MHz)
X	0	0	1	X	X	10.4	10.4	20.8	50-50	48
X	1	0	2	X	X	20.8	20.8	41.6	50-50	24
X	2	0	4	X	X	41.6	41.6	83.2	50-50	12
X	3	0	8	X	X	83.2	83.2	166.4	50-50	6
0	0	1	1	X	X	10.4	10.4	20.8	50-50	48
0	1	1	2	X	X	20.8	20.8	41.6	50-50	24
0	2	1	3	1	0	31,2	31,2	62.4	50-50	16
0	2	1	3	1	1	31,2	31,2	62.4	50-50	16
0	3	1	4	X	X	41.6	41.6	83.2	50-50	12
5	0	1	81	1	0	842,4	842,4	1684.8	50-50	0.592
5	7	1	88	X	X	915.2	915.2	1830.4	50-50	0.545

26.3.2.10 FIFO Buffer Management

The McSPI controller has a built-in 64-byte buffer in order to unload DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel and is selected by setting MCSPI_CH(i)CONF[FFER] and/or MCSPI_CH(i)CONF[FFEW] to 1.

If several channels are selected and several FIFO enable bit fields set to 1, the controller forces the buffer to be disabled for all channels. It is the responsibility of the driver to enable the buffer for only one channel.

The buffer can be used in the modes defined below:

- Master or Slave mode.
- Transmit only, Receive only or Transmit/Receive mode.
- Single channel or turbo mode, or in normal round robin mode. In round robin mode the buffer is used by only one channel.
- All word length MCSPI_CH(i)CONF[WL] are supported.

Two levels AEL and AFL located in MCSPI_XFERLEVEL register rule the buffer management. The granularity of these levels is one byte, then it is not aligned with SPI word length. It is the responsibility of the driver to set these values as a multiple of SPI word length defined in MCSPI_CH(i)CONF[WL]. The number of byte written in the FIFO depends on word length (see Table 26-9).

Table 26-9. FIFO Writes, Word Length Relationship

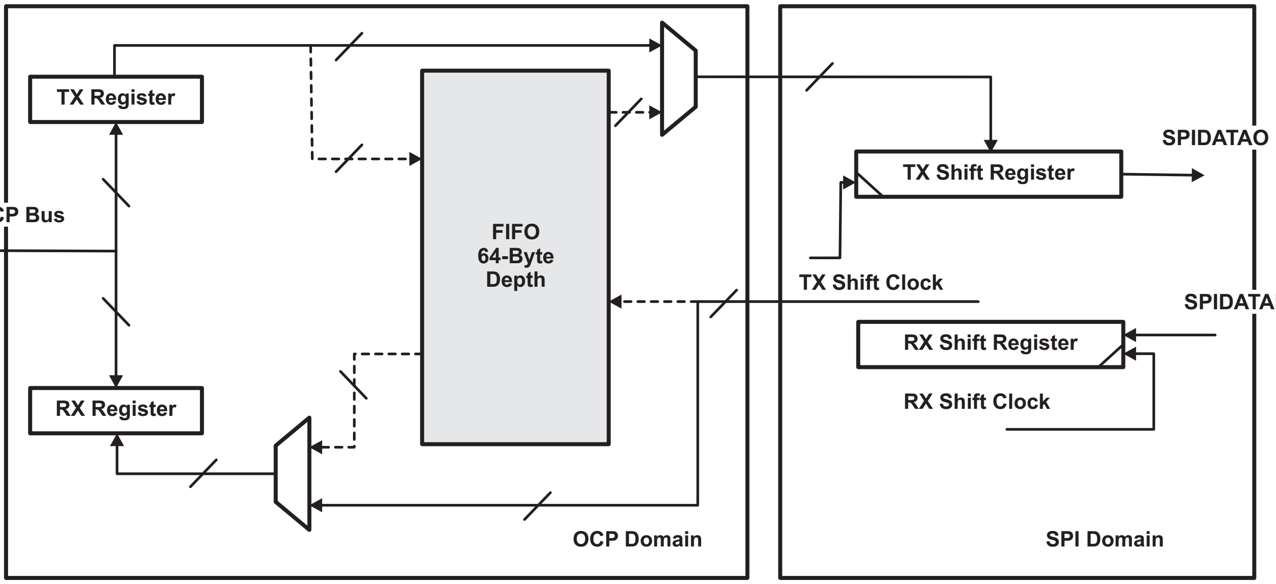
	SPI Word Length WL		
	3 ≤ WL ≤ 7	**8 ≤ WL ≤ 15**	**16 ≤ WL ≤ 31**
Number of byte written in the FIFO	1 byte	2 bytes	4 bytes

26.3.2.10.1 Split FIFO

The FIFO can be split into two part when module is configured in transmit/receive mode MCSPI_CH(i)CONF[TRM] is cleared to 0 and MCSPI_CH(i)CONF[FFER] and MCSPI_CH(i)CONF[FFEW] asserted. Then system can access a 32-byte depth FIFO per direction.

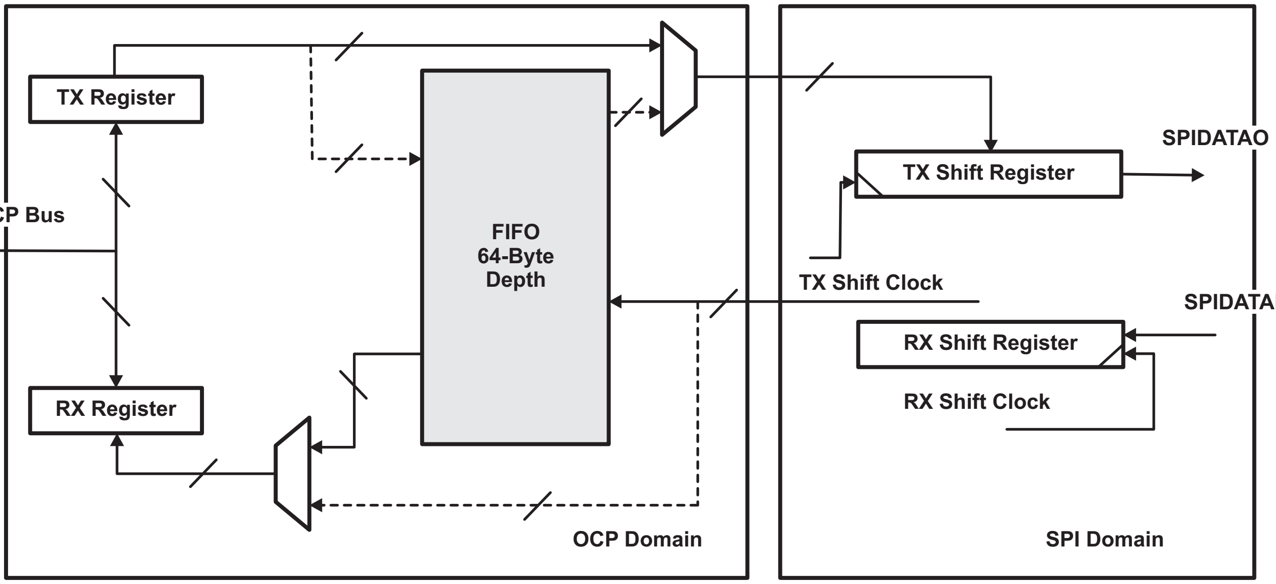
The FIFO buffer pointers are reset when the corresponding channel is enabled or FIFO configuration changes.

Figure 26-13. Transmit/Receive Mode With No FIFO Used



Configuration:
MCSPI_CH(i)CONF[TRM]=0x0 Transmit/receive mode
MCSPI_CH(i)CONF[FFRE]=0x0 FIFO disabled on receive path
MCSPI_CH(i)CONF[FFWE]=0x0 FIFO disabled on transmit path

Figure 26-14. Transmit/Receive Mode With Only Receive FIFO Enabled



Configuration:
MCSPI_CH(i)CONF[TRM]=0x0 Transmit/receive mode

MCSPI_CH(i)CONF[FFWE] not applicable

26.3.2.10.2 Buffer Almost Full

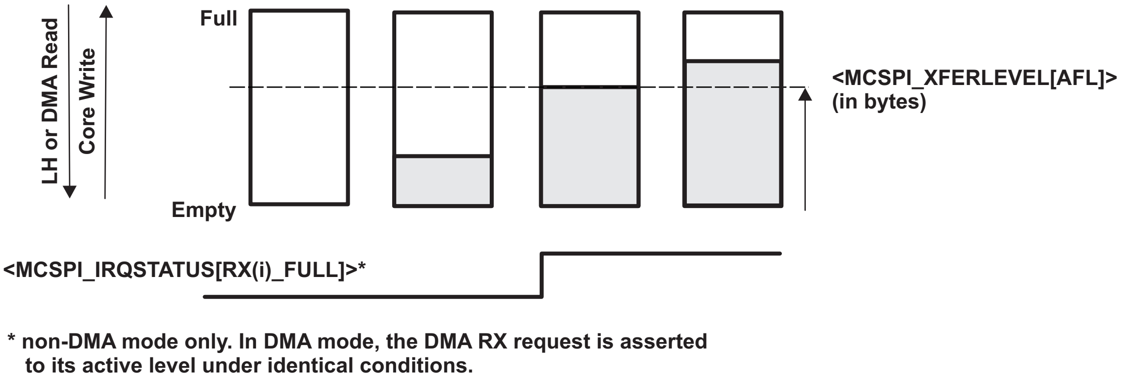
The bit field MCSPI_XFERLEVEL[AFL] is needed when the buffer is used to receive SPI word from a slave (MCSPI_CH(i)CONF[FFER] must be set to 1). It defines the almost full buffer status.

When FIFO pointer reaches this level an interrupt or a DMA request is sent to the CPU to enable system to read AFL+1 bytes from receive register. Be careful AFL+1 must correspond to a multiple value of MCSPI_CH(i)CONF[WL].

When DMA is used, the request is de-asserted after the first receive register read.

No new request will be asserted until the system has performed the correct number of read operations from the buffer.

Figure 26-19. Buffer Almost Full Level (AFL)



.

NOTE: SPI_IRQSTS register bits are not available in DMA mode. In DMA mode, the SPIm_DMA_RX*n* request is asserted on the same conditions as the SPI_IRQSTS RX*n*_FULL flag.

26.3.2.10.3 Buffer Almost Empty

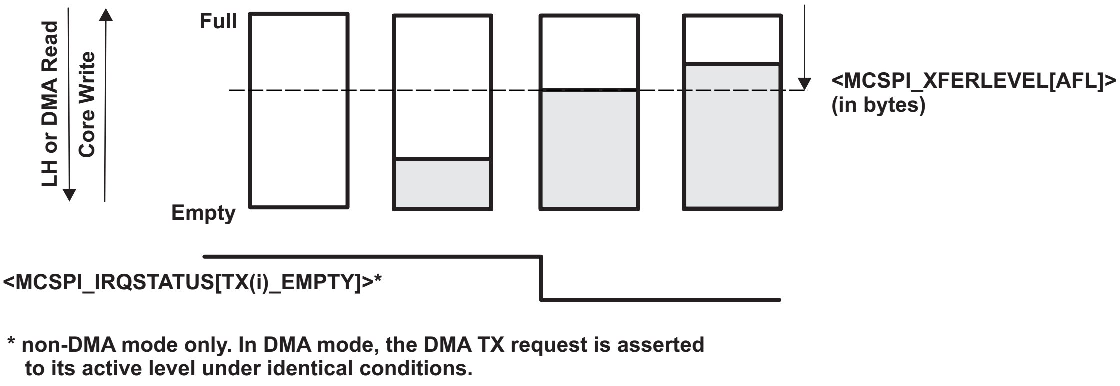
The bitfield MCSPI_XFERLEVEL[AEL] is needed when the buffer is used to transmit SPI word to a slave (MCSPI_CH(i)CONF[FFEW]must be set to 1). It defines the almost empty buffer status.

When FIFO pointer has not reached this level an interrupt or a DMA request is sent to the CPU to enable system to write AEL+1 bytes to transmit register. Be careful AEL+1 must correspond to a multiple value of MCSPI_CH(i)CONF[WL].

When DMA is used, the request is de-asserted after the first transmit register write.

No new request will be asserted until the system has performed the correct number of write operations.

Figure 26-20. Buffer Almost Empty Level (AEL)



.

26.3.2.10.4 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user should configure the MCSPI_XFERLEVEL register, the AEL and AFL levels, and, especially, the WCNT bit field to define the number of SPI word to be transferred using the FIFO. This should be done before enabling the channel.

This counter allows the controller to stop the transfer correctly after a defined number of SPI words have been transferred. If WNCT is cleared to 0, the counter is not used and the user must stop the transfer manually by disabling the channel, in this case the user doesn’t know how many SPI transfers have been done. For receive transfer, software shall poll the corresponding FFE bit field and read the Receive register to empty the FIFO buffer.

When End Of Word count interrupt is generated, the user can disable the channel and poll on MCSPI_CH(i)STAT[FFE] register to know if SPI word is still there in FIFO buffer and read last words.

26.3.2.10.5 Multiple SPI Word Access

The CPU has the ability to perform multiple SPI word access to the receive or transmit registers within a single 32-bit OCP access by setting the bit field MCSPI_MODULCTRL[MOA] to ‘1’ under specific conditions:

- The channel selected has the FIFO enable.
- Only FIFO sense enabled support the kind of access.
- The bit field MCSPI_MODULCTRL[MOA] is set to 1
- Only 32-bit OCP access and data width can be performed to receive or transmit registers, for other kind of access the CPU must de-assert MCSPI_MODULCTRL[MOA] bit fields.
- The Level MCSPI_XFERLEVEL[AEL] and MCSPI_XFERLEVEL[AFL] must be 32-bit aligned , it means that AEL[0] = AEL[1] = 1 or AFL[0] = AFL[1] = 1.
- If MCSPI_XFERLEVEL[WCNT] is used it must be configured according to SPI word length.
- The word length of SPI words allows to perform multiple SPI access, that means that MCSPI_CH(i)CONF[WL] < 16.

Number of SPI word access depending on SPI word length:

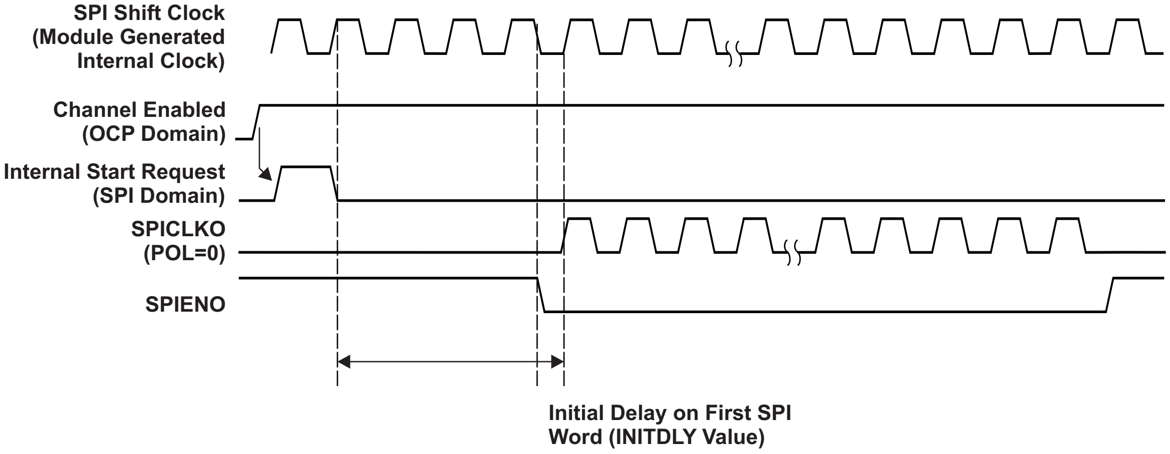
- 3 ≤ WL ≤ 7, SPI word length smaller or equal to byte length, four SPI words accessed per 32-bit OCP read/write. If word count is used (MCSPI_XFERLEVEL[WCNT]), set the bit field to WCNT[0]=WCNT[1]=0.
- 8 ≤ WL ≤ 15, SPI word length greater than byte or equal to 16-bit length, two SPI words accessed per 32-bit OCP read/write. If word count is used (MCSPI_XFERLEVEL[WCNT]), set the bit field to WCNT[0]= 0.
- 16 ≤ WL multiple SPI word access not applicable.

26.3.2.11 First SPI Word Delayed

The McSPI controller has the ability to delay the first SPI word transfer to give time for system to complete some parallel processes or fill the FIFO in order to improve transfer bandwidth. This delay is applied only on first SPI word after SPI channel enabled and first write in Transmit register. It is based on output clock frequency.

This option is meaningful in master mode and single channel mode, MCSPI_MODULCTRL[SINGLE] = 1.

Figure 26-21. Master Single Channel Initial Delay



Few delay values are available: No delay, 4/8/16/32 SPI cycles.

Its accuracy is half cycle in clock bypass mode and depends on clock polarity and phase.

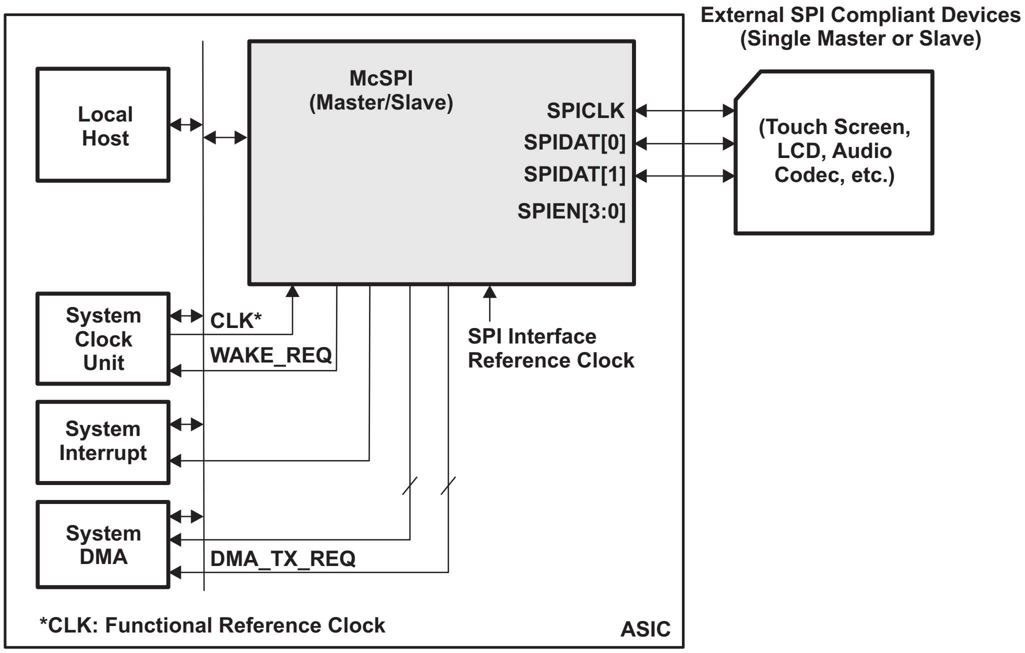
26.3.2.12 3- or 4-Pin Mode

External SPI bus interface can be configured to use a restricted set of pins using the bit field MCSPI_MODULCTRL[PIN34] and depending on targeted application:

- If MCSPI_MODULCTRL[PIN34] is cleared to 0 (default value) the controller is in 4-pin mode using the SPI pins SPICLK, SOMI, SIMO and chip enable CS.
- If MCSPI_MODULCTRL[PIN34] is set to 1 the controller is in 3-pin mode using the SPI pins SPICLK, SOMI and SIMO.

In 3-pin mode it is mandatory to put the controller in single channel master mode (MCSPI_MODULCTRL[SINGLE] asserted) and to connect only one SPI device on the bus.

Figure 26-22. 3-Pin Mode System Overview



In 3-pin mode all options related to chip select management are useless:

- MCSPI_CHxCONF[EPOL]
- MCSPI_CHxCONF[TCS0]
- MCSPI_CHxCONF[FORCE]

The chip select pin SPIEN is forced to ‘0’ in this mode.

26.3.3 Slave Mode

McSPI is in slave mode when the bit MS of the register MCSPI_MODULCTRL is set.

In slave mode, McSPI can be connected to up to 4 external SPI master devices. McSPI handles transactions with a single SPI master device at a time.

In slave mode, McSPI initiates data transfer on the data lines (SPIDAT[1;0]) when it receives an SPI clock (SPICLK) from the external SPI master device.

The controller is able to work with or without a chip select SPIEN depending on MCSPI_MODULCTRL[PIN34] bit setting. It also supports transfers without a dead cycle between two successive words.

26.3.3.1 Dedicated Resources

In slave mode, enabling a channel that is not channel 0 has no effect. Only channel 0 can be enabled. The channel 0, in slave mode has the following resources:

- Its own channel enable, programmable with the bit EN of the register MCSPI_CH0CTRL. This channel should be enabled before transmission and reception. Disabling the channel, outside data word transmission, remains under user responsibility.
- Any of the 4 ports SPIEN[3:0] can be used as a slave SPI device enable. This is programmable with the bits SPIENSLV of the register MCSPI_CH0CONF.
- Its own transmitter register MCSPI_TX on top of the common shift register. If the transmitter register is empty, the status bit TXS of the register MCSPI_CH0STAT is set. When McSPI is selected by an external master (active signal on the SPIEN port assigned to channel 0), the transmitter register content of channel0 is always loaded in shift register whether it has been updated or not. The transmitter register should be loaded before McSPI is selected by a master.
- Its own receiver register MCSPI_RX on top of the common shift register. If the receiver register is full, the status bit RXS of the register MCSPI_CH0STAT is set.

NOTE: The transmitter register and receiver registers of the other channels are not used. Read from or Write in the registers of a channel other than 0 has no effect.

- Its own communication configuration with the following parameters via the register MCSPI_CH0CONF:
  - Transmit/Receive modes, programmable with the bit TRM.
  - Interface mode (Two data pins or Single data pin) and data pins assignment, both programmable with the bits IS and DPE.
  - SPI word length, programmable with the bits WL.
  - SPIEN polarity, programmable with the bit EPOL.
  - SPICLK polarity, programmable with the bit POL.
  - SPICLK phase, programmable with the bit PHA.
  - Use a FIFO buffer or not, programmable with FFER and FFEW, depending on transfer mode TRM.

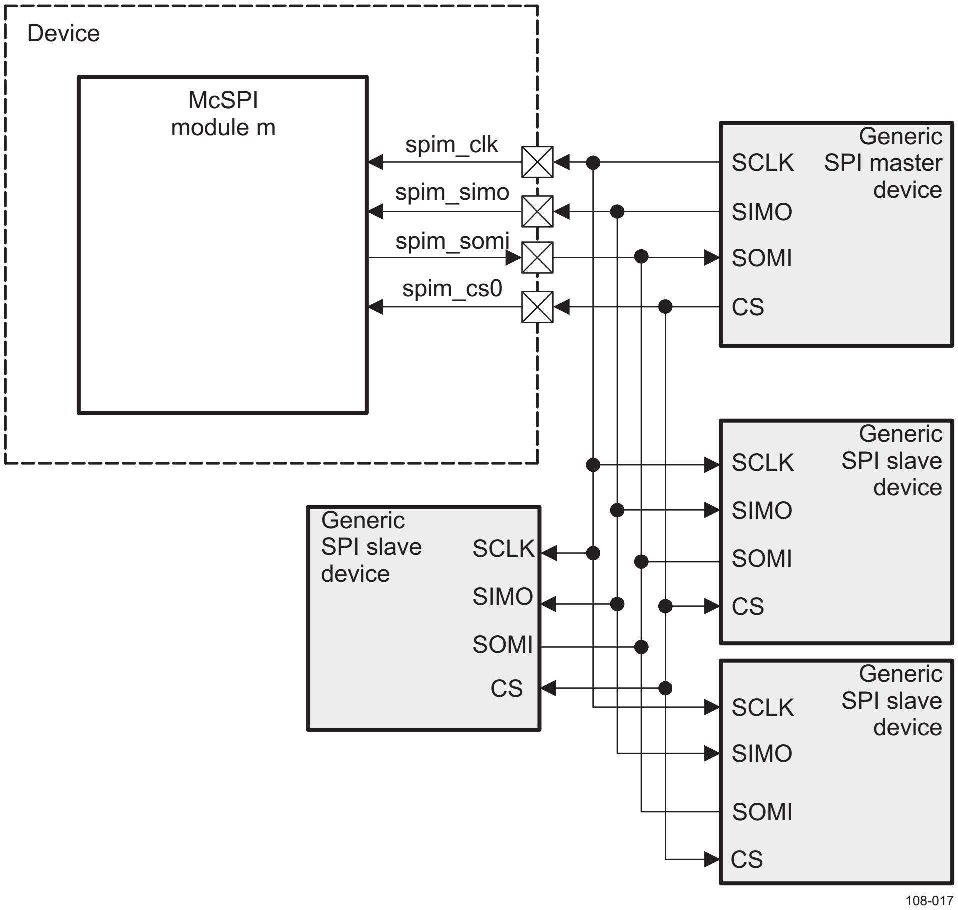
The SPICLK frequency of a transfer is controlled by the external SPI master connected to McSPI. The bits CLKD0 of the MCSPI_CH0CONF register are not used in slave mode.

NOTE: The configuration of the channel can be loaded in the MCSPI_CH0CONF register only when the channel is disabled.

- Two DMA requests events, read and write, to synchronize read/write accesses of the DMA controller with the activity of McSPI. The DMA requests are enabled with the bits DMAR and DMAW of the MCSPI_CH0CONF register.
- Four interrupts events.

Figure 26-23 shows an example of four slaves wired on a single master device.

Figure 26-23. Example of SPI Slave with One Master and Multiple Slave Devices on Channel 0



26.3.3.2 Interrupt Events in Slave Mode

The interrupt events related to the transmitter register state are TX_empty and TX_underflow. The interrupt events related to the receiver register state are RX_full and RX_overflow.

26.3.3.2.1 TX_EMPTY

The event TX_empty is activated when the channel is enabled and its transmitter register becomes empty. Enabling channel automatically raises this event. When FIFO buffer is enabled (MCSPI_CH(i)CONF[FFEW] set to 1), the TX_empty is asserted as soon as there is enough space in buffer to write a number of byte defined by MCSPI_XFERLEVEL[AEL].

Transmitter register must be load to remove source of interrupt and TX_empty interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

When FIFO is enabled, no new TX_empty event will be asserted unless the host performs the number of writes to the transmitter register defined by MCSPI_XFERLEVEL[AEL]. It is the responsibility of the Local Host to perform the right number of writes.

26.3.3.2.2 TX_UNDERFLOW

The event TX_underflow is activated when channel is enabled and if the transmitter register or FIFO (if use of buffer is enabled) is empty (not updated with new data) when an external master device starts a data transfer with McSPI (transmit and receive).

When the FIFO is enabled, the data read while the underflow flag is set will not be the last word written to the FIFO.

The TX_underflow indicates an error (data loss) in slave mode.

To avoid having TX_underflow event at the beginning of a transmission, the event TX_underflow is not activated when no data has been loaded into the transmitter register since channel has been enabled.

TX_underflow interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

26.3.3.2.3 RX_FULL

The event RX_FULL is activated when channel is enabled and receiver becomes filled (transient event). When FIFO buffer is enabled (MCSPI_CH(i)CONF[FFER] set to 1), the RX_FULL is asserted as soon as there is a number of bytes holds in buffer to read defined by MCSPI_XFERLEVEL[AFL].

Receiver register must be read to remove source of interrupt and RX_full interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

When FIFO is enabled, no new RX_FULL event will be asserted unless the host has performed the number of reads from the receive register defined by MCSPI_XFERLEVEL[AFL]. It is the responsibility of Local Host to perform the right number of reads.

26.3.3.2.4 RX_OVERFLOW

The RX0_OVERFLOW event is activated in slave mode in either transmit-and-receive or receive-only mode, when a channel is enabled and the SPI_RX*n* register or FIFO is full when a new SPI word is received. The SPI_RX*n* register is always overwritten with the new SPI word. If the FIFO is enabled, data within the FIFO is overwritten, it must be considered as corrupted. The RX0_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0_OVERFLOW indicates an error (data loss) in slave mode.

The SPI_IRQSTS[3] RX0_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

26.3.3.2.5 End of Word Count

The event end of word (EOW) count is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in MCSPI_XFERLEVEL[WCNT] register. If the value was programmed to 0000h, the counter is not enabled and this interrupt is not generated.

The EOW count interrupt also indicates that the SPI transfer has halted on the channel using the FIFO buffer.

The EOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

26.3.3.3 Slave Transmit-and-Receive Mode

The slave transmit and receive mode is programmable (TRM bit cleared to 0 in the register MCSPI_CH(i)CONF).

After the channel is enabled, transmission and reception proceeds with interrupt and DMA request events.

In slave transmit and receive mode, transmitter register should be loaded before McSPI is selected by an external SPI master device.

Transmitter register or FIFO (if enabled) content is always loaded into the shift register whether it has been updated or not. The event TX_underflow is activated accordingly, and does not prevent transmission.

On completion of SPI word transfer (bit EOT of the register MCSPI_CH(i)STAT is set) the received data is transferred to the channel receive register. This bit is meaningless when using the Buffer for this channel.

The built-in FIFO is available in this mode and can be configured in one data direction, transmit or receive, then the FIFO is seen as a unique 64-byte buffer. It can also be configured in both data directions, transmit and receive, then the FIFO is split into two separate 32-byte buffers with their own address space management.

26.3.3.4 Slave Receive-Only Mode

The slave receive-only mode is programmable (MCSPI_CH(i)CONF[TRM] set to 01).

In receive-only mode, the transmitter register should be loaded before McSPI is selected by an external SPI master device. Transmitter register or FIFO (if enabled) content is always loaded into the shift register whether it has been updated or not. The event TX_underflow is activated accordingly, and does not prevent transmission.

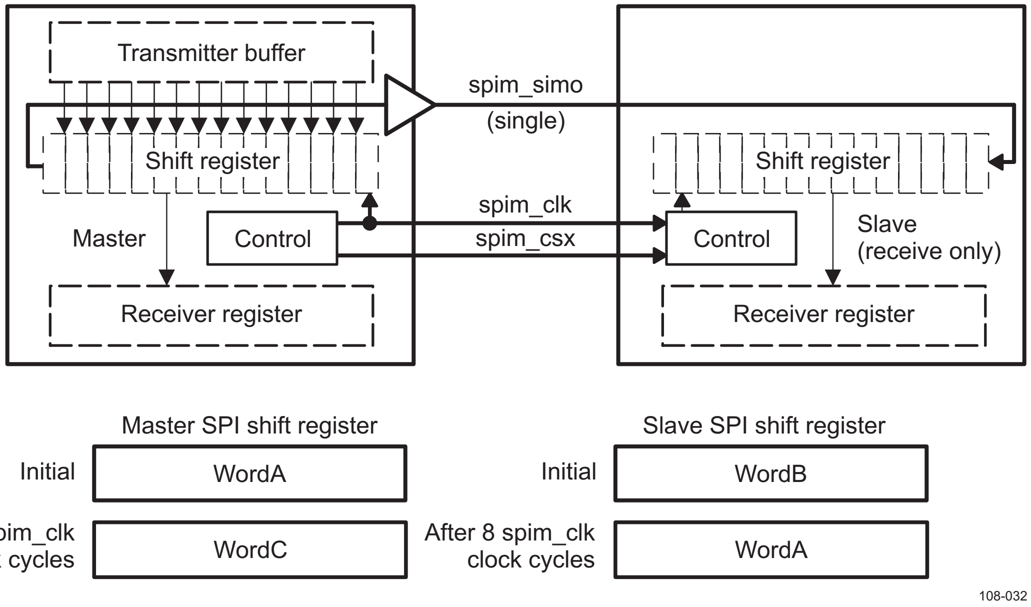
When an SPI word transfer completes (the MCSPI_CH(i)STAT[EOT] bit (with *I* = 0) is set to 1), the received data is transferred to the channel receive register.

To use McSPI as a slave receive-only device with MCSPI_CH(i)CONF[TRM]=00, the user has the responsibility to disable the TX_empty and TX_underflow interrupts and DMA write requests due to the transmitter register state.

On completion of SPI word transfer (bit EOT of the register MCSPI_CH(i)STAT is set) the received data is transferred to the channel receive register. This bit is meaningless when using the Buffer for this channel. The built-in FIFO is available in this mode and can be configured with FFER bit field in the MCSPI_CH(i)CONF register, then the FIFO is seen as a unique 64-byte buffer.

Figure 26-24 shows an example of a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time one bit transfers out from the master, one bit transfers in to the slave. If WordA is 8 bits, then after eight cycles of the serial clock spim_clk, WordA transfers from the master to the slave.

Figure 26-24. SPI Half-Duplex Transmission (Receive-Only Slave)



26.3.3.5 Slave Transmit-Only Mode

The slave transmit-only mode is programmable (MCSPI_CH(i)CONF[TRM] set to 10). This mode eliminates the need for the CPU to read the receiver register (minimizing data movement) when only transmission is meaningful.

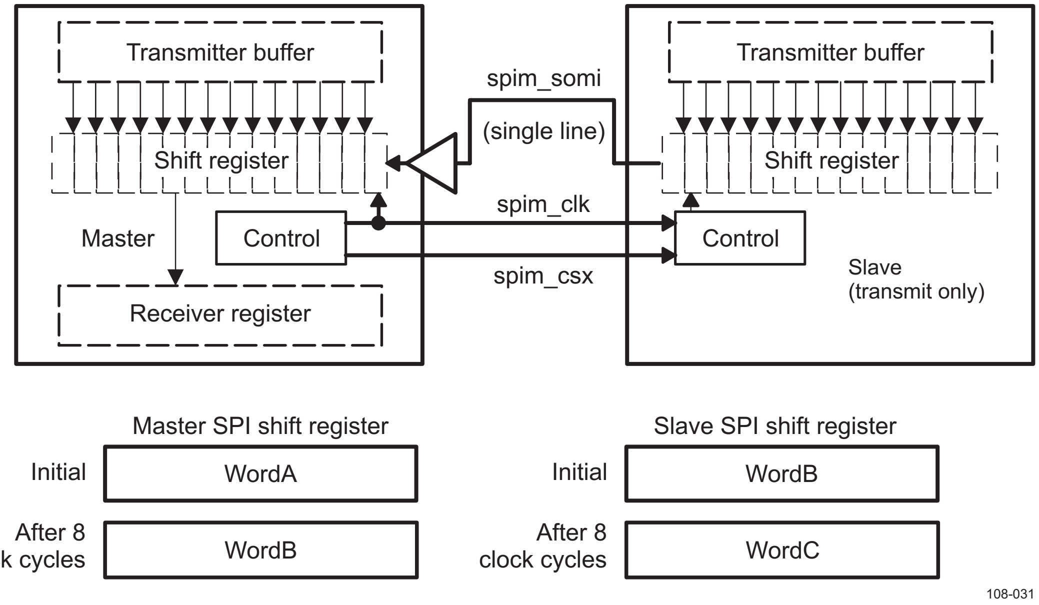
To use McSPI as a slave transmit-only device with MCSPI_CH(i)CONF[TRM]=10, the user should disable the RX_full and RX_overflow interrupts and DMA read requests due to the receiver register state.

On completion of SPI word transfer the bit EOT of the register MCSPI_CH(i)STAT is set. This bit is meaningless when using the Buffer for this channel.

The built-in FIFO is available in this mode and can be configured with FFER bit field in the MCSPI_CH(i)CONF register, then the FIFO is seen as a unique 64-byte buffer.

Figure 26-25 shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave device, one bit transfers in the master. If WordB is 8-bits, then after eight cycles of the serial clock spim_clk, WordB transfers from the slave to the master.

Figure 26-25. SPI Half-Duplex Transmission (Transmit-Only Slave)



26.3.4 Interrupts

According to its transmitter register state and its receiver register state each channel can issue interrupt events if they are enabled.

The interrupt events are listed in the Section 26.3.2.2 and in Section 26.3.3.2.

Each interrupt event has a status bit, in the MCSPI_IRQSTS register, which indicates service is required, and an interrupt enable bit, in the MCSPI_IRQEN register, which enables the status to generate hardware interrupt requests.

When an interrupt occurs and it is later masked (IRQEN), the interrupt line is not asserted again even if the interrupt source has not been serviced.

McSPI supports interrupt driven operation and polling.

26.3.4.1 Interrupt-Driven Operation

Alternatively, an interrupt enable bit, in the MCSPI_IRQEN register, can be set to enable each of the events to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the CPU must:

- Read the MCSPI_IRQSTS register to identify which event occurred,
- Read the receiver register that corresponds to the event in order to remove the source of an RX_full event, or write into the transmitter register that corresponds to the event in order to remove the source of a TX_empty event. No action is needed to remove the source of the events TX_underflow and RX_overflow.
- Write a 1 into the corresponding bit of MCSPI_IRQSTS register to clear the interrupt status, and release the interrupt line.

The interrupt status bit should always be reset after the channel is enabled and before the event is enabled as an interrupt source.

26.3.4.2 Polling

When the interrupt capability of an event is disabled in the MCSPI_IRQEN register, the interrupt line is not asserted and:

- The status bits in the MCSPI_IRQSTS register can be polled by software to detect when the corresponding event occurs.
- Once the expected event occurs, CPU must read the receiver register that corresponds to the event in order to remove the source of an RX_full event, or write into the transmitter register that corresponds to the event in order to remove the source of a TX_empty event. No action is needed to remove the source of the events TX_underflow and RX_overflow.
- Writing a 1 into the corresponding bit of MCSPI_IRQSTS register clears the interrupt status and does not affect the interrupt line state.

26.3.5 DMA Requests

McSPI can be interfaced with a DMA controller. At system level, the advantage is to free the local host of the data transfers.

According to its transmitter register state, its receiver register state or FIFO level (if use of buffer for the channel) each channel can issue DMA requests if they are enabled.

The DMA requests need to be disabled in order to get TX and RX interrupts, in order to define either the end of the transfer or the transfer of the last words for the modes listed below:

- Master transmit-only
- Master normal receive-only mode
- Master turbo receive-only mode
- Slave transmit-only

There are two DMA request lines per channel. The management of DMA requests differ according to use of FIFO buffer or not.

26.3.5.1 FIFO Buffer Disabled

The DMA Read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel. DMA Read request can be individually masked with the bit DMAR of the register MCSPI_CH(i)CONF. The DMA Read request line is de-asserted on read completion of the receive register of the channel.

The DMA Write request line is asserted when the channel is enabled and the transmitter register of the channel is empty. DMA Write request can be individually masked with the bit DMAW of the register MCSPI_CH(i)CONF. The DMA Write request line is de-asserted on load completion of the transmitter register of the channel.

Only one SPI word can be transmitted/received per OCP bus access to write/read the transmit or receive register.

26.3.5.2 FIFO Buffer Enabled

The DMA Read request line is asserted when the channel is enabled and a number of bytes defined in MCSPI_XFERLEVEL[AFL] bit field is hold in FIFO buffer for the receive register of the channel. DMA Read request can be individually masked with the bit DMAR of the register MCSPI_CH(i)CONF. The DMA Read request line is de-asserted on the first SPI word read completion of the receive register of the channel. No new DMA request will be asserted again as soon as user has not performed the right number of read accesses defined by MCSPI_XFERLEVEL[AFL] it is under user responsibility.

The DMA Write request line is asserted when the channel is enabled and the number of bytes hold in FIFO buffer is below the level defined by the MCSPI_XFERLEVEL[AEL] bit field. DMA Write request can be individually masked with the bit DMAW of the register MCSPI_CH(i)CONF. The DMA Write request line is de-asserted on load completion of the first SPI word in the transmitter register of the channel. No new DMA request will be asserted again as soon as user has not performed the right number of write accesses defined by MCSPI_XFERLEVEL[AEL] it is under user responsibility.

Only one SPI word can be transmitted/received per OCP bus access to write/read the transmit or receive FIFO.

26.3.5.3 DMA 256-Bit Aligned Addresses

The controller has two registers, MCSPI_DAFTX and MCSPI_DAFRX, used only with an enabled channel which manages the FIFO to be compliant the a DMA handler providing only 256-bit aligned addresses.

This features is activated when the bit field MCSPI_MODULCTRL[FDAA] is set to ‘1’ and only one enabled channel have its bit field MCSPI_CH(i)CONF[FFEW] or MCSPI_CH(i)CONF[FFER] enabled.

In this case the registers MCSPI_TX(i) and MCSPI_RX(i) are not used and data is managed through registers MCSPI_DAFTX and MCSPI_DAFRX.

26.3.6 Emulation Mode

The MReqDebug input differentiates a regular access of a processor (application access), from an emulator access.

Application access: MReqDebug = 0

In functional mode, the consequences of a read of a receiver register MCSPI_RX(i) are the following:

- The source of an RX(i)_Full event in the MCSPI_IRQSTS register is removed, if it was enabled in the MCSPI_IRQEN register.
- The RX(i)S status bit in the MCSPI_IRQSTS register is cleared.
- In master mode, depending on the round robin arbitration, and the transmitter register state, the channel may access to the shift register for transmission/reception.

Emulator access: MReqDebug = 1

In emulation mode, McSPI behavior is the same as in functional mode but a read of a receiver register MCSPI_RX(i) is not intrusive:

- MCSPI_RX(i) is still considered as not read. When the FIFO buffer is enabled, pointers are not updated.
- The source of an RX(i)_Full event in the MCSPI_IRQSTS register is not removed. The RX(i)S status bit in the MCSPI_CH(i)STAT register is held steady.

In emulation mode, as in functional mode, based on the ongoing data transfers, the status bits of the MCSPI_CH(i)STAT register may be optionally updated, the interrupt and DMA request lines may be optionally asserted.

26.3.7 Power Saving Management

Independently of the module operational modes (Transmit and/or Receive), two modes of operations are defined from a power management perspective: normal and idle modes.

The two modes are temporally fully exclusive.

26.3.7.1 Normal Mode

Both the Interface, or OCP, clock and SPI clock (CLKSPIREF) provided to McSPI must be active for both master and slave modes. The auto-gating of the module OCP clock and SPI clock occurs when the following conditions are met:

- The bit AutoIdle of the register MCSPI_SYSCONFIG is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the SPI is not selected by the external SPI master device and no OCP accesses.

Autogating of the module OCP clock and SPI clock stops when the following conditions are met:

- In master mode, an OCP access occurs.
- In slave mode, an OCP access occurs or McSPI is selected by an external SPI master device.

26.3.7.2 Idle Mode

The OCP clock and SPI clock provided to McSPI may be switched off on system power manager request and switched back on module request.

McSPI is compliant with the power management handshaking protocol: idle request from the system power manager, idle acknowledgement from McSPI.

The idle acknowledgement in response to an idle request from the system power manager varies according to a programmable mode in the MCSPI_SYSCONFIG register: No idle mode, force idle mode, and smart idle mode.

- When programmed for no idle mode (the bit SIdleMode of the register MCSPI_SYSCONFIG is set to “01”), the module ignores the system power manager request, and behaves normally, as if the request was not asserted.
- When programmed for smart idle mode (the bit SIdleMode of the register MCSPI_SYSCONFIG is set to “10”), the module acknowledges the system power manager request according to its internal state.
- When programmed for force idle mode (the bit SIdleMode of the register MCSPI_SYSCONFIG is set to “00”), the module acknowledges the system power manager request unconditionally.

The OCP clock will be optionally switched off, during the smart idle mode period, if the bit ClockActivity of the register MCSPI_SYSCONFIG is set.

The SPI clock will be optionally switched off, during the smart idle mode period, if the second bit ClockActivity of the register MCSPI_SYSCONFIG is set.

McSPI assumes that both clocks may be switched off whatever the value set in the field ClockActivity of the register MCSPI_SYSCONFIG.

26.3.7.2.1 Transitions from Normal Mode to Smart-Idle Mode

The module detects an idle request when the synchronous signal IdleReq is asserted.

When IdleReq is asserted, any access to the module will generate an error as long as the OCP clock is alive.

When configured as a slave device, McSPI responds to the idle request by asserting the SIdleAck signal (idle acknowledgement) only after completion of the current transfer (SPIEN slave selection signal deasserted by the external master) and if interrupt or DMA request lines are not asserted.

As a master device, McSPI responds to the idle request by asserting the SIdleAck signal (idle acknowledgement) only after completion of all the channel data transfers and if interrupt or DMA request lines are not asserted.

As long as SIdleAck is not asserted, if an event occurs, the module can still generate an interrupt or a DMA request after IdleReq assertion. In this case, the module ignores the idle request and SIdleAck will not get asserted: The system power manager will abort the power mode transition procedure. It is then the responsibility of the system to de-assert IdleReq before attempting to access the module.

When SIdleAck is asserted, the module does not assert any new interrupt or DMA request.

26.3.7.2.2 Transition From Smart-Idle Mode to Normal mode

McSPI detects the end of the idle period when the idle request signal (IdleReq) is deasserted.

Upon IdleReq de-assertion, the module switches back to normal mode and de-asserts SIdleAck signal. The module is fully operational.

26.3.7.2.3 Force-Idle Mode

Force-idle mode is enabled as follows:

- The bit SIdleMode of the register MCSPI_SYSCONFIG is cleared to “00” (Force Idle).

  The force idle mode is an idle mode where McSPI responds unconditionally to the idle request by asserting the SIdleAck signal and by deasserting unconditionally the interrupt and DMA request lines if asserted.

  The transition from normal mode to idle mode does not affect the interrupt event bits of the MCSPI_IRQSTS register.

  In force-idle mode, the module is supposed to be disabled at that time, so the interrupt and DMA request lines are likely deasserted. OCP clock and SPI clock provided to McSPI can be switched off.

  An idle request during an SPI data transfer can lead to an unexpected and unpredictable result, and is under software responsibility.

  Any access to the module in force idle mode will generate an error as long as the OCP clock is alive and IdleReq is asserted.

The module exits the force idle mode when:

- The idle request signal (IdleReq) is de-asserted.

  Upon IdleReq de-assertion, the module switches back to normal mode and de-asserts SIdleAck signal. The module is fully operational. The interrupt and DMA request lines are optionally asserted a clock cycle later.

26.3.8 System Test Mode

McSPI is in system test mode (SYSTEST) when the bit System_Test of the register MCSPI_MODULCTRL is set.

The SYSTEST mode is used to check in a very simple manner the correctness of the system interconnect either internally to interrupt handler, or power manager, or externally to SPI I/Os.

I/O verification can be performed in SYSTEST mode by toggling the outputs and capturing the logic state of the inputs. (See MCSPI_SYST register definition in Section 26.4.1)

26.3.9 Reset

26.3.9.1 Internal Reset Monitoring

The module is reset by the hardware when an active-low reset signal, synchronous to the OCP interface clock is asserted on the input pin RESETN.

This hardware reset signal has a global reset action on the module. All configuration registers and all state machines are reset, in all clock domains.

Additionally, the module can be reset by software through the bit SoftReset of the register MCSPI_SYSCONFIG. This bit has exactly the same action on the module logic as the hardware RESETN signal. The register MCSPI_SYSCONFIG is not sensitive to software reset. The SoftReset control bit is active high. The bit is automatically reset to 0 by the hardware.

A global ResetDone status bit is provided in the status register MCSPI_SYSSTS. This bit is set to 1 when all the different clock domains resets (OCP domain and SPI domains) have been released (logical AND).

The global ResetDone status bit can be monitored by the software to check if the module is ready-to-use following a reset (either hardware or software).

The clock CLKSPIREF must be provided to the module, in order to allow the ResetDone status bit to be set.

When used in slave mode, the clock CLKSPIREF is needed only during the reset phase. The clock CLKSPIREF can be switched off after the ResetDone status is set.

26.3.9.2 Reset Values of Registers

The reset values of registers and signals are described in .

26.3.10 Access to Data Registers

This section details the supported data accesses (read or write) from/to the data receiver registers MCSPI_RX(i) and data transmitter registers MCSPI_TX(i).

Supported access:

McSPI supports only one SPI word per register (receiver or transmitter) and does not support successive 8-bit or 16-bit accesses for a single SPI word.

The SPI word received is always right justified on LSbit of the 32bit register MCSPI_RX(i), and the SPI word to transmit is always right justified on LSbit of the 32bit register MCSPI_TX(i).

The upper bits, above SPI word length, are ignored and the content of the data registers is not reset between the SPI data transfers.

The coherence between the number of bits of the SPI Word, the number of bits of the access and the enabled byte remains under the user’s responsibility. Only aligned accesses are supported.

In Master mode, data should not be written in the transmit register when the channel is disabled.

26.3.11 Programming Aid

26.3.11.1 Module Initialization

- Hard or soft reset.
- Read MCSPI_SYSSTS.
- Check if reset is done.
- Module configuration: (a) Write into MCSPI_MODULCTRL (b) Write into MCSPI_SYSCONFIG.
- Before the ResetDone bit is set, the clocks CLK and CLKSPIREF must be provided to the module.
- To avoid hazardous behavior, it is advised to reset the module before changing from MASTER mode to SLAVE mode or from SLAVE mode to MASTER mode.

26.3.11.2 Common Transfer Sequence

McSPI module allows the transfer of one or several words, according to different modes:

- MASTER, MASTER Turbo, SLAVE
- TRANSMIT - RECEIVE, TRANSMIT ONLY, RECEIVE ONLY
- Write and Read requests: Interrupts, DMA
- SPIEN lines assertion/deassertion: automatic, manual

For all these flows, the host process contains the main process and the interrupt routines. The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

In multi-channel master mode, the flows of different channels can be run simultaneously.

26.3.11.3 Main Program

- Interrupt Initialization: (a) Reset status bits in MCSPI_IRQSTS (b) Enable interrupts in MCSPI_IRQENA.
- Channel Configuration: Write MCSPI_CH(i)CONF.
- Start the channel: Write 0000 0001h in MCSPI_CH(i)CTRL.
- First write request: TX empty - Generate DMA write event/ polling TX empty flag by CPU to write First transmit word into MCSPI_TX(i).
- End of transfer: Stop the channel by writing 0000 0000h in MCSPI_CH(i)CTRL

The end of transfer depends on the transfer mode.

In multi-channel master mode, be careful not to overwrite the bits of other channels when initializing MCSPI_IRQSTS and MCSPI_IRQEN.

26.3.12 Interrupt and DMA Events

McSPI has two DMA requests (Rx and Tx) per channel. It also has one interrupt line for all the interrupt requests.

26.4 McSPI Registers

26.4.1 MCSPI Registers

Table 26-10 lists the memory-mapped registers for the MCSPI. All register offset addresses not listed in Table 26-10 should be considered as reserved locations and the register contents should not be modified.

Table 26-10. MCSPI Registers

Offset	Acronym	Register Name	Section

</table>

Table 26-15. MCSPI_SYSCONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-10	RESERVED	R/W	0h	Reads returns 0
9-8	CLOCKACTIVITY	R/W	0h	Clocks activity during wake up mode period 0h (R/W) = OCP and Functional clocks may be switched off. 1h (R/W) = OCP clock is maintained. Functional clock may be switched-off. 2h (R/W) = Functional clock is maintained. OCP clock may be switched-off. 3h (R/W) = OCP and Functional clocks are maintained.
7-5	RESERVED	R/W	0h	Reads returns 0
4-3	SIDLEMODE	R/W	2h	Power management 0h (R/W) = If an idle request is detected, the McSPI acknowledges it unconditionally and goes in Inactive mode. Interrupt, DMA requests and wake up lines are unconditionally de-asserted and the module wakeup capability is deactivated even if the bit MCSPI_SYSCONFIG[EnaWakeUp] is set. 1h (R/W) = If an idle request is detected, the request is ignored and the module does not switch to wake up mode, and keeps on behaving normally. 2h (R/W) = If an idle request is detected, the module will switch to idle mode based on its internal activity. The wake up capability cannot be used. 3h (R/W) = If an idle request is detected, the module will switch to idle mode based on its internal activity, and the wake up capability can be used if the bit MCSPI_SYSCONFIG[EnaWakeUp] is set.
2	ENAWAKEUP	R/W	1h	WakeUp feature control 0h (R/W) = WakeUp capability is disabled 1h (R/W) = WakeUp capability is enabled
1	SOFTRESET	R/W	0h	Software reset. During reads it always returns 0. 0h (R/W) = (write) Normal mode 1h (R/W) = (write) Set this bit to 1 to trigger a module reset.The bit is automatically reset by the hardware.

Table 26-15. MCSPI_SYSCONFIG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	AUTOIDLE	R/W	1h	Internal OCP Clock gating strategy 0h (R/W) = OCP clock is free-running 1h (R/W) = Automatic OCP clock gating strategy is applied, based on the OCP interface activity

26.4.1.6 MCSPI_SYSSTS Register (Offset = 114h) [reset = 0h]

Register mask: FFFFFFFFh

MCSPI_SYSSTS is shown in Figure 26-31 and described in Table 26-16.

Return to Summary Table.

This register provides status information about the module excluding the interrupt status information

Table 26-20. MCSPI_SYST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-12	RESERVED	R/W	0h	Reads returns 0
11	SSB	R/W	0h	Set status bit 0h (R/W) = No action. Writing 0 does not clear already set status bits; This bit must be cleared prior attempting to clear a status bit of the <MCSPI_IRQSTATUS> register. 1h (R/W) = Force to 1 all status bits of MCSPI_IRQSTATUS register. Writing 1 into this bit sets to 1 all status bits contained in the <MCSPI_IRQSTATUS> register.
10	SPIENDIR	R/W	0h	Set the direction of the SPIEN [3:0] lines and SPICLK line 0h (R/W) = output (as in master mode) 1h (R/W) = input (as in slave mode)
9	SPIDATDIR1	R/W	0h	Set the direction of the SPIDAT[1] 0h (R/W) = output 1h (R/W) = input
8	SPIDATDIR0	R/W	0h	Set the direction of the SPIDAT[0] 0h (R/W) = output 1h (R/W) = input
7	WAKD	R/W	0h	SWAKEUP output (signal data value of internal signal to system). The signal is driven high or low according to the value written into this register bit. 0h (R/W) = The pin is driven low. 1h (R/W) = The pin is driven high.
6	SPICLK	R/W	0h	SPICLK line (signal data value) If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the CLKSPI line (high or low), and a write into this bit has no effect. If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the CLKSPI line is driven high or low according to the value written into this register.

Table 26-20. MCSPI_SYST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	SPIDAT_1	R/W	0h	SPIDAT[1] line (signal data value) If MCSPI_SYST[SPIDATDIR1] = 0 (output mode direction), the SPIDAT[1] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIDATDIR1] = 1 (input mode direction), this bit returns the value on the SPIDAT[1] line (high or low), and a write into this bit has no effect.
4	SPIDAT_0	R/W	0h	SPIDAT[0] line (signal data value) If MCSPI_SYST[SPIDATDIR0] = 0 (output mode direction), the SPIDAT[0] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIDATDIR0] = 1 (input mode direction), this bit returns the value on the SPIDAT[0] line (high or low), and a write into this bit has no effect.
3	SPIEN_3	R/W	0h	SPIEN[3] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[3] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[3] line (high or low), and a write into this bit has no effect.
2	SPIEN_2	R/W	0h	SPIEN[2] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[2] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[2] line (high or low), and a write into this bit has no effect.
1	SPIEN_1	R/W	0h	SPIEN[1] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[1] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[1] line (high or low), and a write into this bit has no effect.
0	SPIEN_0	R/W	0h	SPIEN[0] line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the SPIENT[0] line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the SPIEN[0] line (high or low), and a write into this bit has no effect.

26.4.1.11 MCSPI_MODULCTRL Register (Offset = 128h) [reset = 4h]

Register mask: FFFFFFFFh

MCSPI_MODULCTRL is shown in Figure 26-36 and described in Table 26-21.

Return to Summary Table.

This register is dedicated to the configuration of the serial port interface.

Figure 26-36. MCSPI_MODULCTRL Register

Table 26-21. MCSPI_MODULCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-9	RESERVED	R/W	0h	Reads returns 0
8	FDAA	R/W	0h	FIFO DMA Address 256-bit aligned This register is used when a FIFO is managed by the module and DMA connected to the controller provides only 256 bit aligned address. If this bit is set the enabled channel which uses the FIFO has its datas managed through MCSPI_DAFTX and MCSPI_DAFRX registers instead of MCSPI_TX(i) and MCSPI_RX(i) registers. 0h (R/W) = FIFO data managed by MCSPI_TX(i) and MCSPI_RX(i) registers. 1h (R/W) = FIFO data managed by MCSPI_DAFTX and MCSPI_DAFRX registers.
7	MOA	R/W	0h	Multiple word ocp access: This register can only be used when a channel is enabled using a FIFO. It allows the system to perform multiple SPI word access for a single 32-bit OCP word access. This is possible for WL < 16. 0h (R/W) = Multiple word access disabled 1h (R/W) = Multiple word access enabled with FIFO
6-4	INITDLY	R/W	0h	Initial spi delay for first transfer: This register is an option only available in SINGLE master mode, The controller waits for a delay to transmit the first spi word after channel enabled and corresponding TX register filled. This Delay is based on SPI output frequency clock, No clock output provided to the boundary and chip select is not active in 4 pin mode within this period. 0h (R/W) = No delay for first spi transfer. 1h (R/W) = 4ClkDly : The controller wait 4 spi bus clock 2h (R/W) = 8ClkDly : The controller wait 8 spi bus clock 3h (R/W) = 16ClkDly : The controller wait 16 spi bus clock 4h (R/W) = 32ClkDly : The controller wait 32 spi bus clock

Table 26-21. MCSPI_MODULCTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	SYSTEM_TEST	R/W	0h	Enables the system test mode 0h (R/W) = Functional mode 1h (R/W) = System test mode (SYSTEST)
2	MS	R/W	1h	Master/ Slave 0h (R/W) = Master - The module generates the SPICLK and SPIEN[3:0] 1h (R/W) = Slave - The module receives the SPICLK and SPIEN[3:0]
1	PIN34	R/W	0h	Pin mode selection: This register is used to configure the SPI pin mode, in master or slave mode. If asserted the controller only use SIMO,SOMI and SPICLK clock pin for spi transfers. 0h (R/W) = 4PinMode : SPIEN is used as a chip select. 1h (R/W) = 3PinMode : SPEIN is not used. In this mode all related option to chip select have no meaning.
0	SINGLE	R/W	0h	Single channel / Multi Channel (master mode only) 0h (R/W) = More than one channel will be used in master mode. 1h (R/W) = Only one channel will be used in master mode. This bit must be set in Force SPIEN mode.

26.4.1.12 MCSPI_CH0CONF Register (Offset = 12Ch) [reset = 00060000h]

Register mask: FFFFFFFFh

MCSPI_CH0CONF is shown in Figure 26-37 and described in Table 26-22.

Return to Summary Table.

This register is dedicated to the configuration of the channel 0

26.4.1.15 MCSPI_TX0 Register (Offset = 138h) [reset = 0h]

Register mask: FFFFFFFFh

MCSPI_TX0 is shown in Figure 26-40 and described in Table 26-25.

Return to Summary Table.

The McSPI channel FIFO transmit buffer register (MCSPI_TXx) contains a single McSPI word to transmit through the serial link, whatever the SPI word length is. Little endian host access SPI 8 bit word on 0; big endian host accesses on 3h. SPI words are transferred with MSB first. Refer to section 26.3.10 "Access to Data Registers" for more information.

26.4.1.32 MCSPI_XFERLEVEL Register (Offset = 17Ch) [reset = 0h]

Register mask: FFFFFFFFh

MCSPI_XFERLEVEL is shown in Figure 26-57 and described in Table 26-42.

Return to Summary Table.

This register provides transfer levels needed while using FIFO buffer during transfer.

Figure 26-57. MCSPI_XFERLEVEL Register

Bit	Field	Type	Reset	Description
31-16	WCNT	R/W	0h	Spi word counterThis register holds the programmable value of number of SPI word to be transferred on channel which is using the FIFO buffer.When transfer had started, a read back in this register returns the current SPI word transfer index. 0h (R/W) = Counter not used 1h (R/W) = 1word : one word FFFEh (R/W) = 65534word : 65534 spi word FFFFh (R/W) = 65535word : 65535 spi word
15-8	AFL	R/W	0h	Buffer Almost Full This register holds the programmable almost full level value used to determine almost full buffer condition. If the user wants an interrupt or a DMA read request to be issued during a receive operation when the data buffer holds at least n bytes, then the buffer MCSPI_MODULCTRL[AFL] must be set with n-1.The size of this register is defined by the generic parameter FFNBYTE. 0h (R/W) = 1byte : one byte 1h (R/W) = 2bytes : 2 bytes FEh (R/W) = 255bytes : 255bytes FFh (R/W) = 256bytes : 256bytes
7-0	AEL	R/W	0h	Buffer Almost EmptyThis register holds the programmable almost empty level value used to determine almost empty buffer condition. If the user wants an interrupt or a DMA write request to be issued during a transmit operation when the data buffer is able to receive n bytes, then the buffer MCSPI_MODULCTRL[AEL] must be set with n-1. 0h (R/W) = 1byte : one byte 1h (R/W) = 2bytes : 2 bytes FEh (R/W) = 255bytes : 255 bytes FFh (R/W) = 256bytes : 256bytes

26.4.1.33 MCSPI_DAFTX Register (Offset = 180h) [reset = 0h]

Register mask: FFFFFFFFh

MCSPI_DAFTX is shown in Figure 26-58 and described in Table 26-43.

Return to Summary Table.

This register contains the SPI words to transmit on the serial link when FIFO used and DMA address is aligned on 256 bit.This register is an image of one of MCSPI_TX(i) register corresponding to the channel which have its FIFO enabled.

QSPI

This chapter describes the QSPI of the device.

Topic **Page**

27.1 Introduction

27.1.1 QSPI Features

The main features of the QSPI include:

- Programmable divider for serial data clock generation
- Six pin interface (DCLK, CS_N, DOUT, DIN, QDIN1, QDIN2)
- Programmable data length (No. of bits from 1-32)
- 4 external chip select signals
- Support for 3-, 4- or 6-pin SPI interface
  - 3-pin mode uses spi_dout as inout/spi_din not used
  - 4-pin mode for dual read uses spi_dout as in/spi_din as in
  - 6-pin mode uses spi_dout as in/spi_din as in/spi_qdin0 as in/spi_qdin1 as in
- Programmable transfer or frame size (No. of words from 1 to 4096)
- Optional interrupt generation on word or frame completion
- Programmable CS_N to DOUT delay from 0 to 3 DCLKs
- Programmable signal polarities
- Programmable active clock edge
- Software controllable interface allowing for any type of SPI transfer
- Control through OCP configuration port access

27.1.2 Unsupported Features

The QSPI module does not support the following features.

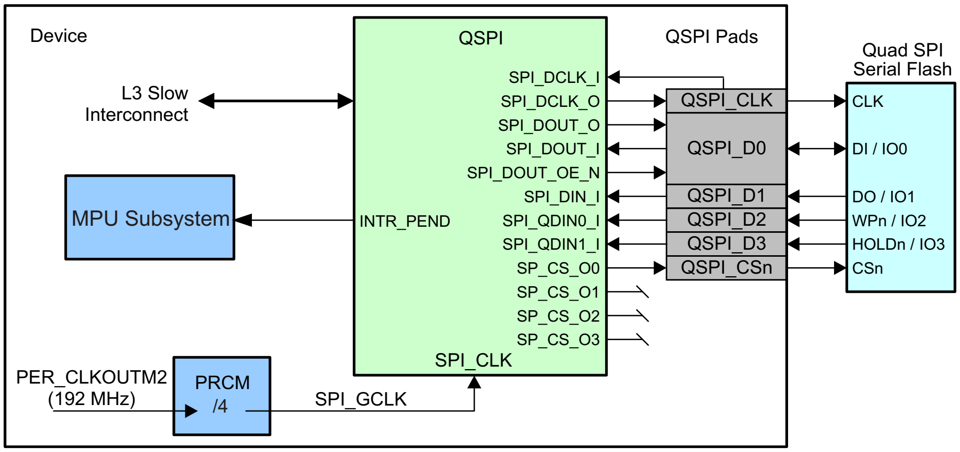
Table 27-1. Unsupported QSPI Features

Feature	Reason
External CS1-3	Not pinned out
Slave wakeup	Not connected

27.2 Integration

The QSPI module allows for single, dual or quad read access to external devices. The module supports a memory mapped interface, which provides a direct memory interface for accessing data from the external SPI device, simplifying software requirements. It is an SPI master only.

Figure 27-1. QSPI Integration



27.2.1 QSPI Connectivity Attributes

The general connectivity attributes for the QSPI module are shown in Table 27-2.

Table 27-2. QSPI Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3S_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart idle
Interrupt Requests	1 interrupt to MPU Subsystem (QSPIINT), PRU-ICSS
DMA Requests	None
Physical Address	L3 slow slave port Memory and control register regions qualified with MAddressSpace[2:0] bits

27.2.2 QSPI Clock and Reset Management

The QSPI has an OCP clock and a separate functional clock.

Table 27-3. QSPI Clock Signals

Clock Signal	Maximum Frequency	Reference Source	Comments
clk Interface / functional clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l3s_gclk from PRCM
spi_clk Functional clock	48 MHz	PER_CLKOUTM2 / 4	pd_per_spi_gclk from PRCM

27.2.3 QSPI Pin List

The external pins for the QSPI module are shown in Table 27-4.

Table 27-4. QSPI Pin List

Pin	Type	Description
QSPI_CLK[1]	O	QSPI output clock
QSPI_CS	O	QSPI chip select
QSPI_DATA[3:0]	I/O	QSPI data input (data[3:0]) and output (data0 only)

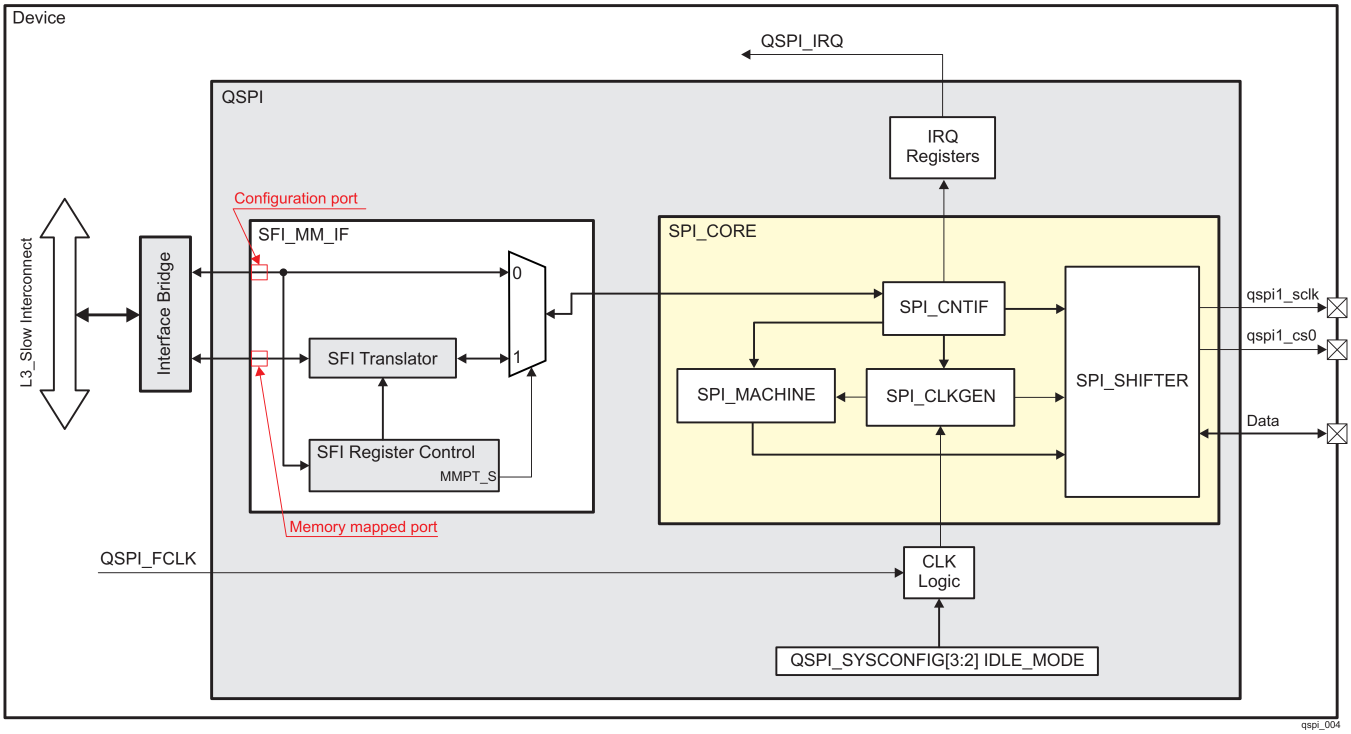
[1] These signals are also used as inputs to re-time or sync data. The associated CONF_<module>_pin_RXACTIVE bit for these signals must be set to 1 to enable the inputs back to the module. It is also recommended to place a 33-ohm resistor in series (close to the processor) on each of these signals to avoid signal reflections.

27.3 QSPI Functional Description

27.3.1 QSPI Block Diagram

Iinitial device boot from external SPI flash memory can be accomplished through the QSPI module. The interface is a simple 4-wire SPI used for control or data transfers. The QSPI also supports a 3-wire SPI protocol where the qspi1_d[0] signal is used as a bidirectional for reads and writes. In addition, a 6-wire mode can be used to support quad read devices. Figure 27-2 shows the QSPI block diagram.

Figure 27-2. QSPI Block Diagram



The QSPI is composed of two blocks. The first one is the SFI memory-mapped interface (SFI_MM_IF) and the second one is the SPI core (SPI_CORE). The SFI_MM_IF block is associated only with SPI flash memories and is used for specifying typical for the SPI flash memories settings (read or write command, number of address and dummy bytes, and so on) unlike the SPI_CORE block, which is associated with the SPI interface itself and is used to configure typical SPI settings (chip-select polarity, serial clock inactive state, SPI clock mode, length of the words transferred, and so on).

The SFI_MM_IF comprises the following two subblocks:

- SFI register control
- SFI translator

The SPI_CORE comprises the following four subblocks:

- SPI control interface (SPI_CNTIF)
- SPI clock generator (SPI_CLKGEN)
- SPI control state machine (SPI_MACHINE)
- SPI data shifter (SPI_SHIFTER)

In addition, an interface bridge connects the two ports (configuration port and memory-mapped port) of the SFI_MM_IF block to the L3_Slow interconnect. There are no software controls associated with this interface bridge.

The QSPI supports long transfers through a frame-style sequence. In its generic SPI use mode, a word can be defined up to 128 bits and multiple words can be transferred during a single access. For each word, a device initiator must read or write the new data and then tell the QSPI to continue the current operation. Using this sequence, a maximum of 4096 128-bit words can be transferred in a single SPI read or write operation. This allows great flexibility when connecting the QSPI to various types of devices.

As opposed to the generic SPI use mode, the communication with serial flash-type devices requires sending a byte command, followed by sending bytes of data. Commands can be sent through the SPI_CORE block to communicate with a serial flash device; however, it is easier to do this using the SFI_MM_IF block because it is intended to ease the communication with serial flash devices. If the SPI_CORE is used to communicate with a serial flash device, software must load the command into the SPI data transfer register with additional configuration fields, perform the byte transfer, then place the data to be sent (or configure for receive) along with additional configuration fields, and perform that transfer. Reads and writes to serial flash devices are more specific. First, the read or write command byte is sent, followed by 1 to 4 bytes of address (corresponding to the address to read/write), then followed by the data write/receive phase. Data is always sent byte oriented. When the address is loaded, data can be continuously read or written, and the address will automatically increment to each byte address internally to the serial flash device.

NOTE: The SFI_MM_IF block only allows reading and writing to an externaly connected SPI flash device. The SFI_MM_IF block does not allow reads or writes to internal configuration and status registers of the SPI flash device. These registers must be accessed through the features of the SPI_CORE block.

27.3.1.1 SFI Register Control

The SFI register control block consists of the following two configuration registers:

- QSPI_SETUP0_REG
- QSPI_SWITCH_REG

The first four registers let the user define the following:

- Byte command for a serial flash read specified by the QSPI_SETUP0_REG[7:0] RCMD bit field
- Byte command for a serial flash write specified by the QSPI_SETUP0_REG[23:16] WCMD bit field
- Number of address bytes required for the particular type of serial flash specified by the QSPI_SETUP0_REG[9:8] NUM_A_BYTES bit field
- Number of “dummy bytes” that may be needed to support the fast read mode function of some serial flash devices. The QSPI_SETUP0_REG[11:10] NUM_D_BYTES bit field specifies the number of "dummy bits." In addition, the QSPI_SETUP0_REG[28:24] NUM_D_BITS bit field can also specify the number of "dummy bits."
- Whether the read command is single (normal), dual, or quad read mode command. This is specified by the QSPI_SETUP0_REG[13:12] READ_TYPE bit field.

The QSPI_SWITCH_REG register acts as a static switch which allows the configuration port (shown in Figure 27-2) to connect directly to the SPI_CORE block, or allows the memory-mapped port (also shown in Figure 27-2) to connect to the SPI_CORE block. This is done using the QSPI_SWITCH_REG[0] MMPT_S bit.

In addition, the QSPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

27.3.1.2 SFI Translator

The SFI translator block represents an FSM which, based on the configuration information loaded into the SFI register control block, converts each input read/write sequence into an SPI_CORE configuration sequence for access to the external serial flash memory.

A read sequence is converted into the following actions:

1. SPI chip-select goes active.
2. Read command byte is issued.
3. 1 to 4 address bytes, which correspond to the first address supplied, are issued.
4. 0 to 3 dummy bytes are issued, if “fast read” is supported.
5. Data bytes are read from the external SPI flash memory.
6. SPI chip-select goes inactive.

For linear addressing mode, action 5 is repeated until the byte count to be transferred reaches zero.

A write sequence is identical to a read sequence, except that a write sequence does not use dummy bytes.

Another important aspect with regard to writes is that a serial flash memory location can only be written to if the bits are erased in advance. Erased means the bits are set to 1. This means that writing only changes 1 contents to 0. It is not possible with this write to change the contents of a bit from 0 to 1. An erase command must be performed to do this operation. Erase commands cannot be executed on single byte locations. Depending on device types, there are page, block, and chip erase commands. To perform an erase command, the particular command must be sent over the SPI bus, and an internal register of the serial flash device must then be polled to determine when the erase completes. The erases must be done through the configuration port by software before performing any writes through the memory-mapped port. This means that writes are passed through to the serial flash device, but if the memory locations being modified are not properly erased before the write, the contents may not result in what was sent.

27.3.1.3 SPI Control Interface

The SPI control interface contains configuration registers used to configure the SPI core functionality of the QSPI. This block maintains all configuration settings for the SPI core (that is, settings specific for the SPI interface itself but not for the SPI flash memories).

The registers defined for this block are:

- The QSPI_PID register, which is read only and contains QSPI revision associated information
- The QSPI_CLOCK_CNTRL_REG register, which is used to control external SPI clock (qspi1_sclk)
- The QSPI_DC_REG register used to define the SPI clock mode and chip-select polarity for the four external SPI devices
- The QSPI_CMD_REG register used to control the operation of the SPI command. This register is also used to configure and transfer data.
- Four data registers used for reading the data received and for writing the data to be transferred. These registers are:
  - QSPI_DATA_REG
  - QSPI_DATA_REG_1
  - QSPI_DATA_REG_2
  - QSPI_DATA_REG_3

  These four registers compose a 128-bit shift register.
- The QSPI_STS_REG register, which contains status information

All of these registers can only be written if the QSPI is not busy. This means that they can be written if the QSPI_STS_REG[0] BUSY bit is 0x0. The QSPI becomes busy when a write to the QSPI_CMD_REG[18:16] CMD bit field is performed. Writing to this bit field starts an SPI transaction and sets the QSPI_STS_REG[0] BUSY bit to 0x1. The CMD bit field can be written again when the BUSY bit is 0x0. In addition, the start of the SPI transaction is synchronized to the qspi1_sclk clock and clearing of the BUSY bit is synchronized to the QSPI_FCLK clock.

The register group QSPI_DATA_REG_3, QSPI_DATA_REG_2, QSPI_DATA_REG_1 and QSPI_DATA_REG is treated as a single 128-bit word for shifting data in and out. The QSPI_DATA_REG_3 register is used for the most significant bits and the QSPI_DATA_REG is used for the least significant bits.This applies for both reads and writes. For example, after reading a 128-bit word (WLEN = 0x7F) the most significant bit of the data read, that is bit 127, will be located at QSPI_DATA_REG_3[31] position and the least significant bit, that is bit 0 of the data read, will be located at the QSPI_DATA_REG[0] position.

The data written to this register group should be right justified so that a data pre-shifting is not required. The QSPI_CMD_REG[25:19] WLEN bit field determines the location of the most significant bit and the bit position that will be shifted out first during a write. In order to shift out byte data the WLEN bit field should be set to 0x7 and the data byte should be written to the lower byte of the QSPI_DATA_REG register. By setting the word length to 0x7 the QSPI_DATA_REG register will look like a pseudo 8-bit shift register. When the user wants to write 40-bit long word the WLEN bit field should be set to 0x27, the 32 least significant bits of data should be written to the QSPI_DATA_REG and the rest 8 most significant bits of data should be written to the lower byte of the QSPI_DATA_REG_1 register. By setting WLEN to 0x27 these two registers will look like a pseudo 40-bit shift register. When the word length is greater than 64 bits the QSPI_DATA_REG_2 register is also used and the previously described logic applies. The QSPI_DATA_REG_3 register is used together with the other three data registers when the word length is greater than 96 bits.

When dual or quad read mode is used the number of the words transferred must be even. This number is configured through the QSPI_CMD_REG[11:0] FLEN bit field.

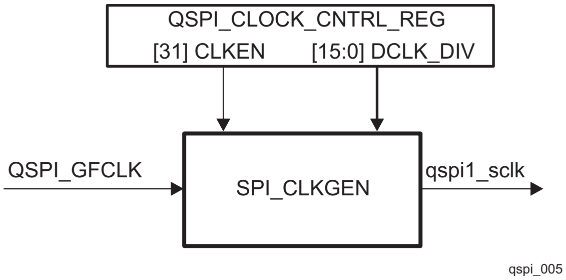
NOTE: The QSPI module does not support a "pass through" mode where the data present on qspi1_d[1] is sent to qspi1_d[0], when 4-pin non-dual read mode is used. This means that setting the QSPI_CMD_REG[18:16] CMD bit field to 0x1 causes the QSPI only to read from an external device using the qspi1_d[1] pad as an input and if a write to the same external device is desired, the CMD bit field should be set to 0x2, which causes the qspi1_d[0] pad to be used as an output.

27.3.1.4 SPI Clock Generator

The SPI clock generator uses the QSPI_FCLK clock as an input, and generates the qspi1_sclk, which is a divided version of the QSPI_FCLK clock. The divide ratio is a 16-bit value configured through the QSPI_CLOCK_CNTRL_REG[15:0] DCLK_DIV bit field and thus provides a division factor in a range from 1 to 65536. The QSPI_FCLK clock is divided by the DCLK_DIV value + 1 to provide the qspi1_sclk clock. When DCLK_DIV = 0x0 the QSPI_FCLK clock equals the DCLK clock. The value in the DCLK_DIV bit field applies only when the QSPI_CLOCK_CNTRL_REG[31] CLKEN bit is set to 0x1. Figure 27-3 shows the SPI_CLKGEN block.

If the CLKEN bit is 0x0 the command specified in the QSPI_CMD_REG[18:16] CMD bit field is not executed and the QSPI_STS_REG[0] BUSY bit is not set. The command is executed only if the CLKEN bit is 0x1 before write to the CMD bit field.

Figure 27-3. SPI_CLKGEN Block



27.3.1.5 SPI Control State-Machine

The SPI control state-machine (SPI_MACHINE) manages the operation of the SPI_CORE block. SPI_MACHINE takes control and configuration information from the registers in the SPI_CNTIF block as input and provides control information to the SPI data shifter. This information is used to control the SPI data port. The SPI_MACHINE also generates status information, which is sent back to the SPI_CNTIF block.

Writing a valid value to the QSPI_CMD_REG[18:16] CMD bit field sets immediately the QSPI_STS_REG[0] BUSY bit to 0x1, activates the corresponding qspi1_cs[n] (n = 0 to 3) and starts the SPI data transaction. The BUSY bit is cleared automatically when QSPI_CMD_REG[25:19] WLEN number of bits are shifted in or out. If the value of the QSPI_STS_REG[27:16] WDCNT bit field is different than 0x0 and WLEN number of bits are shifted already, the SPI_MACHINE waits until another write to the CMD bit field is performed. If the command written to the CMD bit field is valid, then this decrements the value of the WDCNT bit field and starts shfting data in or out again. This is repeated until the WDCNT bit field reaches 0x0, that is, all words of the frame are shifted or till earlier frame termination occurs. While the SPI_MACHINE is waiting for write to the CMD bit field the corresponding qspi1_cs[n] (n = 0 to 3) remains active and the BUSY flag is set to 0x0. In addition, the bit length for each word can be changed during a frame from 1 to 128 bits using the QSPI_CMD_REG[25:19] WLEN bit field.

The SPI_MACHINE also provides a mechanism to terminate the frame earlier. This is done by writing an invalid command to the CMD bit field. An invalid command corresponds to the 0x0 and 0x4 (reserved) values of the CMD bit field. Writing one of these values when the the WDCNT bit field is not equal to 0x0 and when the BUSY flag is 0x0 terminates the frame earlier.

The corresponding qspi1_cs[n] (n = 0 to 3) becomes inactive when all words are shifted or when the frame terminates earlier.

27.3.1.6 SPI Data Shifter

The SPI data shifter handles the capture and generation of the SPI interface signals. Based on control signals from the SPI_MACHINE and SPI_CNTIF blocks, data is shifted in or out on falling or rising edge of qspi1_sclk clock depending on the SPI clock mode selected. Table 27-5 lists the four defined clock modes of operation for the QSPI.

Table 27-5. SPI Clock Modes Definition

Mode	Settings in the QSPI_DC_REG Register		Description
	Value of the CKP bits	Value of the CKPH bits	
0	0	0	Data input captured on rising edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock
1	0	1	Data input captured on falling edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
2	1	0	Data input captured on falling edge of qspi1_sclk clock. Data output generated on rising edge of qspi1_sclk clock
3	1	1	Data input captured on rising edge of qspi1_sclk clock. Data output generated on falling edge of qspi1_sclk clock

27.3.2 QSPI Clock Configuration

The QSPI complies with the PRCM slave-idle protocol. The QSPI_FCLK clock is gated based on the values loaded in the QSPI_SYSCONFIG[3:2] IDLE_MODE bit field. Three modes are supported:

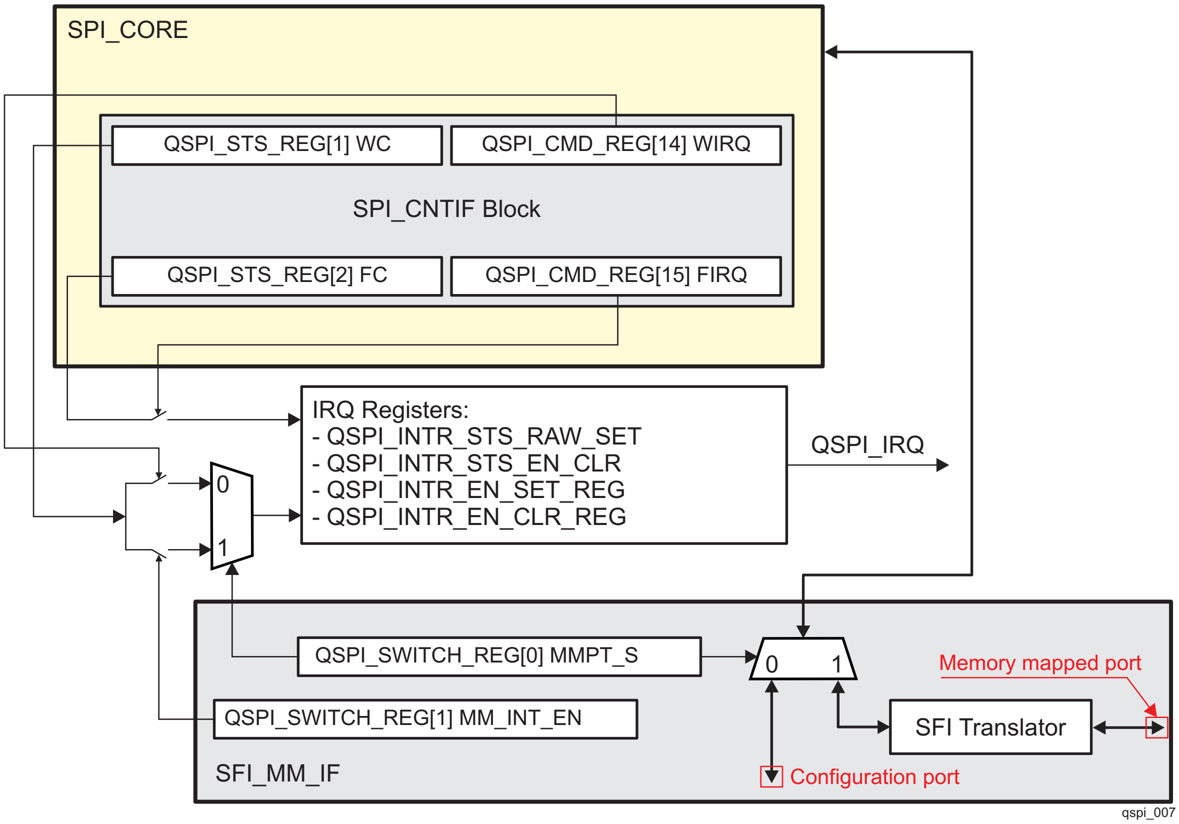
- Force-idle: The QSPI_FCLK clock is gated unconditionally by the QSPI.
- No-idle: The QSPI_FCLK clock is never gated by the QSPI.
- Smart-idle: The QSPI_FCLK clock is gated by the QSPI, depending on its internal requirements.

27.3.3 QSPI Interrupt Requests

The QSPI generates one interrupt request which is connected to the IRQ_CROSSBAR module. This interrupt request, QSPI_IRQ, is connected to the IRQ_CROSSBAR_343 input. The QSPI_IRQ interrupt line can be activated by one of the interrupt events listed in Table 27-6.

Figure 27-4 shows a logical representation of the QSPI interrupt generation scheme.

Figure 27-4. Logical Representation of the QSPI Interrupt Generation Scheme



QSPI_STS_REG[1] WC and QSPI_STS_REG[2] FC are status bits indicating whether word or frame transfer is complete. Setting the corresponding interrupt enable bit (WIRQ or FIRQ) in the QSPI_CMD_REG register allows these events (WC and FC) to generate an interrupt. The WC and FC bits are reset every time the user writes to the QSPI_CMD_REG register or reads the QSPI_STS_REG register. This is done to keep control parameters from changing the interface protocol signals while a transfer is in progress. Additionally, the QSPI_SWITCH_REG[1] MM_INT_EN bit is used to enable or disable the word complete interrupt during operations using the memory-mapped port.

When the QSPI_CMD_REG[14] WIRQ and QSPI_CMD_REG[15] FIRQ bits are set to 0x1 the following applies:

- The QSPI activates its interrupt line only if the interrupts are enabled by setting to 0x1 the corresponding bits in the QSPI_INTR_EN_SET_REG register. These interrupts can be disabled by setting the corresponding bits in the QSPI_INTR_EN_CLR_REG register to 0x1.
- After an interrupt has been serviced, software must clear the corresponding status flag. This is done by

setting the corresponding bit in the QSPI_INTR_STS_EN_CLR register to 0x1, which also clears the corresponding bit in the QSPI_INTR_STS_RAW_SET register. The status flags in the QSPI_INTR_STS_RAW_SET register are set even if the corresponding interrupt is disabled unlike those in the QSPI_INTR_STS_EN_CLR register, which are set only if the corresponding interrupt is enabled.

- The QSPI also generates an interrupt if a certain bit in the QSPI_INTR_STS_RAW_SET register is set to 0x1 and the corresponding interrupt is enabled through the QSPI_INTR_EN_SET_REG register. This feature is useful during user software debugging. In addition, even if interrupts are not enabled a corresponding raw flag in the QSPI_INTR_STS_RAW_SET register is set to 0x1 when an IRQ condition occurs.
- Even if interrupts are not enabled, a certain status bit in the QSPI_INTR_STS_RAW_SET register can also be cleared by setting to 0x1 the corresponding bit in the QSPI_INTR_STS_EN_CLR register.

It must be considered that the previously described scenario applies if the QSPI_CMD_REG[14] WIRQ and QSPI_CMD_REG[15] FIRQ bits are set to 0x1.

NOTE: The QSPI_IRQ interrupt line is activated only if at least one of the following conditions is met:

- The word complete interrupt is enabled:
  - during operations using the memory-mapped port by setting to 0x1 both the QSPI_SWITCH_REG[1] MM_INT_EN and QSPI_INTR_EN_SET_REG[1] WIRQ_ENA_SET bits.
  - during operations using the configuration port by setting to 0x1 both the QSPI_CMD_REG[14] WIRQ and QSPI_INTR_EN_SET_REG[1] WIRQ_ENA_SET bits.
- The frame complete interrupt is enabled setting to 0x1 both the QSPI_CMD_REG[15] FIRQ and QSPI_INTR_EN_SET_REG[0] FIRQ_ENA_SET bits.

The QSPI_IRQ interrupt line is also activated when both the conditions are met.

Table 27-6 lists the event flags and the corresponding mask bits of the sources which can cause interrupts.

Table 27-6. QSPI Events

Event Flag	Event Mask	Description
QSPI_INTR_STS_RAW_SET[1] WIRQ_RAW QSPI_INTR_STS_EN_CLR[1] WIRQ_ENA QSPI_STS_REG[1] WC	QSPI_INTR_EN_SET_REG[1] WIRQ_ENA_SET QSPI_INTR_EN_CLR_REG[1] WIRQ_ENA_CLR QSPI_CMD_REG[14] WIRQ	Word complete interrupt event. Asserted each time after a word is transferred or received.
QSPI_INTR_STS_RAW_SET[0] FIRQ_RAW QSPI_INTR_STS_EN_CLR[0] FIRQ_ENA QSPI_STS_REG[2] FC	QSPI_INTR_EN_SET_REG[0] FIRQ_ENA_SET QSPI_INTR_EN_CLR_REG[0] FIRQ_ENA_CLR QSPI_CMD_REG[15] FIRQ	Frame complete interrupt event. Asserted each time after a frame is transferred or received.

27.3.4 QSPI Memory Regions

Two memory regions are associated with the QSPI. The first memory region is dedicated to the configuration port. Using this memory region, all internal registers can be programmed and serial transfers made from the external SPI device. The L3_Slow start address at which the configuration port is available is 0x4790 0000. The second memory region is associated mainly with the memory-mapped port and is used for communication directly with the external SPI device. This memory region starts at 0x3000 0000 and ends at 0x33FF FFFF L3_Slow address.

It is important to keep in mind that the configuration port provides an access to all the QSPI registers listed in Section 27.4.1. These are configuration registers and also four data registers. The configuration registers are used to configure typical SPI and serial flash memory settings and the four data registers are used for read and write operations. When communicating with an external SPI device (but not an SPI flash memory), the SPI_CORE module should be used and the data exchanged is available through these four data registers, which can be accessed only through the configuration port. When a communication with an external SPI flash memory is desired, the memory-mapped port should be used.

In other words, to read from an external SPI flash memory, first configure the QSPI through the configuration port and then perform a read through the memory-mapped port.

27.4 QSPI Registers

27.4.1 QSPI Registers

Table 27-7 lists the memory-mapped registers for the QSPI. All register offset addresses not listed in Table 27-7 should be considered as reserved locations and the register contents should not be modified.

Table 27-7. QSPI Registers

Offset	Acronym	Register Name	Section
0h	QSPI_PID		Section 27.4.1.1
10h	QSPI_SYSCONFIG		Section 27.4.1.2

27.4.1.8 QSPI_CLOCK_CNTRL_REG Register (offset = 40h) [reset = 0h]

QSPI_CLOCK_CNTRL_REG is shown in Figure 27-12 and described in Table 27-15.

SPI Clock Control (SPICC) Register. SPICC controls the SPI clock generation. The SPICC controls the SPI clock generation. The input for clock division is the input SPI_CLK signal. The output clock will be divided by DCLK_DIV+1 to provide the output SPI interface clock as well as controlling the main portion of the design. Note that loading a value or 0 input DCLK_DIV will force the input SPI_CLK to be used directly for the SPI interface clock. The value in DCLK_DIV is only loaded when CLKEN transitions from a 0 to 1 state. This register can only be written to when the SPI is not busy, as defined by SPISR[0].

27.4.1.9 QSPI_DC_REG Register (offset = 44h) [reset = 0h]

QSPI_DC_REG is shown in Figure 27-13 and described in Table 27-16.

SPI Device Control (SPIDC) Register. The SPIDC controls the different modes for each output chip select. The SPIDC controls the different modes for each output chip select. NOTE: The combination of [CKPn, CKPHn] creates the SPI mode . Most serial Flash devices only support SPI modes 0 and 3. SPI devices transmit and receive data on opposite edge s of the SPI clock. Note that changing the clock polarity also swaps the transmit/receive clock edge relationship. If a slave device states that it receives data on the rising edge and transmits on the falling edge of the clock, then it can only support mode 0 or 3 (CKPn = 0, CKPHn = 0 OR CKPn = 1, CKPHn = 1). This register can only be written to when the SPI is not busy, as defined by SPISR[0].

27.4.1.10 QSPI_CMD_REG Register (offset = 48h) [reset = 0h]

QSPI_CMD_REG is shown in Figure 27-14 and described in Table 27-17.

SPI Command Register (SPICR). Sets up the SPI command. Since the SPI convention is to always shift in new data (LSB position) while shifting out data from the MSB position the 'read', 'write' and 'read dual' commands actually just initiate a transfer. Write commands will assert the spi_dout_oe_n signal to enable the tristate buffer for spi_dout_o. Read commands will deassert the spi_dout_oe_n signal to disable the tristate buffer for spi_dout_o. Executing any of these commands will initiate the next word transfer (except for the case of "read dual"). The 'read dual' command will also initiate a transfer like read or write. However, this command is used to communicate with serial Flash devices which support dual read output. Dual read output mode uses the spi_dout signal as an input along with the spi_din input (spi_dout is therefore a bidirectional signal). WLEN transfers must be even. The spi_din input will contain the odd number bytes and the spi_dout bidirectional/input will contain the even number bytes. This read mode effectively doubles the read bandwidth of the design. This command can only be used on those devices which support a dual read command.

The 'read quad' command is similar to the read dual command, except it uses a 6 pin interface. The

In particular, transfers are started by writing to byte 2 of this register (only byte 2 will start a transfer). Writing a "reserved" value to the CMD register will terminate the frame transfer. This can be used to abort a frame if desired. Reserved commands are CMD = 00 and CMD_MODE=1 AND CMD=11.

This register can only be written to when the SPI is not busy, as defined by SPISR[0]. If the SPI clock has not been enabled (SPICC[31] = 0), then writing to this register will NOT start the SPI transfer. The transfer will not be queued to start upon the activation of the clock. The transfer will ONLY start if SPICC[31] = 1 when this register is written.

14	WIRQ	R/W	0h	Word count interrupt enable. 0h (R/W) = Disable. 1h (R/W) = Enable.
13-12	RSVD	R	0h	Reserved
11-0	FLEN	R/W	0h	Frame Length. 0h (R/W) = 1 word. 1h (R/W) = 2 words. FFFh (R/W) = 4096 words.

27.4.1.11 QSPI_STS_REG Register (offset = 4Ch) [reset = 0h]

QSPI_STS_REG is shown in Figure 27-15 and described in Table 27-18.

SPI Status Register (SPISR). The SPI Status Register contains indicators to allow the user to monitor the progression of a frame transfer. The SPI Status Register contains indicators to allow the user to monitor the progression of a frame transfer. The word complete (WC) and frame complete (FC) bits are used as stimulus for generating interrupts. Setting the corresponding interrupt enable bit in the SPI Command Register will allow these events to generate an interrupt. The WDCNT field will reset itself when transitioning from the LOAD state to the SHIFT state. THE WC and FC fields will be reset every time the user writes to the SPI Command Register or the SPI Status Register is read.
The BUSY bit of this register (SPISR[0]) is used to block write access to the SPICC, SPIDC, SPICR and SPIDR registers. This is done to keep control parameters from changing the interface protocol signals while a transfer is in progress. If a write is made while BUSY is active, the write will simply not occur. BUSY is set immediately when SPICR[18:16] are written and BUSY will be cleared when the current word has completed transfer (on SPISR[1]). However, if the SPI clock enable is not set (SPICC[31] = 0) and a command is executed (SPICR[18:16] is written to start a command), BUSY will NOT be set and the command will not be executed. BUSY will ONLY go high if SPICC[31] = 1 and SPICR[18:16] is written.

Table 27-18. QSPI_STS_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	RSVD_2	R	0h	
27-16	WDCNT	R/W	0h	Word count. This field will reflect the 1 to 4096 words transferred
15-3	RSVD	R	0h	
2	FC	R/W	0h	Frame complete. This bit is set after all of the requested words have been transmitted. 0h (R/W) = Transfer is not complete. 1h (R/W) = Transfer is complete. This bit is reset when the SPI Status Register is read.
1	WC	R/W	0h	Word complete. This bit is set after each word transfer is completed. 0h (R/W) = Word transfer is not complete. 1h (R/W) = Word transfer is complete. This bit is reset when the SPI Status Register is read.
0	BUSY	R/W	0h	Busy bit. Active transfer in progress. This bit is only set during an active word transfer. Between words, the bit will clear to signal that it is ok to read/write the data registers. 0h (R/W) = Idle. 1h (R/W) = Busy.

27.4.1.12 QSPI_DATA_REG Register (offset = 50h) [reset = 0h]

QSPI_DATA_REG is shown in Figure 27-16 and described in Table 27-19.

SPI Data Register (SPIDR). Data received in the data register is shifted into the LSB position and the contents of the register are shifted to the left. The register is cleared between reads or writes. Data received in the data register is shifted into the LSB position and the contents of the register are shifted to the left. The register is cleared between reads or writes.
When writing data to the register it should be right justified so pre-shifting is not required. The word length field will determine the location of the most significant bit and the bit position that will be shifted out first during a write. In order to shift out byte data the word length should be set to 7 and the data byte should be written to the lower byte of the data register. By setting the word length to 7 the data register will look like a pseudo 8-bit shift register. The word length setting does not affect the VBUSP read or write operations.
This register can only be written to when the SPI is not busy, as defined by SPISR[0].

Chapter 28

General-Purpose Input/Output

This chapter describes the GPIO of the device.

Topic **Page**

28.1 Introduction

28.1.1 Purpose of the Peripheral

The general-purpose interface combines six general-purpose input/output (GPIO) modules. Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 192 (6 × 32) pins. These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.
- Wake-up request generation in idle mode upon the detection of external events.

28.1.2 GPIO Features

Each GPIO module is made up of 32 identical channels. Each channel can be configured to be used in the following applications:

- Data input/output
- Keyboard interface with a de-bouncing cell
- Synchronous interrupt generation (in active mode) upon the detection of external events (signal transition(s) and/or signal level(s))
- Wake-up request generation (in Idle mode) upon the detection of signal transition(s)

Global features of the GPIO interface are:

- Synchronous interrupt requests from each channel are processed by two identical interrupt generation sub-modules to be used independently by the ARM Subsystem
- Wake-up requests from input channels are merged together to issue one wake-up signal to the system
- Shared registers can be accessed through “Set & Clear” protocol

28.1.3 Unsupported GPIO Features

The wake-up feature of the GPIO modules is only supported on GPIO0.

28.2 Integration

The device instantiates six GPIO_V2 modules. Each GPIO module provides the support for 32 dedicated pins with input and output configuration capabilities. Input signals can be used to generate interruptions and wake-up signal. Two Interrupt lines are available for bi-processor operation. Pins can be dedicated to be used as a keyboard controller.

With six GPIO modules, the device allows for a maximum of 192 GPIO pins. (The exact number available varies as a function of the device configuration and pin muxing.) GPIO0 is in the Wakeup domain and may be used to wakeup the device via external sources. GPIO[1:5] are located in the peripheral domain.

Figure 28-1 and Figure 28-2 show the GPIO integration.

Figure 28-1. GPIO0 Module Integration

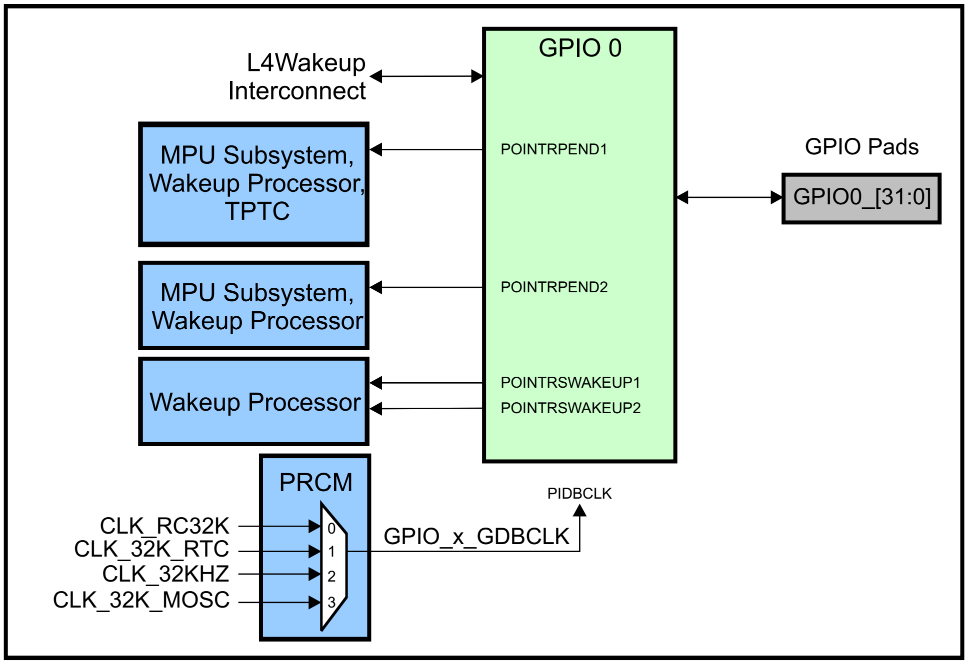

Figure 28-2. GPIO[1–5] Module Integration

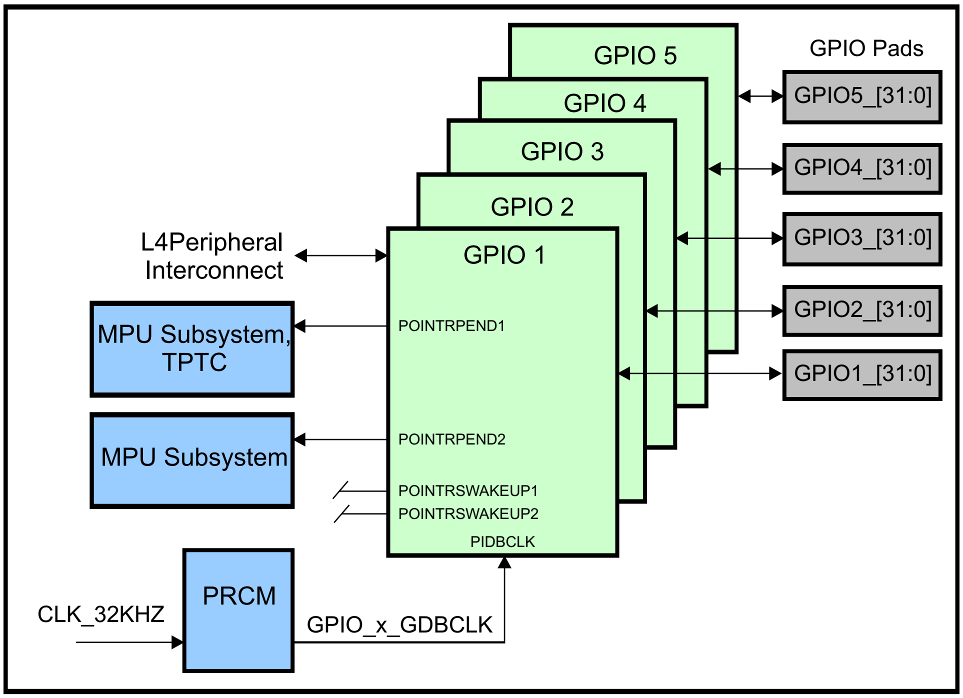


28.2.1 GPIO Connectivity Attributes

The general connectivity attributes for the GPIO modules in the device are shown in Table 28-1 and Table 28-2.

Table 28-1. GPIO0 Connectivity Attributes

Attributes	Type
Power Domain	Wakeup Domain
Clock Domain	PD_WKUP_L4_WKUP_GCLK (OCP) GPIO_0_GDBCLK (Debounce)
Reset Signals	WKUP_DOM_RST_N
Idle/Wakeup Signals	Smart Idle / Slave Wakeup
Interrupt Requests	Two Interrupts: INTRPEND1 (GPIOINT0A) to MPU subsystem and Wakeup Processor INTRPEND2 (GPIOINT0B) to MPU subsystem and Wakeup Processor Two wakeups to Wakeup Processor: WAKEUP1 and WAKEUP2
DMA Requests	Interrupt Requests are redirected as DMA requests: 1 DMA request (GPIOEVT0)
Physical Address	L4 Wakeup slave port

Table 28-2. GPIO[1:5] Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK (OCP) GPIO_1_GDBCLK (GPIO1 Debounce) GPIO_2_GDBCLK (GPIO2 Debounce) GPIO_3_GDBCLK (GPIO3 Debounce) GPIO_4_GDBCLK (GPIO4 Debounce) GPIO_5_GDBCLK (GPIO5 Debounce)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	Two Interrupts: INTRPEND1 (GPIOINTxA) to MPU subsystem INTRPEND2 (GPIOINTxB) to MPU subsystem
DMA Requests	Interrupt Requests are redirected as DMA requests: 1 DMA request per instance (GPIOEVTx)
Physical Address	L4 Peripheral slave port

28.2.2 GPIO Clock and Reset Management

The GPIO modules require two clocks: The de-bounce clock is used for the de-bouncing cells. The interface clock provided by the peripheral bus (L4 interface) is also the functional clock and is used through the entire GPIO module (except within the de-bouncing sub-module). It clocks the OCP interface and the internal logic. For GPIO0 the debounce clock is selected from one of the following sources using the CLKSEL_GPIO0_DBCLK register in the PRCM:

- The on-chip ~32.768 kHz oscillator (CLK_RC32K)
- The PER PLL generated 32.768 kHz clock (CLK_32KHZ)
- The external 32.768 kHz oscillator/clock for the RTC module (CLK_32K_RTC)
- The divided down 32.768 kHz oscillator/clock from the master oscillator (CLK_32K_MOSC)

Table 28-3. GPIO Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
GPIO0			
Functional / Interface clock	26 MHz	CLK_M_OSC	pd_wkup_l4_wkup_gclk From PRCM
Debounce Functional clock	32.768 KHz	CLK_RC32K CLK_32KHZ (PER_CLKOUTM2 / 5859.375) CLK_32K_RTC CLK_32K_MOSC (CLK_M_OSC divide down)	pd_wkup_gpio0_gdbclk From PRCM
GPIO[1:5]			
Functional / Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk From PRCM
Debounce Functional clock (GPIO1)	32.768 KHz	CLK_32KHZ (PER_CLKOUTM2 / 5859.375)	pd_per_gpio_1_gdbclk From PRCM
Debounce Functional clock (GPIO2)	32.768 KHz	CLK_32KHZ (PER_CLKOUTM2 / 5859.375)	pd_per_gpio_2_gdbclk From PRCM
Debounce Functional clock (GPIO3)	32.768 KHz	CLK_32KHZ (PER_CLKOUTM2 / 5859.375)	pd_per_gpio_3_gdbclk From PRCM
Debounce Functional clock (GPIO4)	32.768 KHz	CLK_32KHZ (PER_CLKOUTM2 / 5859.375)	pd_per_gpio_4_gdbclk From PRCM
Debounce Functional clock (GPIO5)	32.768 KHz	CLK_32KHZ (PER_CLKOUTM2 / 5859.375)	pd_per_gpio_5_gdbclk From PRCM

28.2.3 GPIO Pin List

Each GPIO module includes 32 interface I/Os. These signals are designated as shown in Table 28-4. Note that for this device, most of these signals will be multiplexed with functional signals from other interfaces.

Table 28-4. GPIO Pin List

Pin	Type	Description
GPIO0_[31:0]	I/O	General-purpose input and output pins
GPIO1_[31:0]		
GPIO2_[31:0]		
GPIO3_[31:0]		
GPIO4_[31:0]		
GPIO5_[31:0]		

28.3 Functional Description

This section discusses the operational details and basic functions of the GPIO peripheral.

28.3.1 Operating Modes

Four operating modes are defined for the module:

- **Active mode:** the module is running synchronously on the interface clock, interrupt can be generated according to the configuration and the external signals.
- **Idle mode:** the module is in a waiting state, interface clock can be stopped , no interrupt can be generated, a wake-up signal can be generated according to the configuration and external signals. If the debouncing clock is active, the debouncing cell can be used to sample and to filter the input to generate a wakeup event.
- **Inactive mode:** the module has no activity, interface clock can be stopped, no interrupt can be generated, and the wake-up feature is inhibited.
- **Disabled mode:** the module is not used, internal clock paths are gated, no interrupt or wake-up request can be generated.

The Idle and Inactive modes are configured within the module and activated on request by the host processor through system interface sideband signals. The Disabled mode is set by software through a dedicated configuration bit. It unconditionally gates the internal clock paths not use for the system interface. All module registers are 8, 16 or 32-bit accessible through the OCP compatible interface (little endian encoding). In active mode, the event detection (level or transition) is performed in the GPIO module using the interface clock. The detection's precision is set by the frequency of this clock and the selected internal gating scheme.

28.3.2 Clocking and Reset Strategy

28.3.2.1 Clocks

GPIO module runs using two clocks:

- The debouncing clock is used for the debouncing sub-module logic (without the corresponding configuration registers). This module can sample the input line and filters the input level using a programmed delay.
- The interface clock provided by the peripheral bus (OCP compatible system interface). It is used through the entire GPIO module (except within the debouncing sub-module logic). It clocks the OCP interface and the internal logic. Clock gating features allow adapting the module power consumption to the activity.

28.3.2.2 Clocks, Gating and Active Edge Definitions

The interface clock provided by the peripheral bus (OCP compatible system interface) is used through the entire GPIO module. Two clock domains are defined: the OCP interface and the internal logic. Each clock domain can be controlled independently. Sampling operations for the data capture and for the events detection are done using the rising edge. The data loaded in the data output register (GPIO_DATAOUT) is set at the output GPIO pins synchronously with the rising edge of the interface clock.

Five clock gating features are available:

- Clock for the system interface logic can be gated when the module is not accessed, if the AUTOIDLE configuration bit in the system configuration register (GPIO_SYSCONFIG) is set. Otherwise, this logic is free running on the interface clock.
- Clock for the input data sample logic can be gated when the data in register is not accessed.
- Four clock groups are used for the logic in the synchronous events detection. Each 8 input GPIO_V2 pins group will have a separate enable signal depending on the edge/level detection register setting. If a group requires no detection, then the corresponding clock will be gated. All channels are also gated using a 'one out of N' scheme. N can take the values 1, 2, 4 or 8. The interface clock is enabled for this logic one cycle every N cycles. When N is equal to 1, there is no gating and this logic is free running on the interface clock. When N is between 2 to 8, this logic is running at the equivalent

frequency of interface clock frequency divided by N.
- In Inactive mode, all internal clock paths are gated.
- In Disabled mode, all internal clock paths not used for the system interface are gated. All GPIO registers are accessible synchronously with the interface clock.

28.3.2.3 Sleep Mode Request and Acknowledge

Upon a Sleep mode request issued by the host processor, the GPIO module goes to the Idle mode according to the IDLEMODE field in the system configuration register (GPIO_SYSCONFIG).

- IDLEMODE = 0 (Force-Idle mode): the GPIO goes in Inactive mode independently of the internal module state and the Idle acknowledge is unconditionally sent. In Force-Idle mode, the module is in Inactive mode and its wake-up feature is totally inhibited.
- IDLEMODE = 1h (No-Idle mode): the GPIO does not go to the Idle mode and the Idle acknowledge is never sent.
- IDLEMODE = 2h (Smart-Idle mode) or IDLEMODE = 3h (Smart-Idle mode): the GPIO module evaluates its internal capability to have the interface clock switched off. Once there is no more internal activity (the data input register completed to capture the input GPIO pins, there is no pending interrupt, all interrupt status bits are cleared, and there is no write access to GPIO_DEBOUNCINGTIME register pending to be synchronized), the Idle acknowledge is asserted and the GPIO enters Idle mode, ready to issue a wake-up request when the expected transition occurs on an enabled GPIO input pin. This wake-up request is effectively sent only if the ENAWAKEUP bit in GPIO_SYSCONFIG is set to enable the GPIO wakeup capability. When the system is awake, the Idle Request goes inactive, the Idle acknowledge and wake-up request (if it is the GPIO that triggered the system’s wakeup) signals are immediately de-asserted, and the asynchronous wake-up request (if existing) is reflected into the synchronous interrupt status registers.

NOTE: Idle mode request and Idle acknowledge are system interface sideband signals. Once the GPIO acknowledges the Sleep mode request (Idle acknowledge has been sent), the interface clock can be stopped anytime.

Upon a Sleep mode request issued by the host processor, the GPIO module goes to the Idle mode only if there is no active bit in GPIO_IRQSTS_RAW_n registers.

28.3.2.4 Reset

The OCP hardware Reset signal has a global reset action on the GPIO. All configuration registers, all DFFs clocked with the Interface clock or Debouncing clock and all internal state machines are reset when the OCP hardware Reset is active (low level). The RESETDONE bit in the system status register (GPIO_SYSSTS) monitors the internal reset status: it is set when the Reset is completed on both OCP and Debouncing clock domains. The software Reset (SOFTRESET bit in the system configuration register) has the same effect as the OCP hardware Reset signal, and the RESETDONE bit in GPIO_SYSSTS is updated in the same condition.

28.3.3 Interrupt and Wake-up Features

28.3.3.1 Functional Description

In order to generate an interrupt request to a host processor upon a defined event (level or logic transition) occurring on a GPIO pin, the GPIO configuration registers have to be programmed as follows:

- Interrupts for the GPIO channel must be enabled in the GPIO_IRQSTS_SET_0 and/or GPIO_IRQSTS_SET_1 registers.
- The expected event(s) on input GPIO to trigger the interrupt request has to be selected in the GPIO_LEVELDETECT0, GPIO_LEVELDETECT1, GPIO_RISINGDETECT, and GPIO_FALLINGDETECT registers.

In order to generate a wake-up request to a host processor upon a defined event (logic transition) occurring on a GPIO pin, the GPIO configuration registers have to be programmed as follows:

- The GPIO channel must be enabled in the GPIO_IRQWAKEN register.
- The expected event(s) on input GPIO to trigger the interrupt (or the wake-up) request has to be selected in the GPIO_RISINGDETECT and GPIO_FALLINGDETECT registers. Wake-up request can only be generated on rising and/or on falling transitions.

For instance, interrupt generation on both edges on input k is configured by setting to 1 the *k*th bit in registers GPIO_RISINGDETECT and GPIO_FALLINGDETECT along with the interrupt enabling for one or both interrupt lines (GPIO_IRQSTS_SET_n).

NOTE: All interrupt (or wake-up) sources (the 32 input GPIO channels) are merged together to issue two synchronous interrupt requests 1 and 2, and two asynchronous wake-up requests.

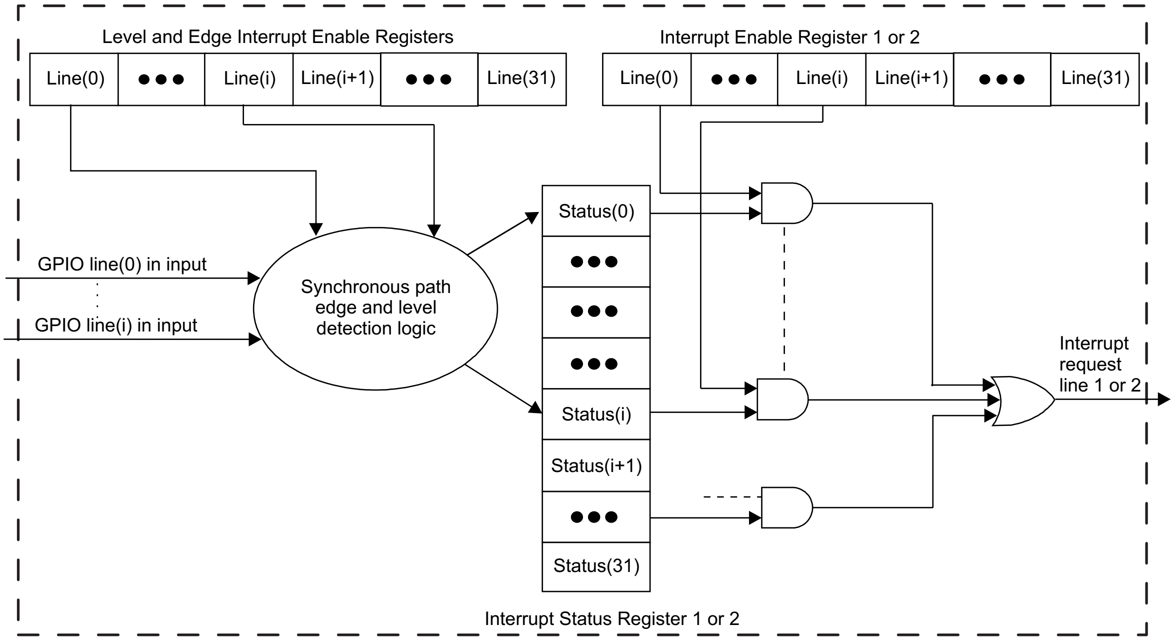
28.3.3.2 Synchronous Path: Interrupt Request Generation

In Active mode, once the GPIO configuration registers have been set to enable the interrupt generation, a synchronous path (Figure 28-3) samples the transitions and levels on the input GPIO with the internally gated interface clock. When an event matches the programmed settings, the corresponding bit in the GPIO_IRQSTS_RAW_n registers is set to 1 and, on the following interface clock cycle, the interrupt lines 1 and/or 2 are activated (depending on the GPIO_IRQSTS_SET_n registers).

Due to the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (the internally gated interface clock period is equal to N times the interface clock period). This minimum pulse width has to be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

As the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This should not exceed 3 internally gated interface clock cycles + 2 interface clock cycles when the debouncing feature is not used. When the debouncing feature is active, the latency depends on the GPIO_DEBOUNCINGTIME register value and should be less than 3 internally gated interface clock cycles + 2 interface clock cycles + GPIO_DEBOUNCINGTIME value debouncing clock cycles + 3 debouncing clock cycles.

Figure 28-3. Interrupt Request Generation



GPIO0–5

28.3.3.3 Asynchronous Path: Wake-up Request Generation

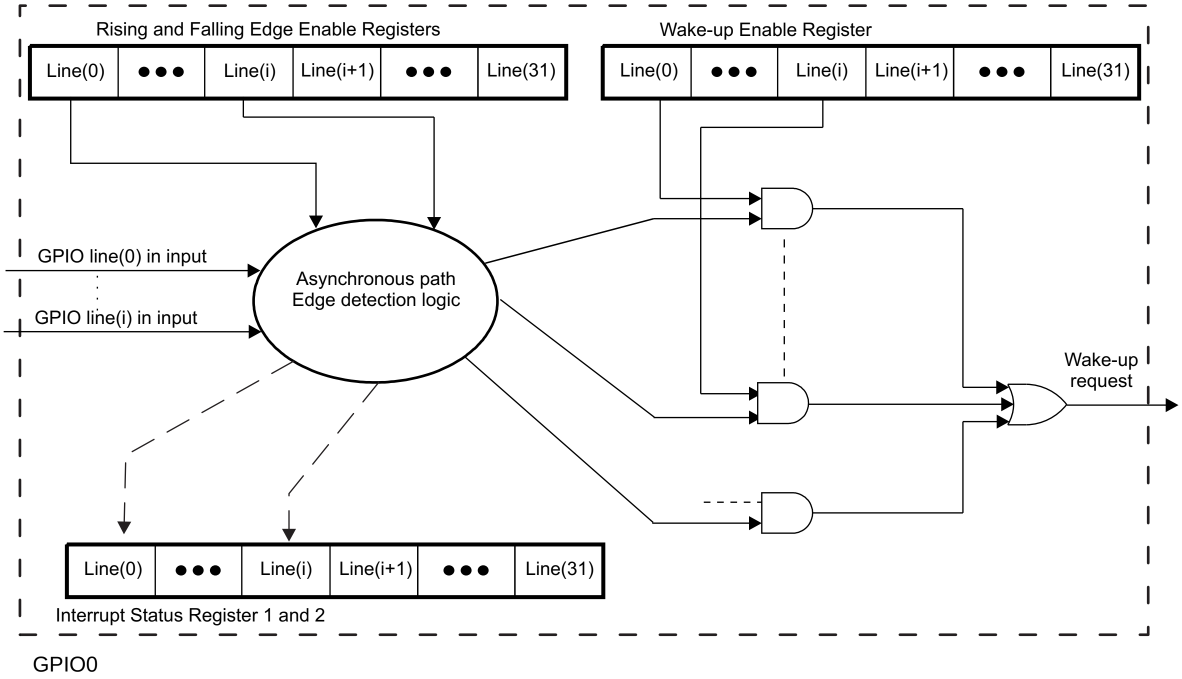
In Idle mode (interface clock is shut down, the GPIO configuration registers have been previously programmed), an asynchronous path (Figure 28-4) detects the expected transition(s) on input GPIO (according to the registers programming) and activates an asynchronous wake-up request if the wakeup enable register is set. There is only one external wake-up line, since all wake-up sources are merged together. Once the system is in wake up, the interface clock is re-started and, according to the input GPIO pin that triggered the wake-up request, the corresponding bits in the GPIO_IRQSTS_RAW_n registers are synchronously set to 1; on the following internal clock cycle, the interrupt lines 1 and/or 2 are active (active high) when the corresponding bits in GPIO_IRQSTS_SET_n registers are set.

NOTE: If debouncing is not enabled, there is no minimum input pulse width to trigger the wake-up request since there is no sampling operation.

If debouncing is used, the minimum pulse width is set by the debouncing specified time.

The ENAWAKEUP bit in the system configuration register (GPIO_SYSCONFIG) enables or disables the GPIO wake-up feature globally: if this bit is 0, the GPIO_IRQWAKEN has no effect.

Figure 28-4. Wake-Up Request Generation



28.3.3.4 Interrupt (or Wake-up) Line Release

When the host processor receives an interrupt request issued by the GPIO module, it can read the corresponding GPIO_IRQSTS_n register to find out which input GPIO has triggered the interrupt (or the wake-up request). After servicing the interrupt (or acknowledging the wake-up request), the processor resets the status bit and releases the interrupt line by writing a 1 in the corresponding bit of the GPIO_IRQSTS_n register. If there is still a pending interrupt request to serve (all bits in the GPIO_IRQSTS_RAW_n register not masked by the GPIO_IRQSTS_SET_n, which are not cleared by setting the GPIO_IRQSTS_CLR_n), the interrupt line will be re-asserted.

28.3.4 General-Purpose Interface Basic Programming Model

28.3.4.1 Power Saving by Grouping the Edge/Level Detection

Each GPIO module implements four gated clocks used by the edge/level detection logic to save power. Each group of eight input GPIO pins generates a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no edge/level detection, then the corresponding clock is gated (cut off). Grouping the edge/level enable can save the power consumption of the module as described in the following example.

If any of the registers:

- GPIO_LEVELDETECT0
- GPIO_LEVELDETECT1
- GPIO_RISINGDETECT
- GPIO_FALLINGDETECT

are set to 0101 0101h, then all clocks are active (power consumption is high);

are set to 0000 00FFh, then a single clock is active.

NOTE: When the clocks are enabled by writing to the GPIO_LEVELDETECT0, GPIO_LEVELDETECT1, GPIO_RISINGDETECT, and GPIO_FALLINGDETECT registers, the detection starts after 5 clock cycles. This period is required to clean the synchronization edge/level detection pipeline.

The mechanism is independent of each clock group. If the clock has been started before a new setting is performed, the following is recommended: first, set the new detection required; second, disable the previous setting (if necessary). In this way, the corresponding clock is not gated and the detection starts immediately.

28.3.4.2 Set and Clear Instructions

The GPIO module implements the set-and-clear protocol register update for the data output and interrupt enable, and wake-up enable registers. This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s).

Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear (recommended): Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing a 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

28.3.4.2.1 Clear Instruction

28.3.4.2.1.1 Clear Interrupt Enable Registers (GPIO_IRQSTS_CLR_0 and GPIO_IRQSTS_CLR_1):

- A write operation in the clear interrupt enable1 (or enable2) register clears the corresponding bit in the interrupt enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.
- A read of the clear interrupt enable1 (or enable2) register returns the value of the interrupt enable1 (or enable2) register.

28.3.4.2.1.2 Clear Wake-up Enable Register (GPIO_CLRWKUENA):

- A write operation in the clear wake-up enable register clears the corresponding bit in the wake-up enable register when the written bit is 1; a written bit at 0 has no effect.
- A read of the clear wake-up enable register returns the value of the wake-up enable register.

28.3.4.2.1.3 Clear Data Output Register (GPIO_CLRDATAOUT):

- A write operation in the clear data output register clears the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.
- A read of the clear data output register returns the value of the data output register.

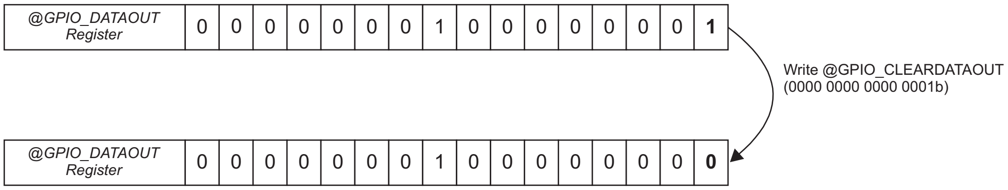
28.3.4.2.1.4 Clear Instruction Example

Assume the data output register (or one of the interrupt/wake-up enable registers) contains the binary value, 0000 0001 0000 0001h, and you want to clear bit 0.

With the clear instruction feature, write 0000 0000 0000 0001h at the address of the clear data output register (or at the address of the clear interrupt/wake-up enable register). After this write operation, a reading of the data output register (or the interrupt/wake-up enable register) returns 0000 0001 0000 0000h; bit 0 is cleared.

NOTE: Although the general-purpose interface registers are 32-bits wide, only the 16 least-significant bits are represented in this example.

Figure 28-5. Write @ GPIO_CLRDATAOUT Register Example



28.3.4.2.2 Set Instruction

28.3.4.2.2.1 Set Interrupt Enable Registers (GPIO_IRQSTS_SET_0 and GPIO_IRQSTS_SET_1):

- A write operation in the set interrupt enable1 (or enable2) register sets the corresponding bit in the interrupt enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.
- A read of the set interrupt enable1 (or enable2) register returns the value of the interrupt enable1 (or enable2) register.

28.3.4.2.2.2 Set Wake-up Enable Register (GPIO_SETWKUENA):

- A write operation in the set wake-up enable register sets the corresponding bit in the wake-up enable register when the written bit is 1; a written bit at 0 has no effect.
- A read of the set wake-up enable register returns the value of the wake-up enable register.

28.3.4.2.2.3 Set Data Output Register (GPIO_SETDATAOUT):

- A write operation in the set data output register sets the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.
- A read of the set data output register returns the value of the data output register.

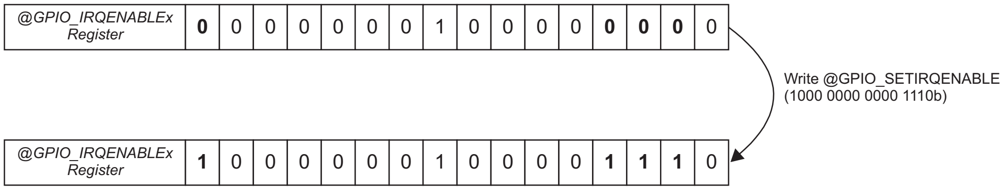
28.3.4.2.2.4 *Set Instruction Example*

Assume the interrupt enable1 (or enable2) register (or the data output register) contains the binary value, 0000 0001 0000 0000h, and you want to set bits 15, 3, 2, and 1.

With the set instruction feature, write 1000 0000 0000 1110h at the address of the set interrupt enable1 (or enable2) register (or at the address of the set data output register). After this write operation, a reading of the interrupt enable1 (or enable2) register (or the data output register) returns 1000 0001 0000 1110h; bits 15, 3, 2, and 1 are set.

NOTE: Although the general-purpose interface registers are 32-bits wide, only the 16 least-significant bits are represented in this example.

Figure 28-6. Write @ GPIO_SETIRQENx Register Example



28.3.4.3 Data Input (Capture)/Output (Drive)

The output enable register (GPIO_OE) controls the output/input capability for each pin. At reset, all the GPIO-related pins are configured as input and output capabilities are disabled. This register is not used within the module; its only function is to carry the pads configuration.

When configured as an output (the desired bit reset in GPIO_OE), the value of the corresponding bit in the GPIO_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set and clear protocol register update feature. This feature lets you set or clear specific bits of this register with a single write access to the set data output register (GPIO_SETDATAOUT) or to the clear data output register (GPIO_CLRDATAOUT) address. If the application uses a pin as an output and does not want interrupt/wake-up generation from this pin, the application must properly configure the wake-up enable and the interrupt enable registers.

When configured as an input (the desired bit set to 1 in GPIO_OE), the state of the input can be read from the corresponding bit in the GPIO_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock. When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and to write data). If the application uses a pin as an input, the application must properly configure the wake-up enable and the interrupt enable registers to the interrupt and wake-up feature as needed.

28.3.4.4 Debouncing Time

To enable the debounce feature for a pin, the GPIO configuration registers must be programmed as follows:

- The GPIO pin must be configured as input in the output enable register (write 1 to the corresponding bit of the GPIO_OE register).
- The debouncing time must be set in the debouncing value register (GPIO_DEBOUNCINGTIME). The GPIO_DEBOUNCINGTIME register is used to set the debouncing time for all input lines in the GPIO module. The value is global for all the ports of one GPIO module, so up to six different debouncing values are possible. The debounce cell is running with the debounce clock (32 kHz). This register represents the number of the clock cycle(s) (one cycle is 31 microseconds long) to be used.

  The following formula describes the required input stable time to be propagated to the debounced output:

Debouncing time = (DEBOUNCETIME + 1) × 31 µs

Where the DEBOUNCETIME field value in the GPIO_DEBOUNCINGTIME register is from 0 to 255.

- The debouncing feature must be enabled in the debouncing enable register (write 1 to the corresponding DEBOUNCEEN bit in the GPIO_DEBOUNCEN register).

28.3.4.5 GPIO as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface (Figure 28-7). You can dedicate channels based on the keyboard matrix = * c). Figure 28-7 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pull-up. Column channels are configured as outputs and drive a low level.

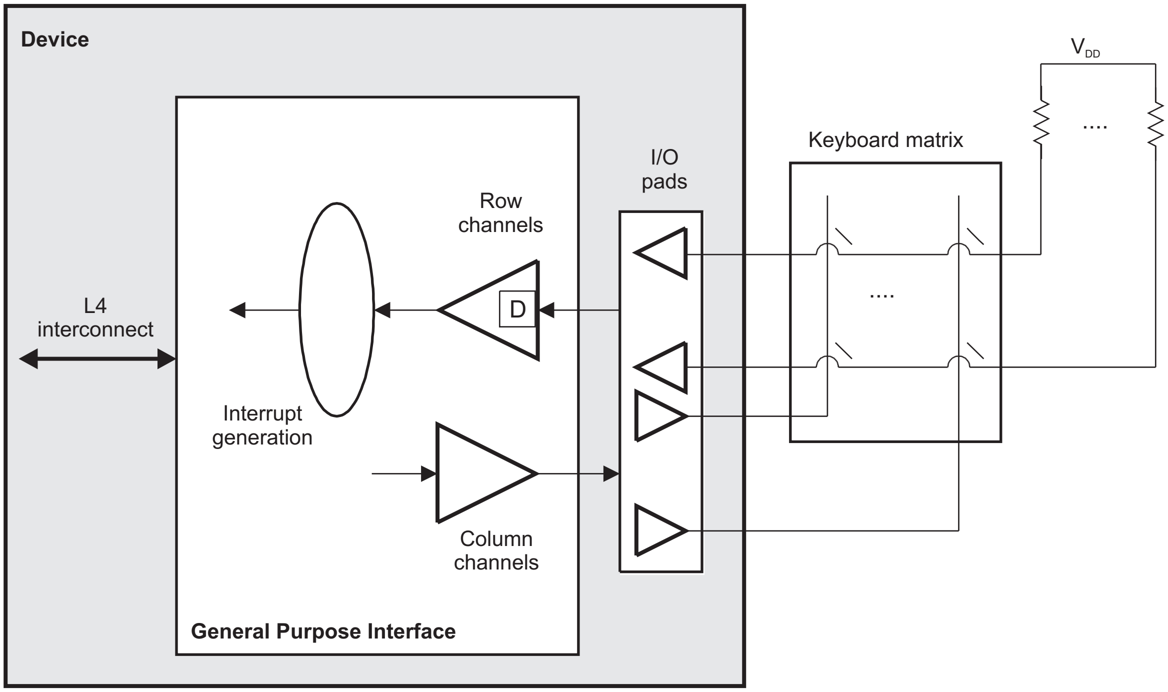
When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see Section 28.3.3).

When the keyboard interrupt is received, the processor can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

Figure 28-7. General-Purpose Interface Used as a Keyboard Interface



28.4 GPIO Registers

28.4.1 GPIO Registers

Table 28-5 lists the memory-mapped registers for the GPIO. All register offset addresses not listed in Table 28-5 should be considered as reserved locations and the register contents should not be modified.

Table 28-5. GPIO REGISTERS

Offset	Acronym	Register Name	Section

28.4.1.1 GPIO_REVISION Register (offset = 0h) [reset = 50600801h]

Register mask: FFFFFFFFh

GPIO_REVISION is shown in Figure 28-8 and described in Table 28-6.

The GPIO revision register is a read only register containing the revision number of the GPIO module. A write to this register has no effect, the same as the reset.

Figure 28-8. GPIO_REVISION Register

5-0	MINOR	R	1h	Minor Revision

28.4.1.2 GPIO_SYSCONFIG Register (offset = 10h) [reset = 0h]

Register mask: FFFFFFFFh

GPIO_SYSCONFIG is shown in Figure 28-9 and described in Table 28-7.

The GPIO_SYSCONFIG register controls the various parameters of the L4 interconnect. When the AUTOIDLE bit is set, the GPIO_DATAIN read command has a 3 OCP cycle latency due to the data in sample gating mechanism. When the AUTOIDLE bit is not set, the GPIO_DATAIN read command has a 2 OCP cycle latency.

4-3	IDLEMODE	R/W	0h	Power Management, Req/Ack control. 0h (R/W) = Force-idle. An idle request is acknowledged unconditionally. 1h (R/W) = No-idle. An idle request is never acknowledged 2h (R/W) = Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module 3h (R/W) = Smart Idle Wakeup (GPIO0 only)
2	ENAWAKEUP	R/W	0h	Wakeup control. 0h (R/W) = Wakeup generation is disabled. 1h (R/W) = Wakeup capability is enabled upon expected transition on input GPIO pin
1	SOFTRESET	R/W	0h	Software Reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0h (R/W) = Normal Mode 1h (R/W) = The module is reset.
0	AUTOIDLE	R/W	0h	Internal interface clock gating strategy 0h (R/W) = Internal Interface OCP clock is free-running 1h (R/W) = Automatic internal OCP clock gating, based on the OCP interface activity

28.4.1.3 GPIO_EOI Register (offset = 20h) [reset = 0h]

Register mask: FFFFFFFFh

GPIO_EOI is shown in Figure 28-10 and described in Table 28-8.

This module supports DMA events with its interrupt signal. This register must be written to after the DMA completes in order for subsequent DMA events to be triggered from this module.

Figure 28-10. GPIO_EOI Register

0	DMAEVT_ACK	W	0h	Write 0 to acknowledge DMA event has been completed. Module will be able to generate another DMA event only when the previous one has been acknowledged using this register. Reads always returns 0. 0h (W) = EOI for interrupt line number 0. Read returns 0. 1h (W) = EOI for interrupt line number 1. Read returns 0.

28.4.1.4 GPIO_IRQSTS_RAW_0 Register (offset = 24h) [reset = 0h]

Register mask: FFFFFFFFh

GPIO_IRQSTS_RAW_0 is shown in Figure 28-11 and described in Table 28-9.

The GPIO_IRQSTS_RAW_0 register provides core status information for the interrupt handling, showing all active events (enabled and not enabled). The fields are read-write. Writing a 1 to a bit sets it to 1, that is, triggers the IRQ (mostly for debug). Writing a 0 has no effect, that is, the register value is not be modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line.

28.4.1.5 GPIO_IRQSTS_RAW_1 Register (offset = 28h) [reset = 0h]

Register mask: FFFFFFFFh

GPIO_IRQSTS_RAW_1 is shown in Figure 28-12 and described in Table 28-10.

The GPIO_IRQSTS_RAW_1 register provides core status information for the interrupt handling, showing all active events (enabled and not enabled). The fields are read-write. Writing a 1 to a bit sets it to 1, that is, triggers the IRQ (mostly for debug). Writing a 0 has no effect, that is, the register value is not be modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line.

28.4.1.6 GPIO_IRQSTS_0 Register (offset = 2Ch) [reset = 0h]

Register mask: FFFFFFFFh

GPIO_IRQSTS_0 is shown in Figure 28-13 and described in Table 28-11.

The GPIO_IRQSTS_0 register provides core status information for the interrupt handling, showing all active events which have been enabled. The fields are read-write. Writing a 1 to a bit clears the bit to 0, that is, clears the IRQ. Writing a 0 has no effect, that is, the register value is not modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line.

28.4.1.7 GPIO_IRQSTS_1 Register (offset = 30h) [reset = 0h]

Register mask: FFFFFFFFh

GPIO_IRQSTS_1 is shown in Figure 28-14 and described in Table 28-12.

The GPIO_IRQSTS_1 register provides core status information for the interrupt handling, showing all active events which have been enabled. The fields are read-write. Writing a 1 to a bit clears the bit to 0, that is, clears the IRQ. Writing a 0 has no effect, that is, the register value is not modified. Only enabled, active events trigger an actual interrupt request on the IRQ output line.

28.4.1.8 GPIO_IRQSTS_SET_0 Register (offset = 34h) [reset = 0h]

Register mask: FFFFFFFFh

GPIO_IRQSTS_SET_0 is shown in Figure 28-15 and described in Table 28-13.

All 1-bit fields in the GPIO_IRQSTS_SET_0 register enable a specific interrupt event to trigger an interrupt request. Writing a 1 to a bit enables the interrupt field. Writing a 0 has no effect, that is, the register value is not modified.

28.4.1.9 GPIO_IRQSTS_SET_1 Register (offset = 38h) [reset = 0h]

Register mask: FFFFFFFFh

GPIO_IRQSTS_SET_1 is shown in Figure 28-16 and described in Table 28-14.

All 1-bit fields in the GPIO_IRQSTS_SET_1 register enable a specific interrupt event to trigger an interrupt request. Writing a 1 to a bit enables the interrupt field. Writing a 0 has no effect, that is, the register value is not modified.

28.4.1.10 GPIO_IRQSTS_CLR_0 Register (offset = 3Ch) [reset = 0h]

Register mask: FFFFFFFFh

GPIO_IRQSTS_CLR_0 is shown in Figure 28-17 and described in Table 28-15.

All 1-bit fields in the GPIO_IRQSTS_CLR_0 register clear a specific interrupt event. Writing a 1 to a bit disables the interrupt field. Writing a 0 has no effect, that is, the register value is not modified.

28.4.1.12 GPIO_IRQWAKEN_0 Register (offset = 44h) [reset = 0h]

Register mask: FFFFFFFFh

GPIO_IRQWAKEN_0 is shown in Figure 28-19 and described in Table 28-17.

Every 1-bit field in the GPIO_IRQWAKEN_0 register enables a specific (synchronous) IRQ request source to generate an asynchronous wakeup (on the appropriate swakeup line). This register allows the user to mask the expected transition on input GPIO from generating a wakeup request. The GPIO_IRQWAKEN_0 is programmed synchronously with the interface clock before any Idle mode request coming from the host processor. Note: In Force-Idle mode, the module wake-up feature is totally inhibited. The wake-up generation can also be gated at module level using the EnaWakeUp bit from GPIO_SYSCONFIG register.

28.4.1.14 GPIO_SYSSTS Register (offset = 114h) [reset = 0h]

Register mask: FFFFFFFFh

GPIO_SYSSTS is shown in Figure 28-21 and described in Table 28-19.

The GPIO_SYSSTS register provides the reset status information about the GPIO module. It is a read-only register; a write to this register has no effect.

28.4.1.15 GPIO_CTRL Register (offset = 130h) [reset = 2h]

Register mask: FFFFFFFFh

GPIO_CTRL is shown in Figure 28-22 and described in Table 28-20.

The GPIO_CTRL register controls the clock gating functionality. The DISABLEMODULE bit controls a clock gating feature at the module level. When set, this bit forces the clock gating for all internal clock paths. Module internal activity is suspended. System interface is not affected by this bit. System interface clock gating is controlled with the AUTOIDLE bit in the system configuration register (GPIO_SYSCONFIG). This bit is to be used for power saving when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

28.4.1.16 GPIO_OE Register (offset = 134h) [reset = FFFFFFFFh]

Register mask: FFFFFFFFh

GPIO_OE is shown in Figure 28-23 and described in Table 28-21.

The GPIO_OE register is used to enable the pins output capabilities. At reset, all the GPIO related pins are configured as input and output capabilities are disabled. This register is not used within the module, its only function is to carry the pads configuration. When the application is using a pin as an output and does not want interrupt generation from this pin, the application can/has to properly configure the Interrupt Enable registers.

28.4.1.17 GPIO_DATAIN Register (offset = 138h) [reset = 0h]

Register mask: FFFFFFFFh

GPIO_DATAIN is shown in Figure 28-24 and described in Table 28-22.

The GPIO_DATAIN register is used to register the data that is read from the GPIO pins. The GPIO_DATAIN register is a read-only register. The input data is sampled synchronously with the interface clock and then captured in the GPIO_DATAIN register synchronously with the interface clock. So, after changing, GPIO pin levels are captured into this register after two interface clock cycles (the required cycles to synchronize and to write the data). When the AUTOIDLE bit in the system configuration register (GPIO_SYSCONFIG) is set, the GPIO_DATAIN read command has a 3 OCP cycle latency due to the data in sample gating mechanism. When the AUTOIDLE bit is not set, the GPIO_DATAIN read command has a 2 OCP cycle latency.

28.4.1.18 GPIO_DATAOUT Register (offset = 13Ch) [reset = 0h]

Register mask: FFFFFFFFh

GPIO_DATAOUT is shown in Figure 28-25 and described in Table 28-23.

The GPIO_DATAOUT register is used for setting the value of the GPIO output pins. Data is written to the GPIO_DATAOUT register synchronously with the interface clock. This register can be accessed with direct read/write operations or using the alternate Set/Clear feature. This feature enables to set or clear specific bits of this register with a single write access to the set data output register (GPIO_SETDATAOUT) or to the clear data output register (GPIO_CLEARDATAOUT) address.

28.4.1.19 GPIO_LEVELDETECT0 Register (offset = 140h) [reset = 0h]

Register mask: FFFFFFFFh

GPIO_LEVELDETECT0 is shown in Figure 28-26 and described in Table 28-24.

The GPIO_LEVELDETECT0 register is used to enable/disable for each input lines the low-level (0) detection to be used for the interrupt request generation. Enabling at the same time high-level detection and low-level detection for one given pin makes a constant interrupt generator.

Figure 28-26. GPIO_LEVELDETECT0 Register

28.4.1.24 GPIO_DEBOUNCINGTIME Register (offset = 154h) [reset = 0h]

Register mask: FFFFFFFFh

GPIO_DEBOUNCINGTIME is shown in Figure 28-31 and described in Table 28-29.

The GPIO_DEBOUNCINGTIME register controls debouncing time (the value is global for all ports). The debouncing cell is running with the debouncing clock (32 kHz), this register represents the number of the clock cycle(s) (31 s long) to be used.

Figure 28-31. GPIO_DEBOUNCINGTIME Register

Graphics Accelerator (SGX)

This chapter describes the graphics accelerator for the device.

NOTE: The Graphics Accelerator (SGX) is not supported for the AMIC120.

Topic **Page**

29.1 Introduction

This chapter describes the 2D/3D graphics accelerator (SGX) for the device.

NOTE: The SGX subsystem is a Texas Instruments instantiation of the POWERVR® SGX530 core from Imagination Technologies Ltd.

This document contains materials that are ©2003-2007 Imagination Technologies Ltd.

POWERVR® and USSE™ are trademarks or registered trademarks of Imagination Technologies Ltd.

The 2D/3D graphics accelerator (SGX) subsystem accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics applications. The SGX subsystem is based on the POWERVR® SGX core from Imagination Technologies. SGX is a new generation of programmable POWERVR graphic cores. The POWERVR SGX530 v1.2.5 architecture is scalable and can target market segments, from portable devices to HMI.

29.1.1 POWERVR SGX Main Features

- 2D and 3D graphics
- Tile-based architecture
- Universal scalable shader engine (USSE™) – multithreaded engine incorporating pixel and vertex shader functionality
- Advanced shader feature set: in excess of OpenGL2.0
- Industry-standard API support: OpenGL ES 1.1 and 2.0, OpenVG v1.0.1
- Fine-grained task switching, load balancing, and power management
- Advanced geometry direct memory access (DMA) driven operation for minimum CPU interaction
- Programmable high-quality image anti-aliasing
- POWERVR SGX core MMU for address translation from the core virtual address to the external physical address (up to 4GB address range)
- Fully virtualized memory addressing for OS operation in a unified memory architecture
- Advanced and standard 2D operations [e.g., vector graphics, BLTs (block level transfers), ROPs (raster operations)]
- 32K stride support

29.1.2 SGX 3D Features

- Deferred pixel shading
- On-chip tile floating point depth buffer
- 8-bit stencil with on-chip tile stencil buffer
- 8 parallel depth/stencil tests per clock
- Scissor test
- Texture support:
  - Cube map
  - Projected textures
  - 2D textures
  - Nonsquare textures
- Texture formats:
  - RGBA 8888, 565, 1555
  - Monochromatic 8, 16, 16f, 32f, 32int
  - Dual channel, 8:8, 16:16, 16f:16f
  - Compressed textures PVR-TC1, PVR-TC2, ETC1
  - Programmable support for YUV 420 and 422 formats for YUV/RGB color conversion
- Resolution support:
  - Frame buffer maximum size = 2048 x 2048
  - Texture maximum size = 2048 x 2048
- Texture filtering:
  - Bilinear, trilinear, anisotropic
  - Independent minimum and maximum control
- Antialiasing:
  - 4x multisampling
  - Up to 16x full scene anti-aliasing
  - Programmable sample positions
- Indexed primitive list support
  - Bus mastered
- Programmable vertex DMA
- Render to texture:
  - Including twiddled formats
  - Auto MipMap generation
- Multiple on-chip render targets (MRT).
  Note: Performance is limited when the on-chip memory is not available.

29.1.3 Universal Scalable Shader Engine (USSE) – Key Features

The USSE is the engine core of the POWERVR SGX architecture and supports a broad range of instructions.

- Single programming model:
  - Multithreaded with 16 simultaneous execution threads and up to 64 simultaneous data instances
  - Zero-cost swapping in, and out, of threads
  - Cached program execution model
  - Dedicated pixel processing instructions
  - Dedicated video encode/decode instructions
- SIMD execution unit supporting operations in:
  - 32-bit IEEE float
  - 2-way 16-bit fixed point
  - 4-way 8-bit integer
  - 32-bit bit-wise (logical only)
- Static and dynamic flow control:
  - Subroutine calls
  - Loops
  - Conditional branches
  - Zero-cost instruction predication
- Procedural geometry:
  - Allows generation of primitives
  - Effective geometry compression
  - High-order surface support
- External data access:
  - Permits reads from main memory using cache
  - Permits writes to main memory
  - Data fence facility
  - Dependent texture reads

29.1.4 Unsupported Features

There are no unsupported SGX530 features for this device.

29.2 Integration

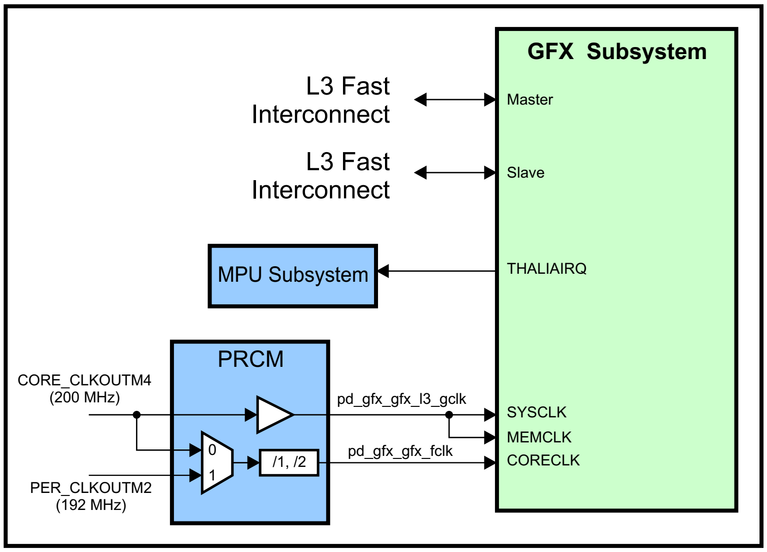

Figure 29-1. SGX530 Integration

29.2.1 SGX530 Connectivity Attributes

The general connectivity attributes of the SGX530 are shown in the following table.

Table 29-1. SGX530 Connectivity Attributes

Attributes	Type
Power domain	GFX Domain
Clock domain	SGX_CLK
Reset signals	SGX_RST
Idle/Wakeup signals	Smart Idle Initiator Standby
Interrupt request	THALIAIRQ (GFXINT) to MPU Subsystem
DMA request	None
Physical address	L3 Fast slave port

29.2.2 SGX530 Clock and Reset Management

The SGX530 uses separate functional and interface clocks. The SYSCLK is the clock for the slave interface and runs at the L3F frequency. The MEMCLK is the clock for the memories and master interface and also runs at the L3F frequency. The CORECLK is the functional clock. It can be sourced from either the L3F clock (CORE_CLKOUTM4) or from the 192 MHz PER_CLKOUTM2 and can optionally be divided by 2.

Table 29-2. SGX530 Clock Signals

Clock signal	Max Freq	Reference / Source	Comments
SYSCLK Interface clock	200 MHz	CORE_CLKOUTM4	pd_gfx_gfx_l3_gclk From PRCM
MEMCLK Memory Clock	200 MHz	CORE_CLKOUTM4	pd_gfx_gfx_l3_gclk From PRCM
CORECLK Functional clock	200 MHz	PER_CLKOUTM2 or CORE_CLKOUTM4	pd_gfx_gfx_fclk From PRCM

29.2.3 SGX530 Pin List

The SGX530 module does not include any external interface pins.

29.3 Functional Description

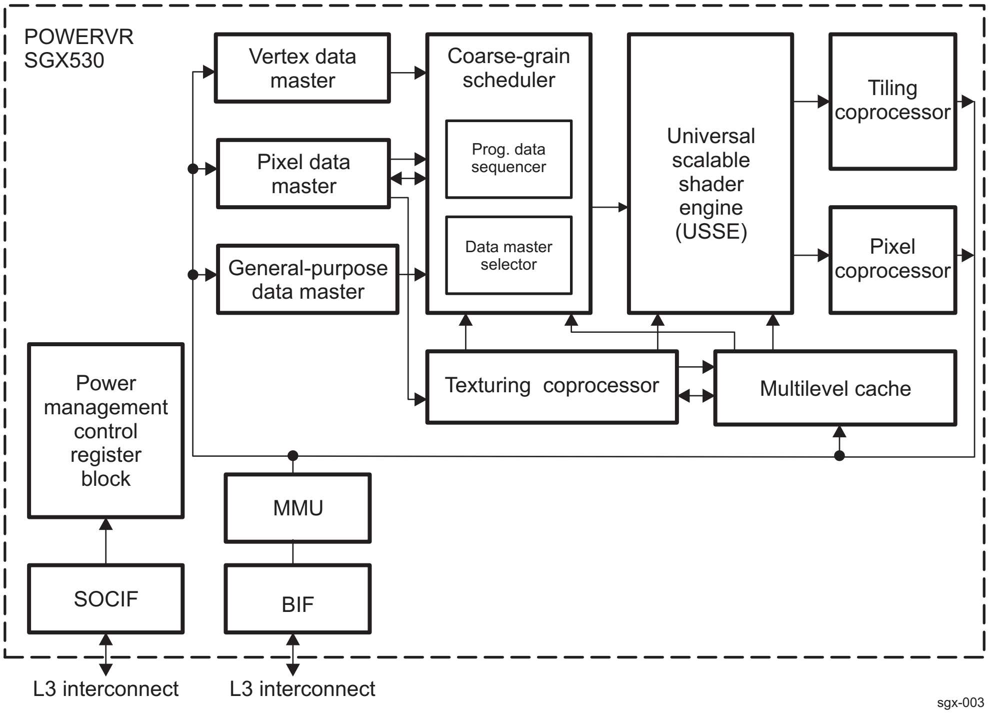
29.3.1 SGX Block Diagram

The SGX subsystem is based on the POWERVR® SGX530 core from Imagination Technologies. The architecture uses programmable and hard coded pipelines to perform various processing tasks required in 2D, 3D, and video processing. The SGX architecture comprises the following elements:

- Coarse grain scheduler
  - Programmable data sequencer (PDS)
  - Data master selector (DMS)
- Vertex data master (VDM)
- Pixel data master (PDM)
- General-purpose data master
- USSE
- Tiling coprocessor
- Pixel coprocessor
- Texturing coprocessor
- Multilevel cache

Figure 29-2 shows a block diagram of the SGX cores.

Figure 29-2. SGX Block Diagram



29.3.2 SGX Elements Description

The coarse grain scheduler (CGS) is the main system controller for the POWERVR SGX architecture. It consists of two stages, the DMS and the PDS. The DMS processes requests from the data masters and determines which tasks can be executed given the resource requirements. The PDS then controls the loading and processing of data on the USSE.

There are three data masters in the SGX core:

- The VDM is the initiator of transform and lighting processing within the system. The VDM reads an input control stream, which contains triangle index data and state data. The state data indicates the PDS program, size of the vertices, and the amount of USSE output buffer resource available to the VDM. The triangle data is parsed to determine unique indices that must be processed by the USSE. These are grouped together according to the configuration provided by the driver and presented to the DMS.

- The PDM is the initiator of rasterization processing within the system. Each pixel pipeline processes pixels for a different half of a given tile, which allows for optimum efficiency within each pipe due to locality of data. It determines the amount of resource required within the USSE for each task. It merges this with the state address and issues a request to the DMS for execution on the USSE.
- The general-purpose data master responds to events within the system (such as end of a pass of triangles from the ISP, end of a tile from the ISP, end of render, or parameter stream breakpoint event). Each event causes either an interrupt to the host or synchronized execution of a program on the PDS. The program may, or may not cause a subsequent task to be executed on the USSE.

The USSE is a user-programmable processing unit. Although general in nature, its instructions and features are optimized for three types of task: processing vertices (vertex shading), processing pixels (pixel shading), and video/imaging processing.

The multilevel cache is a 2-level cache consisting of two modules: the main cache and the mux/arbiter/demux/decompression unit (MADD). The MADD is a wrapper around the main cache module designed to manage and format requests to and from the cache, as well as providing Level 0 caching for texture and USSE requests. The MADD can accept requests from the PDS, USSE, and texture address generator modules. Arbitration, as well as any required texture decompression, are performed between the three data streams.

The texturing coprocessor performs texture address generation and formatting of texture data. It receives requests from either the iterators or USSE modules and translates these into requests in the multilevel cache. Data returned from the cache are then formatted according to the texture format selected, and sent to the USSE for pixel-shading operations.

To process pixels in a tiled manner, the screen is divided into tiles and arranged as groups of tiles by the tiling coprocessor. An inherent advantage of tiling architecture is that a large amount of vertex data can be rejected at this stage, thus reducing the memory storage requirements and the amount of pixel processing to be performed.

The pixel coprocessor is the final stage of the pixel-processing pipeline and controls the format of the final pixel data sent to the memory. It supplies the USSE with an address into the output buffer and then USSE returns the relevant pixel data. The address order is determined by the frame buffer mode. The pixel coprocessor contains a dithering and packing function.

Programmable Real-Time Unit Subsystem and Industrial Communication Subsystem (PRU-ICSS)

This chapter describes the PRU-ICSS for the device.

Topic **Page**

30.1 Introduction

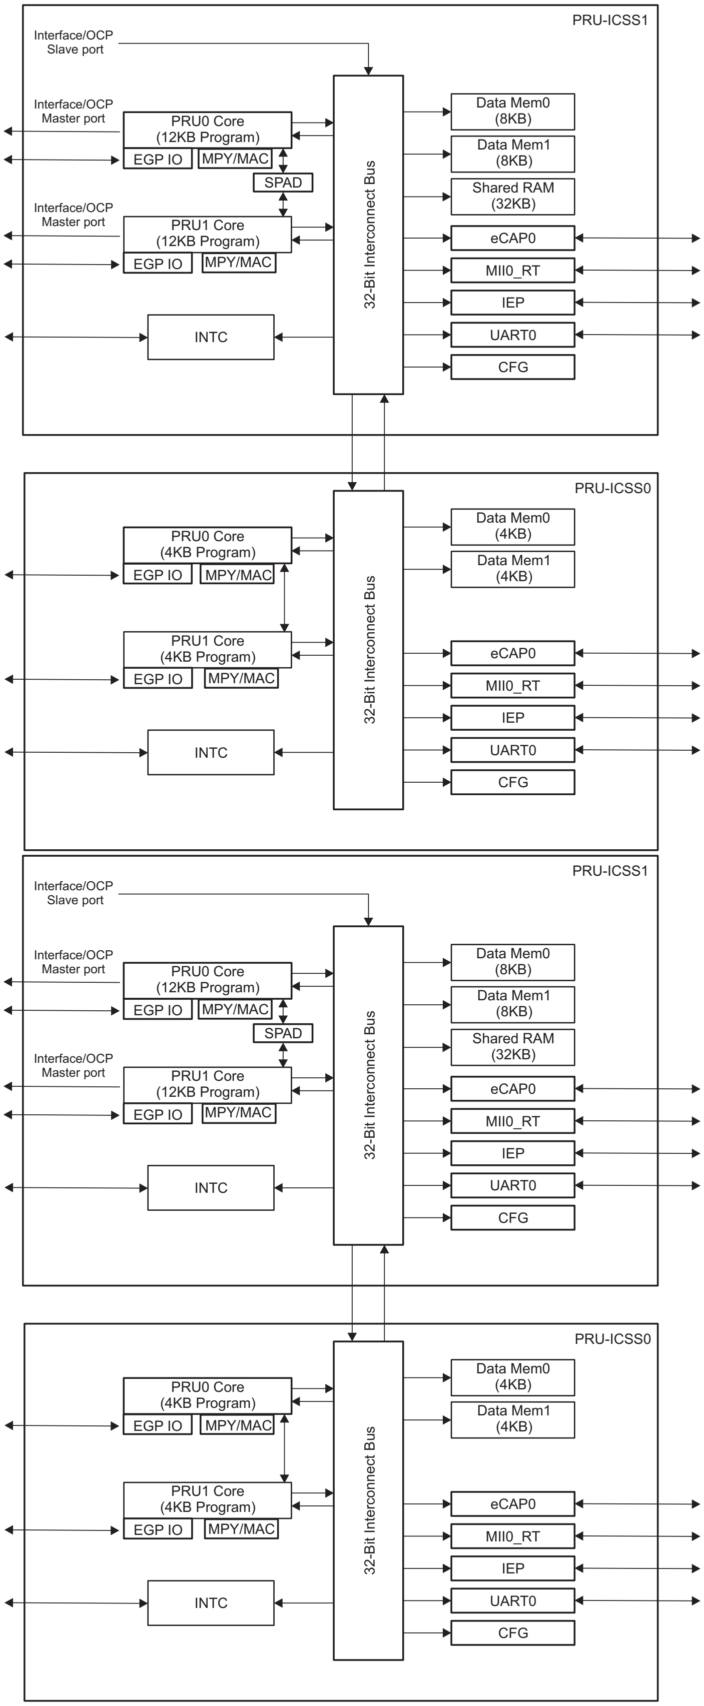
The Programmable Real-Time Unit Subsystem and Industrial Communication Subsystem (PRU-ICSS) consists of dual 32-bit RISC cores (Programmable Real-Time Units, or PRUs), shared, data, and instruction memories, internal peripheral modules, and an interrupt controller (INTC). The programmable nature of the PRU-ICSS, along with their access to pins, events and all SoC resources, provides flexibility in implementing fast real-time responses, specialized data handling operations, custom peripheral interfaces, and in offloading tasks from the other processor cores of the system-on-chip (SoC).

This device contains two subsystems: PRU-ICSS1 and PRU-ICSS0. PRU-ICSS1 is considered a superset of PRU-ICSS0. Figure 30-1 details PRU-ICSS1 and PRU-ICSS0.

The PRU cores within the subsystems have access to all resources on the SoC through the Interface/OCP Master port, and the external host processors can access the PRU-ICSS resources through the Interface/OCP Slave port. The 32-bit interconnect bus connects the various internal and external masters to the resources inside the PRU-ICSS. The INTC handles system input events and posts events back to the device-level host CPU.

The PRU cores are programmed with a small, deterministic instruction set. Each PRU can operate independently or in coordination with each other and can also work in coordination with the device-level host CPU. This interaction between processors is determined by the nature of the firmware loaded into the PRU's instruction memories.

Figure 30-1. PRU-ICSS Block Diagram



30.1.1 Features

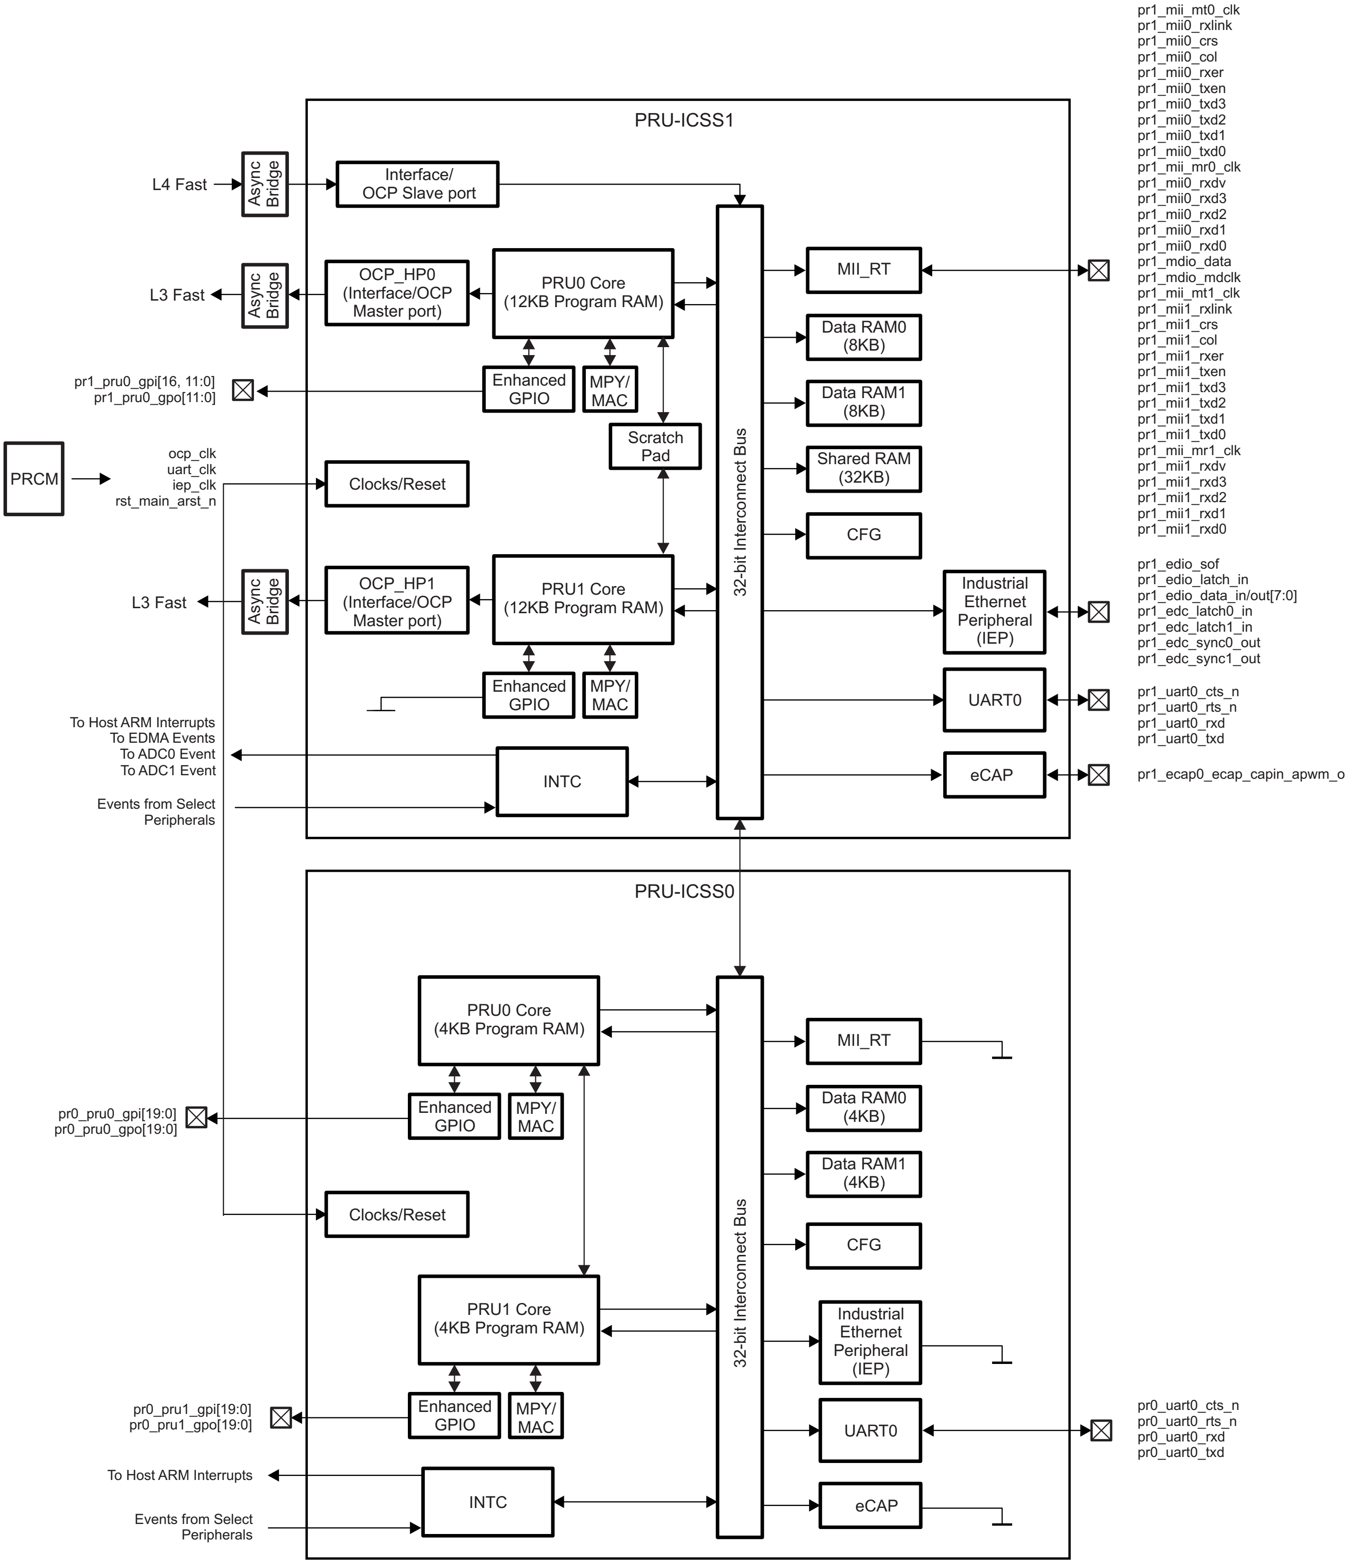
The PRU-ICSS includes the following main features:

- Two PRUs each with:
  - Program memory (PRU-ICSS1 - 12KB, PRU-ICSS0 - 4KB)
  - Data memory (PRU-ICSS1 - 8KB, PRU-ICSS0 - 4KB)
  - High Performance Interface/OCP Master port for accessing external memories[1]
  - Enhanced GPIO (EGPIO) with async capture, serial, 9ch Sigma Delta[2], and 3ch EnDat 2.2 support
  - Multiplier with optional accumulation (MPY/MAC)
- One scratch pad (SPAD) memory (only PRU-ICSS1)
  - 3 Banks of 30 32-bit registers
- Broadside direct connect between PRU cores within subsystem
- 32KB general purpose shared memory (only PRU-ICSS1)
- One Interrupt Controller (INTC)
  - Up to 64 input events supported
  - Interrupt mapping to 10 interrupt channels
  - 10 Host interrupts (2 to PRU0 and PRU1, 1 to PRU-ICSS1 and PRU-ICSS0, 7 output to chip level)
  - Each system event can be enabled and disabled
  - Each host event can be enabled and disabled
  - Hardware prioritization of events
- 16 software events generated by 2 PRUs
- One Ethernet MII_RT module with two MII ports and configurable connections to PRUs[3][4]
- One Industrial Ethernet Peripheral (IEP) to manage/generate Industrial Ethernet functions[3]
  - One Industrial Ethernet timer with 10 capture[4] and 16 compare events
  - Two Industrial Ethernet sync signals and two latch signals[4]
  - Two Industrial Ethernet 16-bit watchdog timers[4]
  - Industrial Ethernet digital IOs
- One 16550-compatible UART with a dedicated 192-MHz clock, supporting up to 12Mbaud for PROFIBUS DP[3]
- One Enhanced Capture Module (ECAP)[3]
- Flexible power management support
- Integrated 32-bit interconnect bus for connecting the various internal and external masters to the resources inside the PRU-ICSS
- Interface/OCP Slave port for external masters to access PRU-ICSS memories[1]
- Optional address translation for PRU transaction to External Host[1]
- All memories within the PRU-ICSS support parity

30.2 Integration

The device includes two Programmable Real-Time Unit Subsystem and Industrial Communication Subsystem (PRU-ICSS), each consisting of two independent Programmable Real-time Units (PRUs). Each PRU is a 32-bit Load/Store RISC processor with dedicated memories. The PRU-ICSS integration is shown in Figure 30-2.

Figure 30-2. PRU-ICSS Integration



For the availability of all features, see the device features in Chapter 1, *Introduction* SPRUHL7.

30.2.1 PRU-ICSS Connectivity Attributes

The general connectivity attributes for the PRU subsystem are shown in Table 30-1.

Table 30-1. PRU-ICSS Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_PRU_ICSS_OCP_GCLK (OCP clock) PD_PER_PRU_ICSS_IEP_GCLK (IEP clock) PD_PER_PRU_ICSS_UART_GCLK (UART clock)
Reset Signals	PRU_ICSS_LRST_N
Idle/Wakeup Signals	Standby Idle
Interrupt Requests	14 Interrupts pr1_host_intr[7:6](1) to MPU Subsystem pr1_host_intr[4:1](1) to MPU Subsystem pr1_host_intr[0](1) to MPU Subsystem, ADC0, and ADC1 pr0_host_intr[7:6](1) to MPU Subsystem pr0_host_intr[4:0](1) to MPU Subsystem
DMA Requests	No dedicated DMA events but pr1_host_intr[7:6](1) interrupt outputs also connected as DMA events
Physical Address	L3 Fast Slave Port

(1) pr<*k*>_host_intr[0:7] corresponds to Host-2 to Host-9 of the PRU-ICSS<*k*> interrupt controller.

30.2.2 PRU-ICSS Clock and Reset Management

The PRU-ICSS module uses the following functional and OCP interface clocks.

Table 30-2. PRU-ICSS Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
ocp_clk Interface Clock	225 MHz	CORE_CLKOUTM4 or Display PLL CLKOUT	pd_per_pru_icss_ocp_gclk from PRCM Clocks both L3 master and L3F slave
uart_clk Functional Clock	192 MHz	PER_CLKOUTM2	pd_per_pru_icss_uart_gclk from PRCM UART Clock
iep_clk Functional Clock	200 MHz	CORE_CLKOUTM4	pd_per_pru_icss_iep_gclk from PRCM Industrial Ethernet Peripheral Clock

NOTE: Default frequency of ocp_clk is 200 MHz using CORE_CLKOUTM4 reference clock. The max frequency 225 MHz is achievable through Display PLL CLKOUT. Refer to Section 13.2 for DSS limitations when configuring this PLL for frequencies >200 MHz.

30.2.3 PRU-ICSS Pin List

The PRU-ICSS external interface signals are shown in Table 30-3. The PRU GPI/GPO pin function depends on the operation mode. Refer to Table 30-3 for a complete list of pin functions for each mode.

Table 30-3. PRU-ICSS Pin List

Pin	Type	Description
PRU-ICSS1		
pr1_mii_mr0_clk	I	MII0 Receive Clock
pr1_mii0_rxdv	I	MII0 Receive Data Valid
pr1_mii0_rxd[3:0]	I	MII0 Receive Data

pr1_pru0_gpo[11:0]	IO	PRU-ICSS1 PRU0 Register R30 (GPO) Outputs
pr1_pru0_gpi[11:0]	IO	PRU-ICSS1 PRU0 Register R31 (GPI) Inputs
pr1_pru0_gpi[16]	IO	PRU-ICSS1 PRU0 Register R31 (GPI) Input

Table 30-3. PRU-ICSS Pin List (continued)

Pin	Type	Description
	PRU-ICSS0	
pr0_uart0_cts_n	I	UART Clear to Send
pr0_uart0_rts_n	O	UART Request to Send
pr0_uart0_rxd	I	UART Receive Data
pr0_uart0_txd	O	UART Transmit Data
pr0_pru0_gpo[19:0]	IO	PRU-ICSS0 PRU0 Register R30 (GPO) Outputs
pr0_pru0_gpi[19:0]	IO	PRU-ICSS0 PRU0 Register R31 (GPI) Inputs
pr0_pru1_gpo[19:0]	IO	PRU-ICSS0 PRU1 Register R30 (GPO) Outputs
pr0_pru1_gpi[19:0]	IO	PRU-ICSS0 PRU1 Register R31 (GPI) Inputs

Note: R30 may not be initialized after reset. To avoid outside effect, R30 should be initialized before PINMUX configuration.

30.3 PRU-ICSS Memory Map Overview

The PRU-ICSS comprises various distinct addressable regions that are mapped to both a local and global memory map. The local memory maps are maps with respect to the PRU point of view. Each PRU-ICSS can also access the memories within the other subsystem without going through an external port, as described in Section 30.3.1.2.The global memory maps are maps with respect to the Host point of view, but can also be accessed by the PRU-ICSS. All global or external accesses are routed through PRU-ICSS1. PRU-ICSS0 does not have direct access to memories outside the subsystem.

30.3.1 Local Memory Map

The PRU-ICSS memory map is documented in Table 30-4 (Instruction Space) and in Table 30-5 (Data Space). Note that these two memory maps are implemented inside the PRU-ICSS and are local to the components of the PRU-ICSS.

30.3.1.1 Local Instruction Memory Map

Each PRU has a dedicated Instruction Memory (8KB12KB for PRU-ICSS1, 4KB for PRU-ICSS0) which needs to be initialized by a Host processor before the PRU executes instructions. This region is only accessible to masters via the interface/ OCP slave port when the PRU is not running.

Table 30-4. Local Instruction Memory Map

Start Address	PRU-ICSS1		PRU-ICSS0	
	PRU0	PRU1	PRU0	PRU1
0x0000_0000	12KB IRAM	12KB IRAM	4KB IRAM	4KB IRAM

30.3.1.2 Local Data Memory Map

The local data memory map in Table 30-5 allows each PRU core to access the PRU-ICSS addressable regions (both its own subsystem and the other subsystem) and the external host’s memory map.

The PRU accesses the other PRU-ICSS memory map through an expansion port starting at address 0x0004_0000. The address seen by the other PRU-ICSS will be translated by hardware, subtracting 0x0004_0000.

The PRU accesses the external Host memory map through the Interface/OCP Master port (System OCP_HP0/1) starting at address 0x0008_0000. By default, memory addresses between 0x0000_0000 – 0x0007_FFFF will correspond to the PRU-ICSS local address in Table 30-5. To access an address between 0x0000_0000–0x0007_FFFF of the external Host map, the address offset of –0x0008_0000 feature is enabled through the PMAO register of the PRU-ICSS CFG register space. Note that all external accesses to or from PRU-ICSS0 are routed through PRU-ICSS1.

Table 30-5. Local Data Memory Map

Start Address	PRU-ICSS1		PRU-ICSS0	
	PRU0	PRU1	PRU0	PRU1
0x0000_0000	PRU-ICSS1 Data 8KB RAM 0(1)	PRU-ICSS1 Data 8KB RAM 1(1)	PRU-ICSS0 Data 4KB RAM 0(1)	PRU-ICSS0 Data 4KB RAM 1(1)
0x0000_2000	PRU-ICSS1 Data 8KB RAM 1(1)	PRU-ICSS1 Data 8KB RAM 0(1)	PRU-ICSS0 Data 4KB RAM 1(1)	PRU-ICSS0 Data 4KB RAM 0(1)
0x0001_0000	PRU-ICSS1 Shared Data 32KB RAM 2	PRU-ICSS1 Shared Data 32KB RAM 2	Reserved	Reserved
0x0002_0000	PRU-ICSS1 INTC	PRU-ICSS1 INTC	PRU-ICSS0 INTC	PRU-ICSS0 INTC

0x0002_2400	Reserved	Reserved	Reserved	Reserved

(1) Data RAM0 is intended to be the primary data memory for PRU0, as is Data RAM1 for PRU1. However, both PRU cores can access Data RAM0 and Data RAM1 to pass information between PRUs. Each PRU core accesses their intended Data RAM at address 0x0000_0000 and the other Data RAM at address 0x0000_2000.

Table 30-5. Local Data Memory Map (continued)

Start Address	PRU-ICSS1		PRU-ICSS0

(2) All external accesses to or from PRU-ICSS0 are routed through PRU-ICSS1.

30.3.2 Global Memory Map

The global view of the PRU-ICSS internal memories and control ports is shown in Table 30-6. The offset addresses of each region are implemented inside the PRU-ICSS but the global device memory mapping places the PRU-ICSS slave port in the address range shown in the external Host top-level memory map.

The global memory map is with respect to the Host point of view, but it can also be accessed by the PRU-ICSS. Note that PRU0 and PRU1 can use either the local or global addresses to access their internal memories, but using the local addresses will provide access time several cycles faster than using the global addresses. This is because when accessing via the global address the access needs to be routed through the switch fabric outside PRU-ICSS and back in through the PRU-ICSS slave port.

Each of the PRUs can access the rest of the device memory (including memory mapped peripheral and configuration registers) using the global memory space addresses. See Table 30-6, *Memory Map*, for base addresses of each module in the device. Note that all global or external accesses to or from PRU-ICSS0 are routed through PRU-ICSS1.

Table 30-6. Global Memory Map

30.4 Functional Description

30.4.1 PRU Cores

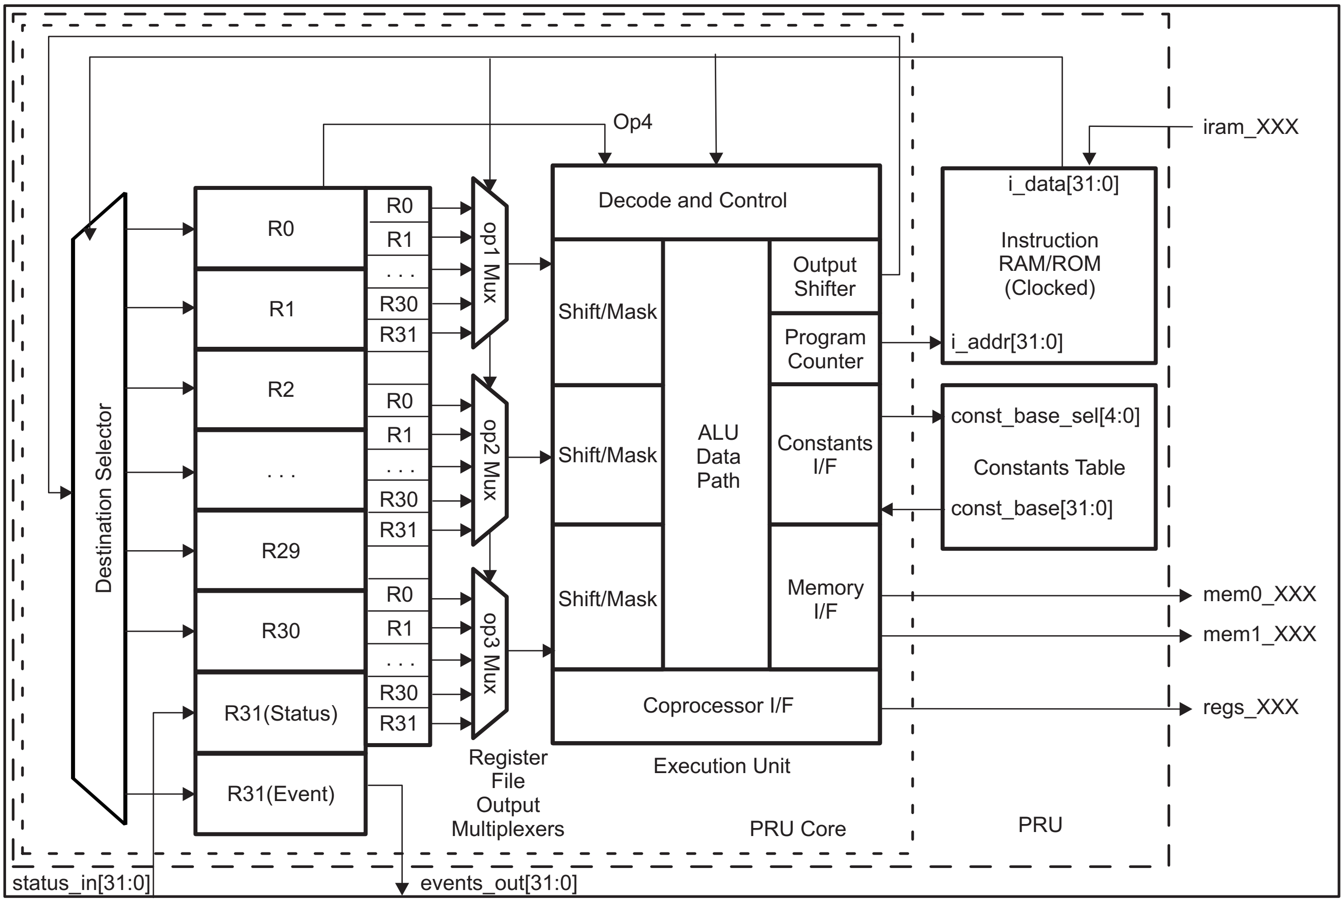
The PRU is a processor optimized for performing embedded tasks that require manipulation of packed memory mapped data structures, handling of system events that have tight real-time constraints and interfacing with systems external to the SoC. The PRU is both very small and very efficient at handling such tasks.

The major attributes of the PRU are as follows.

Attribute	Value
IO Architecture	Load / Store
Data Flow Architecture	Register to Register
Core Level Bus Architecture	
Type	4-Bus Harvard (1 Instruction, 3 Data)
Instruction I/F	32-Bit
Memory I/F 0	32-Bit
Memory I/F 1	32-Bit
Execution Model	
Issue Type	Scalar
Pipelining	None (Purposefully)
Ordering	In Order
ALU Type	Unsigned Integer
Registers	
General Purpose (GP)	30(R1 – R30)
External Status	1 (R31)
GP / Indexing	1 (R0)
Addressability in Instruction	Bit, Byte (8-bit), Halfword (16-bit), Word (32-bit), Pointer
Addressing Modes	
Load Immediate	16-bit Immediate
Load / Store – Memory	Register Base + Register Offset Register Base + 8-bit Immediate Offset Register Base with auto increment / decrement Constant Table Base + Register Offset Constant Table Base + 8-bit Immediate Offset Constant Table Base with auto increment / decrement
Data Path Width	32-Bits
Instruction Width	32-Bits
Accessibility to Internal PRU Structures	Provides 32-bit slave with three regions: • Instruction RAM • Control / Status registers • Debug access to internal registers (R0-R31) and constant table

The processor is based on a four-bus architecture which allows instructions to be fetched and executed concurrently with data transfers. In addition, an input is provided in order to allow external status information to be reflected in the internal processor status register. Figure 30-3 shows a block diagram of the processing element and the associated instruction RAM/ROM that contains the code that is to be executed.

Figure 30-3. PRU Block Diagram



30.4.1.1 Constant Table

The PRU Constants Table is a structure of hard-coded memory addresses for commonly used peripherals and memories.

The constants table exists to more efficiently load/store data to these commonly accessed addresses by:

- Reduce a PRU instruction by not needing to pre-load an address into the internal register file before loading/storing data to memory address.
- Maximizing the usage of the PRU register file for embedded processing applications by moving many of the commonly used constant or deterministically calculated base addresses from the internal register file to an external table.

Table 30-7. PRU0/1 Constant Table

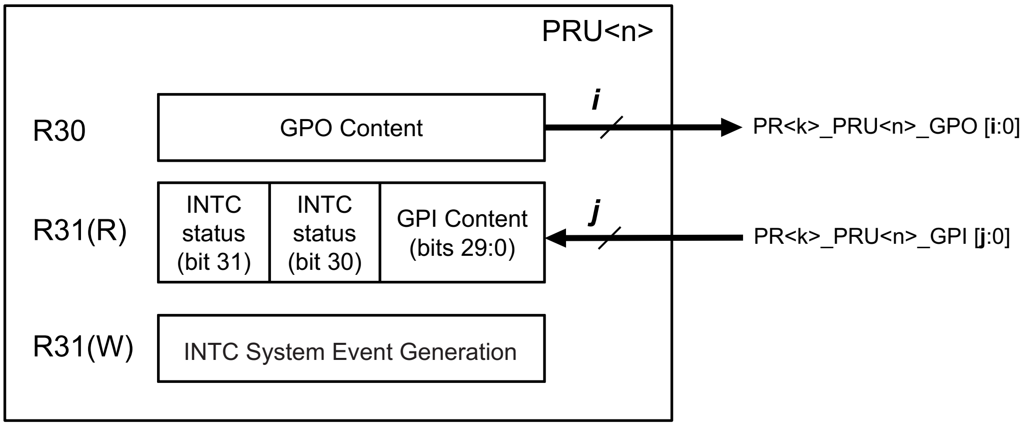
Entry No.	Region Pointed To	Value [31:0]
0	PRU-ICSS INTC (local)	0x0002_0000
1	DMTIMER2	0x4804_0000
2	I2C1	0x4802_A000
3	PRU-ICSS eCAP (local)	0x0003_0000
4	PRU-ICSS CFG (local)	0x0002_6000
5	MMCSD0	0x4806_0000
6	MCSPI0	0x4803_0000
7	PRU-ICSS UART0 (local)	0x0002_8000
8	McASP0 DMA	0x4600_0000
9	CPSW	0x4A10_0000
10	Reserved	0x4831_8000
11	UART1	0x4802_2000
12	UART2	0x4802_4000
13	Reserved	0x4831_0000
14	DCAN0	0x481C_C000
15	DCAN1	0x481D_0000
16	MCSPI1	0x481A_0000
17	I2C2	0x4819_C000
18	eHRPWM1/eCAP1/eQEP1	0x4830_0000
19	eHRPWM2/eCAP2/eQEP2	0x4830_2000
20	eHRPWM3/eCAP3/eQEP3	0x4830_4000
21	PRU-ICSS MDIO (local)	0x0003_2400
22	Mailbox0	0x480C_8000
23	Spinlock	0x480C_A000
24	PRU-ICSS PRU0/1 Data RAM (local)	0x0000_0n00, n = c24_blk_index[3:0]
25	PRU-ICSS PRU1/0 Data RAM (local)	0x0000_2n00, n = c25_blk_index[3:0]
26	PRU-ICSS IEP (local)	0x0002_En00, n = c26_blk_index[3:0]
27	PRU-ICSS MII_RT (local)	0x0003_2n00, n = c27_blk_index[3:0]
28	PRU-ICSS Shared RAM (local)	0x00nn_nn00, nnnn = c28_pointer[15:0]
29	TPCC (EDMA)	0x49nn_nn00, nnnn = c29_pointer[15:0]
30	L3 OCMC0 SRAM	0x40nn_nn00, nnnn = c30_pointer[15:0]
31	EMIF0 DDR Base	0x80nn_nn00, nnnn = c31_pointer[15:0]

NOTE: The addresses in constants entries 24–31 are partially programmable. Their programmable bit field (e.g., c24_blk_index[3:0]) is programmable through the PRU CTRL register space. As a general rule, the PRU should configure this field before using the partially programmable constant entries.

30.4.1.2 PRU Module Interface to PRU I/Os and INTC

The PRU module interface consists of the PRU internal registers 30 and 31 (R30 and R31). Figure 30-4 shows the PRU module interface and the functionality of R30 and R31. The register R31 serves as an interface with the dedicated PRU general purpose input (GPI) pins and INTC. Reading R31 returns status information from the GPI pins and INTC via the PRU Real Time Status Interface. Writing to R31 generates PRU system events via the PRU Event Interface. The register R30 serves as an interface with the dedicated PRU general purpose output (GPO) pins. Note that the R30/R31 GPO or GPI register content changes depending on the selected configuration (i.e. MII_RT, Sigma Delta, Parallel Capture, etc). See the subsequent sections for more details.

Figure 30-4. PRU Module Interface



30.4.1.2.1 Real-Time Status Interface Mapping (R31): Interrupt Events Input

The PRU Real-Time Status Interface directly feeds information into register 31 (R31) of the PRU's internal register file. The firmware on the PRU uses the status information to make decisions during execution. The status interface is comprised of signals from different modules inside of the PRU-ICSS which require some level of interaction with the PRU. More details on the Host interrupts imported into bit 30 and 31 of register R31 of both the PRUs is provided in Section 30.4.2, *Interrupt Controller*.

Table 30-8. Real-Time Status Interface Mapping (R31) Field Descriptions

Bit	Field	Value	Description
31	pru_intr_in[1]		PRU Host Interrupt 1 from local INTC
30	pru_intr_in[0]		PRU Host Interrupt 0 from local INTC
29-0	pru<n>_r31_status[29:0]		Status inputs from primary input via Enhanced GPI port

30.4.1.2.2 Event Interface Mapping (R31): PRU System Events

This PRU Event Interface directly feeds pulsed event information out of the PRU's internal ALU. These events are exported out of the PRU-ICSS and need to be connected to the system interrupt controller at the SoC level. The event interface can be used by the firmware to create interrupts from the PRU to the Host processor.

Figure 30-5. Event Interface Mapping (R31)

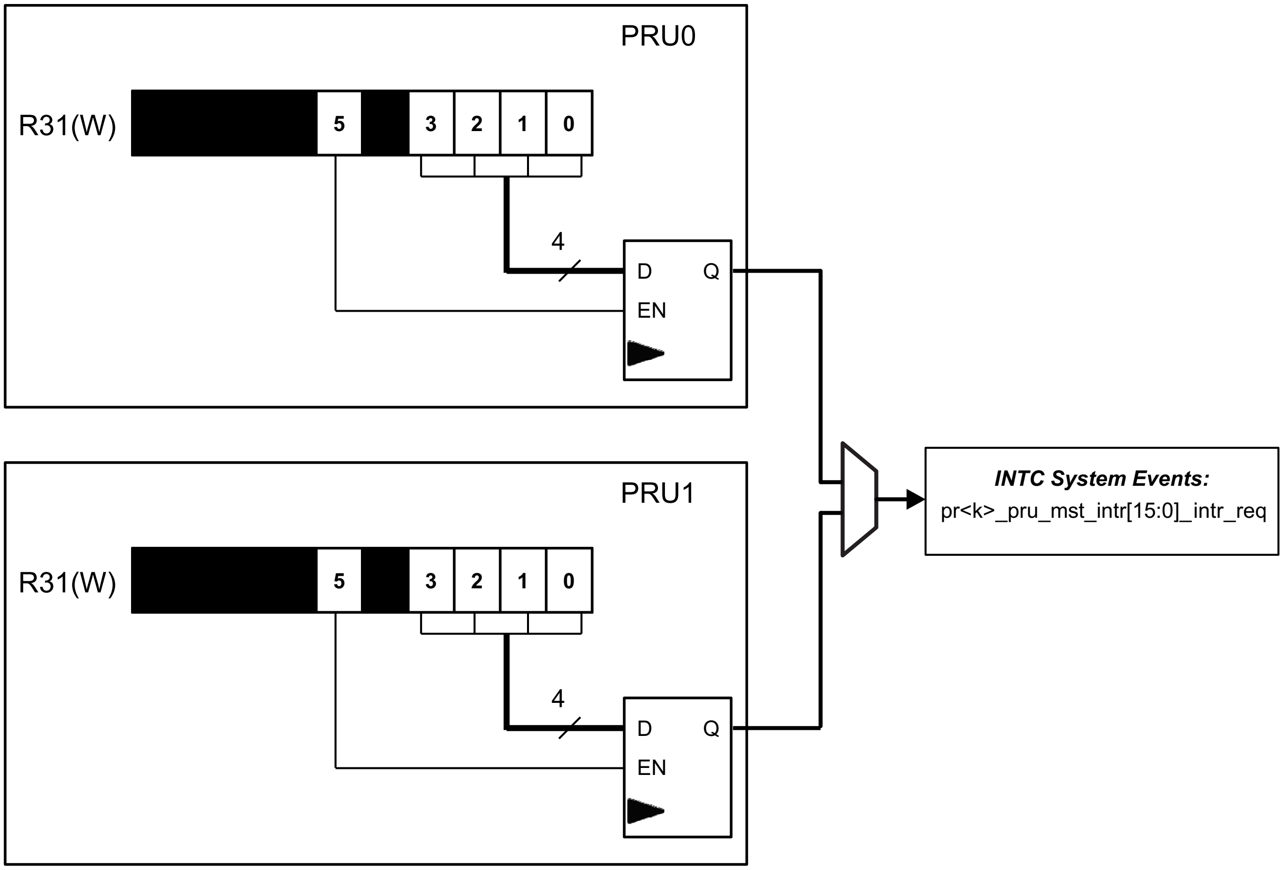


Table 30-9. Event Interface Mapping (R31) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved		
5	pru<n>_r31_vec_valid		Valid strobe for vector output
4	Reserved		
3-0	pru<n>_r31_vec[3:0]		Vector output

Simultaneously writing a '1' to pru<n>_r31_vec_valid (R31 bit 5) and a channel number from 0-15 to pru<n>_r31_vec[3:0] (R31 bits 3:0) creates a pulse on the output of the corresponding pr<k>_pru_mst_intr[x]_intr_req INTC system event. For example, writing '100000' will generate a pulse on pr<k>_pru_mst_intr[0]_intr_req, writing '100001' will generate a pulse on pr<k>_pru_mst_intr[1]_intr_req, and so on to where writing '101111' will generate a pulse on pr<k>_pru_mst_intr[15]_intr_req and writing '0xxxxx' will not generate any system event pulses. The output values from both PRU cores in a subsystem are ORed together.

The output channels 0-15 are connected to the PRU-ICSS INTC system events 16-31, respectively. This allows the PRU to assert one of the system events 16-31 by writing to its own R31 register. The system event is used to either post a completion event to one of the host CPUs (ARM) or to signal the other PRU. The host to be signaled is determined by the system event to interrupt channel mapping (programmable). The 16 events are named as pr<k>_pru_mst_intr<15:0>_intr_req. For more details, see Section 30.4.2, *Interrupt Controller*.

30.4.1.2.3 General-Purpose Inputs (R31): Enhanced PRU GP Module

The PRU-ICSS implements an enhanced General-Purpose Input/Output (GPIO) module that supports the following general-purpose input modes: direct input, 16-bit parallel capture, and 28-bit serial shift in. Register R31 serves as an interface with the general-purpose inputs.

Table 30-10 describes the input modes in detail.

NOTE: Each PRU core can only be configured for one GPI mode at a time. Each mode uses the same R31 signals and internal register bits for different purposes. A summary is found in Table 30-11

NOTE: The GPCFGn register, bit PR1_PRU0_GP_MUX_SEL in the PRU-ICSS CFG register space needs to be set to 0x0 for GP mode. For a given PRU core, the following IO modes are mutually exclusive: GP mode, Sigma Delta mode, and Peripheral I/F mode.

Table 30-10. PRU R31 (GPI) Modes

Mode	Function	Configuration
Direct input	GPI[29:0] feeds directly into the PRU R31	Default mode
16-bit parallel capture	DATAIN[0:15] is captured by the posedge or negedge of CLOCKIN	• Enabled by CFG_GPCFGn register • CLOCKIN edge selected by CFG_GPCFGn register
28-bit shift in	DATAIN is sampled and shifted into a 28-bit shift register. Shift Counter (Cnt_16) feature uses ... • Shift Counter (Cnt_16) feature is mapped to pru<n>_r31_status[28]. • SB (Start Bit detection) feature is mapped to pru<n>_r31_status[29]	• Enabled by CFG_GPCFGn register • Cnt_16 is self clearing and is connected to the PRU INTC • Start Bit (SB) is cleared by CFG_GPCFGn register
MII_RT	mii_rt_r31_status [29:0] internally driven by the MII_RT module	Enabled by CFG

Table 30-11. PRU GPI Signals and Configurations(1)

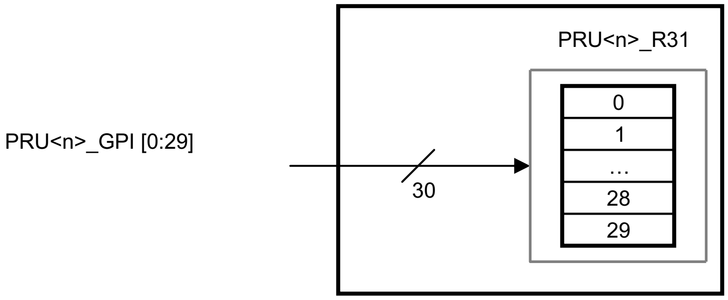
pr<k>_pru<n>_gpi27	GPI27		
pr<k>_pru<n>_gpi28	GPI28		
pr<k>_pru<n>_gpi29	GPI29		

NOTE: Some devices may not pin out all 30 bits of R31. For which pins are available on this device, see Section 30.2.3, *PRU-ICSS Pin List*. See the device data sheet for device-specific pin mapping.

30.4.1.2.3.1 Direct Input

The pru<n>_r31_status [0:29] bits of the internal PRU register file are mapped to device-level, general purpose input pins (PRU<n>_GPI [0:29]). In GPI Direct Input mode, PRU<n>_GPI [0:29] feeds directly to pru<n>_r31_status [0:29]. There are 30 possible general purpose inputs per PRU core; however, some devices may not pin out all of these signals. See the device-specific data sheet for device-specific pin mapping.

Figure 30-6. PRU R31 (GPI) Direct Input Mode Block Diagram

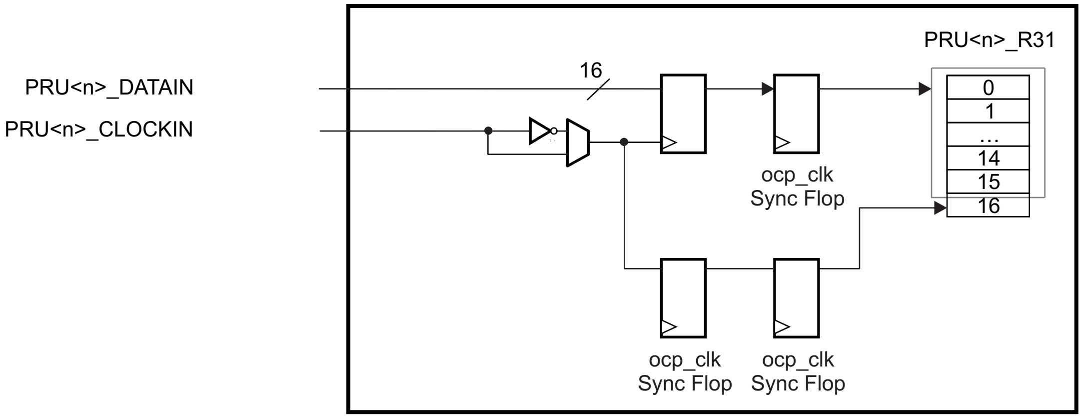


30.4.1.2.3.2 16-Bit Parallel Capture

The pru<n>_r31_status [0:15] and pru<n>_r31_status [16] bits of the internal PRU register file mapped to device-level, general purpose input pins (PRU<n>_DATAIN [0:15] and PRU<n>_CLOCKIN, respectively). PRU<n>_CLOCKIN is designated for an external strobe clock, and is used to capture PRU<n>_DATAIN [0:15].

The PRU<n>_DATAIN can be captured either by the positive or the negative edge of PRU<n>_CLOCK, programmable through the PRU-ICSS CFG register space. If the clocking is configured through the PRU-ICSS CFG register to be positive, then it will equal PRU<n>_CLOCK; however, if the clocking is configured to be negative, then it will equal PRU<n>_CLOCK inverted.

Figure 30-7. PRU R31 (GPI) 16-Bit Parallel Capture Mode Block Diagram



30.4.1.2.3.3 28-Bit Shift In

In 28-bit shift in mode, the device-level, general-purpose input pin PRU<n>_DATAIN is sampled and shifted into a 28-bit shift register on an internal clock pulse. The register fills in lsb order (from bit 0 to 27) and then overflows into a bit bucket. The 28-bit register is mapped to pru<n>_r31_status [0:27] and can be cleared in software through the PRU-ICSS CFG register space.

Note, the PRU will continually capture and shift the DATAIN input when the GPI mode has been set to 28-bit shift in.

The shift rate is controlled by the effective divisor of two cascaded dividers applied to the ocp_clk. These cascaded dividers can each be configured through the PRU-ICSS CFG register space to a value of {1, 1.5, ..., 16}. Table 30-12 shows sample, effective clock values and the divisor values that can be used to generate these clocks.

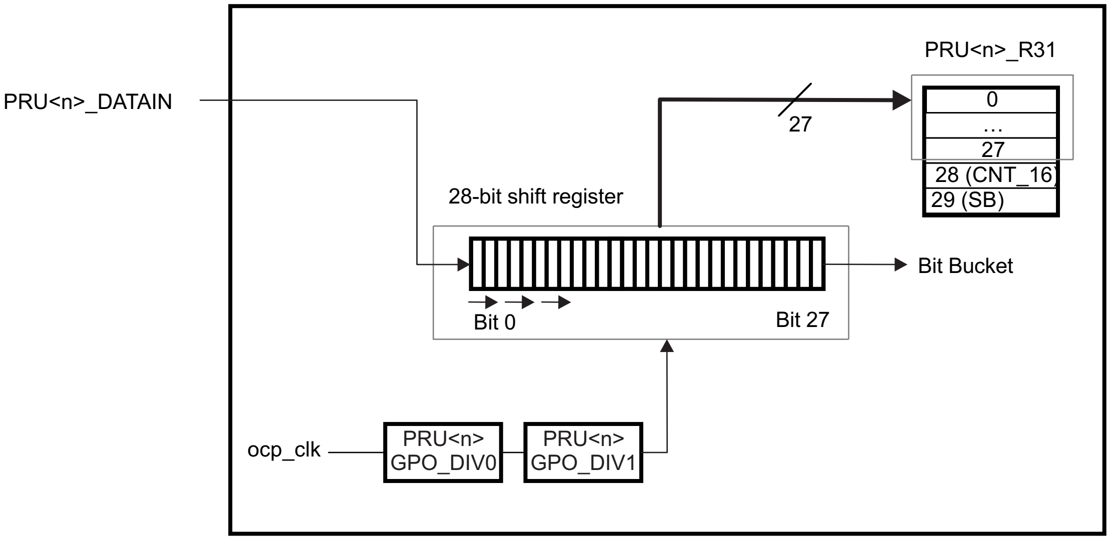
Table 30-12. Effective Clock Values

Generated clock	PRU<n>_GPI_DIV0	PRU<n>_GPI_DIV1
8-MHz	12.5 (0x17)	2 (0x02)
10-MHz	10 (0x12)	2 (0x02)
16-MHz	16 (0x1e)	1 (0x00)
20-MHz	10 (0x12)	1 (0x00)

The 28-bit shift in mode also supports the following features:

- SB (Start Bit detection) is mapped to pru<n>_r31_status[29] and is set when the first 1 is captured on PRU<n>_DATAIN. The SB flag in pru<n>_r31_status[29] is cleared in software through the CFG_GPCFGn registor of the PRU-ICSS CFG register space.
- CNT_16 (Shift Counter) is mapped to pru<n>_r31_status[28] and is set on every 16 shift clock samples after the Start Bit has been received.CNT_16 is self clearing and is connected to the PRU-ICSS INTC. See Section 30.4.2,*Interrupt Controller (INTC)*, for more details.

Figure 30-8. PRU R31 (GPI) 28-Bit Shift In Mode



30.4.1.2.4 General-Purpose Outputs (R30): Enhanced PRU GP Module

The PRU-ICSS implements an enhanced General Purpose Input Output (GPIO) module that supports two general-purpose output modes: direct output and shift out.

Table 30-13 describes these modes in detail.

NOTE: Note, each PRU core can only be configured for one GPO mode at a time. Each mode uses the same R30 signals and internal register bits for different purposes. A summary is found in Table 30-13.

NOTE: The GPCFGn register, bit PR1_PRU0_GP_MUX_SEL in the PRU-ICSS CFG register space needs to be set to 0x0 for GP mode. For a given PRU core, the following IO modes are mutually exclusive: GP mode, Sigma Delta mode, and Peripheral I/F mode.

Table 30-13. PRU R30 (GPO) Output Mode

Mode	Function	Configuration
Direct output	pru<n>_r30[0:31] feeds directly to GPO[0:31]	Default mode
Shift Out	• pru<n>_r30[0] is shifted out on DATAOUT on every rising edge of pru<n>_r30[1] (CLOCKOUT). • LOAD_GPO_SH0 (Load Shadow Register 0) is mapped to pru<n>_r30[29]. • LOAD_GPO_SH1 (Load Shadow Register 1) is mapped to pru<n>_r30[30]. • ENABLE_SHIFT is mapped to pru<n>_r30[31].	Enabled by CFG_GPCFGn register

---

NOTE: Some devices may not pin out all 32 bits of R30. For which pins are available on this device, see Section 30.2.3, *PRU-ICSS Pin List*. See the device data sheet for device-specific pin mapping.

Note: R30 may not be initialized after reset. To avoid outside effect, R30 should be initialized before PINMUX configuration.

pr<k>_pru<n>_gpo28	GPO28	
pr<k>_pru<n>_gpo29	GPO29	
pr<k>_pru<n>_gpo30	GPO30	
pr<k>_pru<n>_gpo31	GPO31	

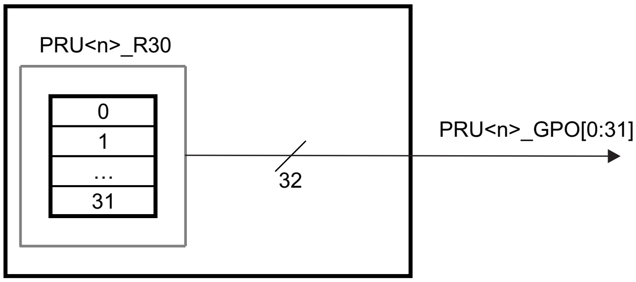
(1) These pins are also used for Sigma Delta or Peripheral I/F mode.

(2) Some devices may not pin out all 30 bits of R31. For which pins are available on this device, see Section 30.2.3, PRU-ICSS Pin List. See the device data sheet for device-specific pin mapping.

30.4.1.2.4.1 Direct Output

The pru<n>_r30 [0:31] bits of the internal PRU register files are mapped to device-level, general-purpose output pins (PRU<n>_GPO[0:31]). In GPO Direct Output mode, pru<n>_r30[0:31] feed directly to PRU<n>_GPO[0:31]. There are 32 possible general-purpose outputs for each PRU core; however, some devices may not pin out all of these signals. See the device-specific data sheet for device-specific pin mapping.

Figure 30-9. PRU R30 (GPO) Direct Output Mode Block Diagram



NOTE: R30 is not initialized after reset. To avoid unintended output signals, R30 should be initialized before pinmux configuration of PRU signals.

30.4.1.2.4.2 Shift Out

In shift out mode, data is shifted out of pru<n>_r30[0] (on PRU<n>_DATAOUT) on every rising edge of pru<n>_r30[1] (PRU<n>_CLOCKOUT). The shift rate is controlled by the effective divisor of two cascaded dividers applied to the ocp_clk. These cascaded dividers can each be configured through the PRU-ICSS CFG register space to a value of {1, 1.5, …, 16}. Table 30-15 shows sample effective clock values and the divisor values that can be used to generate these clocks. Note that the shift out clock is a free-running clock that is always running internally. This clock will be output to PRU<n>_CLOCKOUT (or pr <k>_pru<n>_pru_r30_1) when the PRU GPO mode is set to shift out mode.

Table 30-15. Effective Clock Values

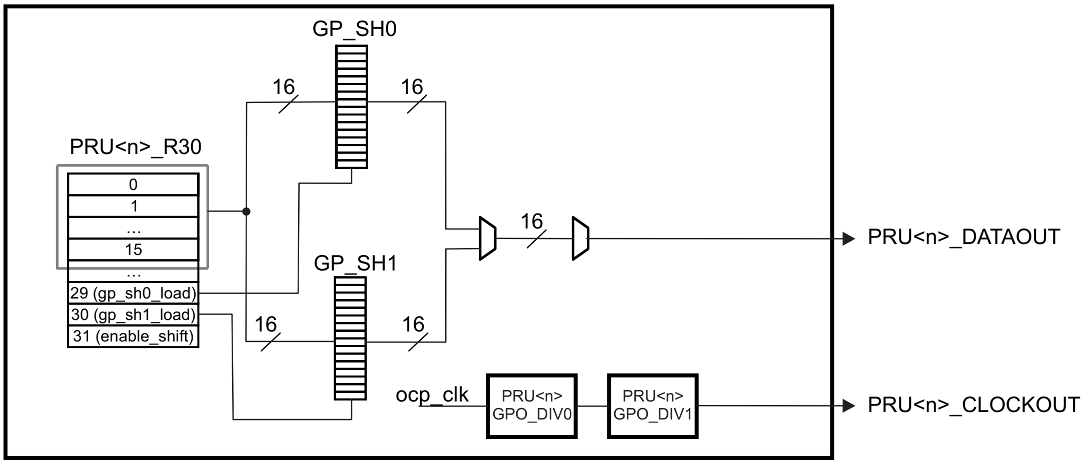
Generated Clock	PRU<n>_GPO_DIV0	PRU<n>_GPO_DIV1
8 MHz	12.5 (0x17)	2 (0x02)
10 MHz	10 (0x12)	2 (0x02)
16 MHz	16 (0x1e)	1 (0x00)
20 MHz	10 (0x12)	1 (0x00)

Shift out mode uses two 16-bit shadow registers (gpo_sh0 and gpo_sh1) to support ping-pong buffers. Each shadow register has independent load controls programmable through pru<n>_r30[29:30] (PRU<n>_LOAD_GPO_SH [0:1]). While PRU<n>_LOAD_GPO_SH [0/1] is set, the contents of pru<n>_r30[0:15] are loaded into gpo_sh0/1.

NOTE: If any device-level pins mapped to pru<n>_r30[2:15] are configured for the pru<n>_r30 [2:15] pinmux mode, then these pins will reflect the shadow register value written to pru<n>_r30. Any pin configured for a different pinmux setting will not reflect the shadow register value written to pru<n>_r30.

The data shift will start from the lsb of gpo_sh0 when pru<n>_r30[31] (PRU<n>_ENABLE_SHIFT) is set. Note that if no new data is loaded into gpo_shn<n> after shift operation, the shift operation will continue looping and shifting out the pre-loaded data. When PRU<n>_ENABLE_SHIFT is cleared, the shift operation will finish shifting out the current shadow register, stop, and then reset.

Figure 30-10. PRU R30 (GPO) Shift Out Mode Block Diagram



Follow these steps to use the GPO shift out mode:

Step One: Initialization

1. Load 16-bits of data into gpo_sh0:
   - i. Set R30[29] = 1 (PRU<n>_LOAD_GPO_SH0)
   - ii. Load data in R30[15:0]
   - iii. Clear R30[29] to turn off load controller
2. Load 16-bits of data into gpo_sh1:
   - i. Set R30[30] = 1 (PRU<n>_LOAD_GPO_SH1)
   - ii. Load data in R30[15:0]
   - iii. Clear R30[30] to turn off load controller
3. Start shift operation:
   - i. Set R30[31] = 1 (PRU<n>_ENABLE_SHIFT)

Step 2: Shift Loop:

1. Monitor when a shadow register has finished shifting out data and can be loaded with new data:
   - i. Poll PRU<n>_GPI_SH_SEL bit of the GPCFG<n> register
   - ii. Load new 16-bits of data into gpo_sh0 if PRU<n>_GPI_SH_SEL = 1
   - iii. Load new 16-bits of data into gpo_sh1 if PRU<n>_GPI_SH_SEL = 0
2. If more data to be shifted out, loop to Shift Loop
3. if there's not more data to be shifted out, exit loop

Step 3: Exit:

1. End shift operation:
   - i. Clear R30[31] to turn off shift operation

NOTE: Until the shift operation is disabled, the shift loop will continue looping and shifting out the pre-loaded data if no new data has been loaded into gpo_sh<n>.

30.4.1.2.5 Sigma Delta (SD) Decimation Filtering H/W

Sigma-delta Sinc filtering is achieved by the combination of PRU hardware and firmware. PRU hardware provides hardware integrators that do the accumulation part of Sinc filtering, while the differentiation part is done in firmware.

The integrator serves to count the number of 1’s per clock event. Each channel has three cascaded counters, which are the accumulators for the Sinc3 filter. Each counter is 24 bits, giving a maximum count of 16,777,215. Each channel has a free running rollover clock counter. This sample counter updates the count value on the effective clock event for that channel. Each channel also contains a programmable counter compare block, and the compare register has a size of 8 bits. However, the minimum value is 4 and maximum value is 202 due to the 24-bit accumulator. Once sample counter compare value is reached, the shadow register copy is updated and the shadow register copy flag is set.

Features of the integrators in PRUs SD Demodulator:

- Up to nine channels with concurrent counting
- Flexible clock source configuration for each channel; option of independent clock source for each channel or one clock source for three channels
- Programmable, 8-bit sample counter compare register; used to set the OSR of Sinc filter
- Three 24-bit cascaded counters per channel for accumulation, only Sinc3 and Sinc2 modes supported
- Common channel enable (all channels are active or none are active)

30.4.1.2.5.1 Block Diagram and Signals

The Sigma Delta’s I/Os are multiplexed with the PRU GPI/GPO signals, as shown in Table 30-17. Note the PR<k>_PRU<n>_GP_MUX_SEL bitfield in the GPCFG<n> register must be set to 0x3 for configure the GPI/GPO signals for SD mode.

Table 30-16. PRU GPI Signals and Configurations for Sigma Delta

Pad Names at Device Level(1)(2)	Sigma Delta (SD) Mode (GPCFGn[PR1_PRUn_GP_MUX_SEL] = 0x3)

pr<k>_pru<n>_gpi24	

(1) Note these signals are shared with the GP and Peripheral I/Fs. To configure for Sigma Delta, GPCFGn[PR1_PRU0_GP_MUX_SEL] needs to be set to 0x3 for SD mode.

(2) NOTE: Some devices may not pin out all 32 bits of R30. For which pins are available on this device, see Section 30.2.3, PRU-ICSS Pin List. See the device data sheet for device-specific pin mapping.

Table 30-16. PRU GPI Signals and Configurations for Sigma Delta (continued)

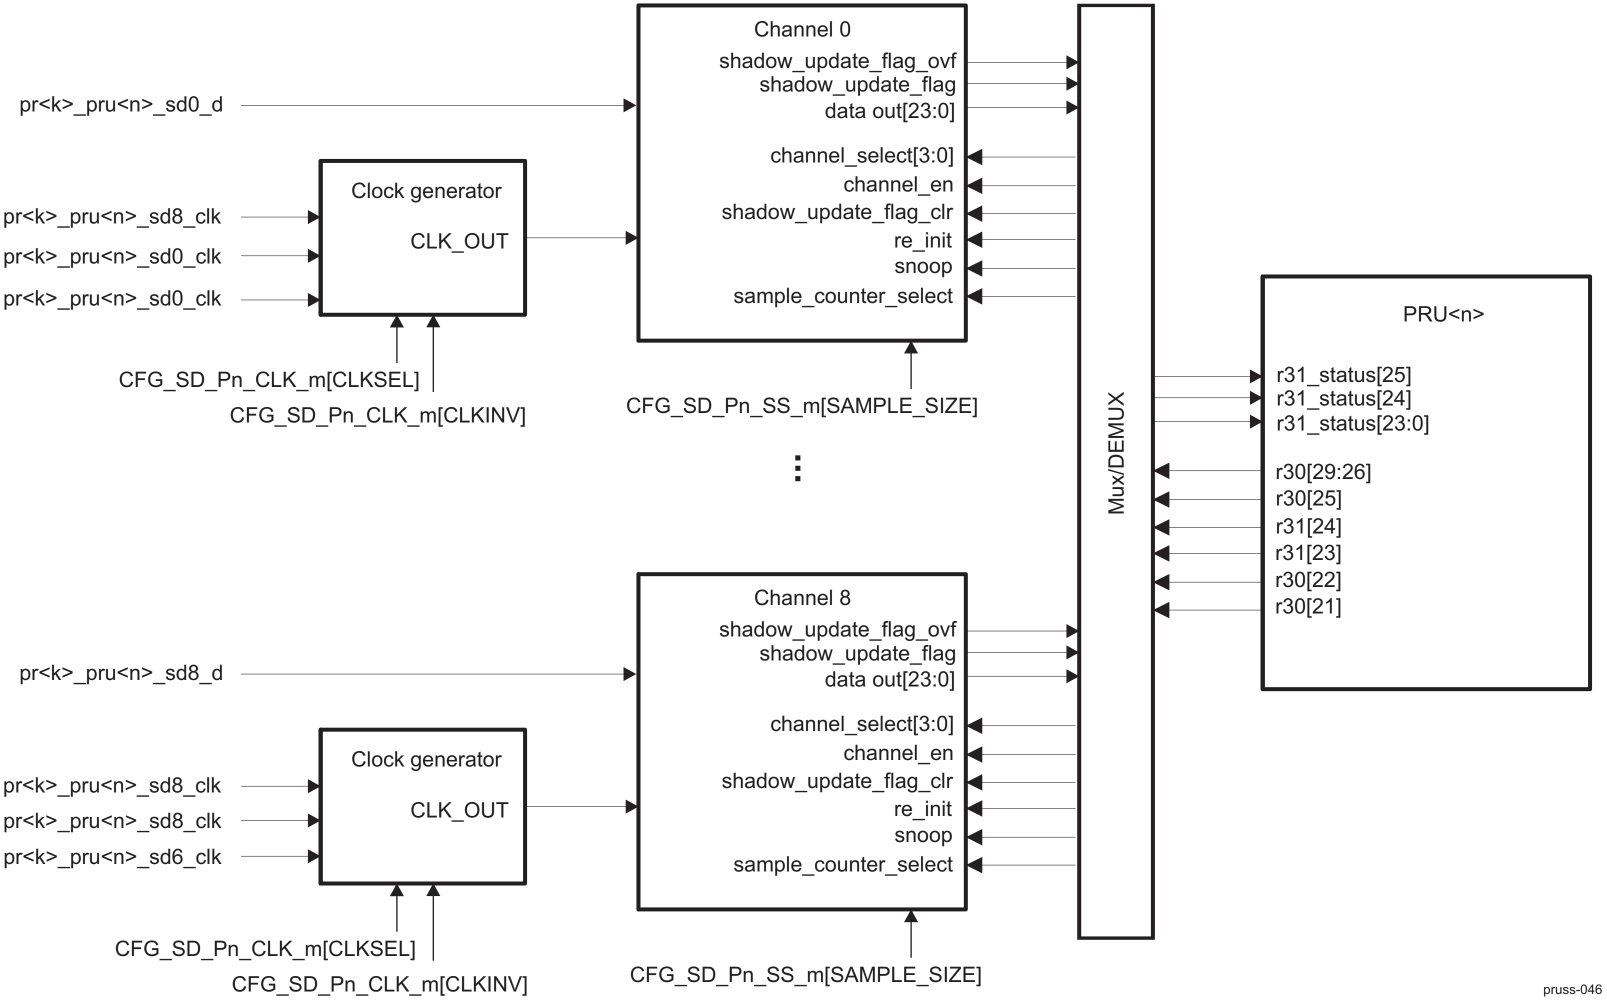
pr<k>_pru<n>_gpi27	
pr<k>_pru<n>_gpi28	
pr<k>_pru<n>_gpi29	

The pr<k>_pru0_gpo1 signal (muxed with SD0_D) can be used as SD_CLKOUT when PRU-ICSS generates clock. This is a trade-off as PRU application will lose one SD channel. SD_CLKOUT needs to go through a clock generator chip if driving multiple sigma delta modulators and also be looped back into PRU-ICSS as SD_CLKIN, typically pru_gpi16.

Note to output the SD clock on pr<k>_pru0_gpo1, this device requires that the PRU core be configured for SD and shift out mode (CFG_GPCFG<n> [PR1_PRU<n>_GP_MUX_SEL] = 0x3 and CFG_GPCFG<n> [PRU<n>_GPO_MODE] = 0x1). Be sure to configure the shift out mode's clock divisors before enabling shift out mode (CFG_GPCFG<n> [PRU<n>_GPO_MODE] = 0x1). Additionally, the PRU-ICSS0 PRU0 SD clock is routed to both pr0_pru0_gpo1 and pr0_pru1_gpo1. Figure 30-11 shows a block diagram of the Sigma Delta implementation. Full description of the PRU R30 and R31 registers are shown in Table 30-18 and Table 30-19.

Figure 30-11. Sigma Delta Block Diagram



Note each channel can independently be configured to use one of three external clock sources. Table 30-17 shows the clock source options, selectable through CFG_SD_P<n>_CLK_<m> [CLKSEL].

Table 30-17. External Clock Sources

CLKSEL value	Clock Source
0	pru<n>_sd8_clk
1	pru<n>_sd<m>_clk
2	pru<n>_sd0_clk for sd0, sd1, and sd2; pru<n>_sd3_clk for sd3, sd4, and sd5; pru<n>_sd6_clk for sd6, sd7, and sd8

30.4.1.2.5.2 PRU R30 / R31 Interface

The PRU uses the R30 and R31 registers to interface with the Sigma Delta interface. Table 30-17 shows the R31 and R30 interface for the Sigma Delta mode. Note that only the parameters and data for one channel can be viewed at a time. The channel to be viewed is determined by the r30[29-26] (channel_select).

Table 30-18. PRU R31: SD Output Interface
Delta Sigma PRU registers: R31Sigma Delta PRU Registers: R31

Bits	Field Name	Description
29-26	Reserved	
25	shadow_update_flag_ovf / shadow_update_flag_ovf_clr	Shadow update flag overflow, set when over sample count equals over sample size and shadow_update_flag is still set. Set this bit to clear the flag.
24	shadow_update_flag / shadow_update_flag_clr	Shadow update flag overflow, set when over sample count equals over sample size and shadow_update_flag is still set. Set this bit to clear the flag.
23	re_init/data_out[23]	re_init (write): Set to reset all counters, flags, and shadow copy. Updates over_sample_size based on the current PRU_ICSS_CFG_SD_P<n>_SS<i> register on the selected channel. data_out[23](read): most-significant bit of sample data
22-0	data_out[22:0]	Selected sample data excluding most-significant bit

25	channel_en	Global Channel enable (effects all 9 channels). 0x0 = All channels disabled. Counters/flags are cleared. 0x1 = All channels enabled.
24-23	Reserved	
22	snoop	Enable snoop (i.e. fetch data) on the selected channel. 0x0 = acc2/acc3 shadow copy 0x1 = current acc2/acc3
21	sample_counter_select	Read sample counter. 0x0 = Not selected 0x1 = Sample count selected

Table 30-19. PRU R30: SD Input Interface Delta Sigma PRU registers: R30Sigma Delta PRU Registers: R30 (continued)

Bits	Field Name	Description
20-0	Reserved	

The PRU_ICSS CFG register space has additional MMRs for controlling the SD demodulator module:

- CFG_SD_P<n>_CLKSEL_<m> [acc2_sel] - Selects accumulator 2 as source
- CFG_SD_P<n>_CLKSEL_<m> [clk_inv] - Inverts clock
- CFG_SD_P<n>_CLKSEL_<m> [clk_sel] - Selects clock source
- CFG_SD_P<n>_SS_<m> [sample_size] - Selects number of samples to read before giving output

30.4.1.2.5.3 Sigma Delta Description

Figure 30-12 shows a block diagram of the Sigma Delta hardware integrators and integration with the PRU R30 / R31 interface for a single channel.

Figure 30-12. Sigma Delta Hardware Integrators Block Diagram (snoop = 0)

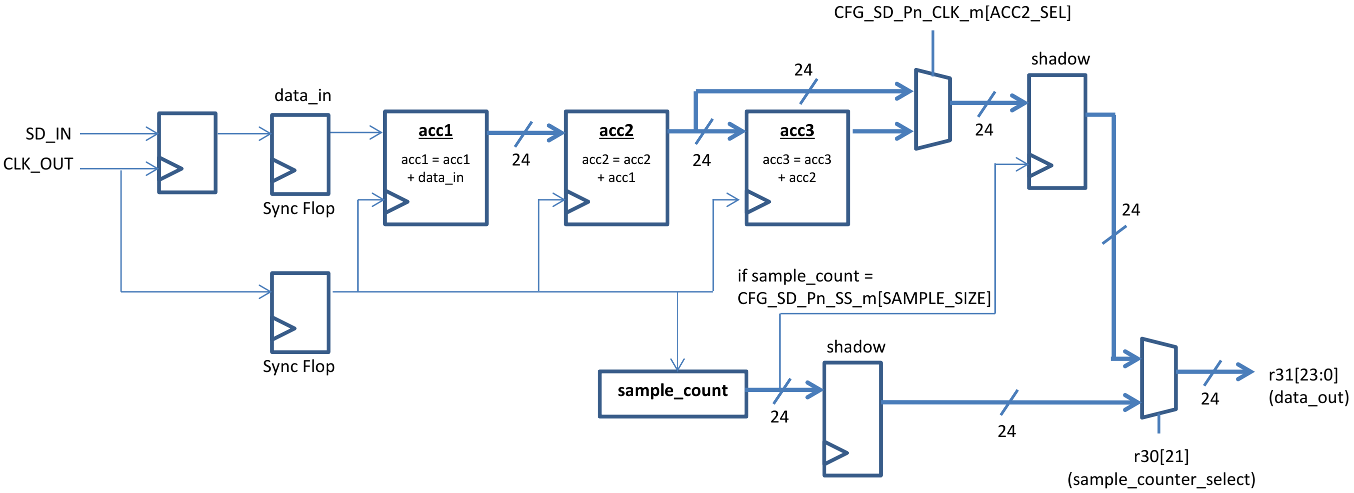

Figure 30-13. Sigma Delta Hardware Integrators Block Diagram (snoop = 1)

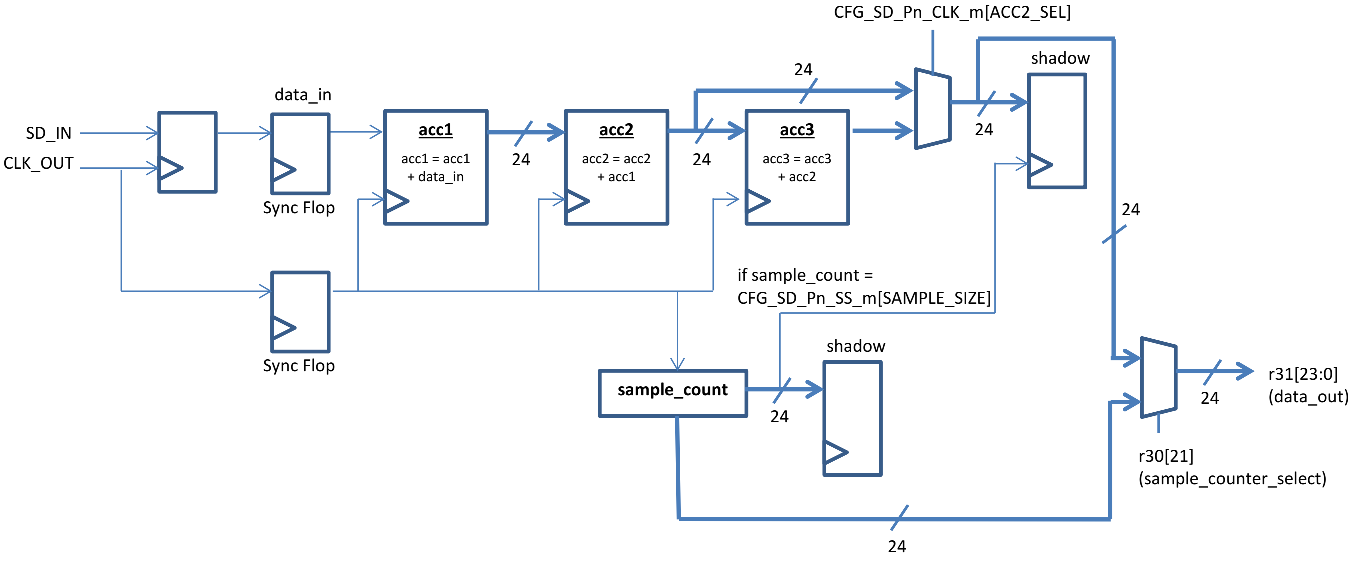

The three accumulators (acc1-acc3) for each channel are simple 24 bit adders. The input for acc1 is 1-bit, while the inputs for acc2 and acc3 are 24-bits. On each positive edge of the CLK_OUT, all three 24-bit counters (acc1-acc3) and the sample counter for each channel will get updated as follows:

```
acc1 = acc1 + data_in
acc2 = acc2 + acc1
acc3 = acc3 + acc2
sample_count = sample_count + 1
```

Each accumulator will rollover at 0xFF_FFFF. For example if acc2 = 0x10 and acc3 = 0xFF_FFFF, then acc3 will update to 0x00_0000F on the next clock event. Sample_count will rollover when it equals the defined sample size (CFG_SD_P<n>_SS_<m> [sample_size]).

Note that while the channels are not enabled , no operations are performed and all flags and counters are cleared. If a new sample size is to be loaded, the PRU firmware should assert re_init (r31[23]), and all stored count values are cleared to 0.

The Sigma Delta interface has two status flags:

- Shadow update flag (r31[24])
- Shadow update flag overflow (r31[25])

When sample_count equals the defined sample size (CFG_SD_P<n>_SS_<m> [sample_size]), then the acc2/acc3 shadow register copy will be updated, the shadow_update_flag (r31[24]) will be set, and sample_count will rollover to 0. The PRU firmware can clear this flag by writing ‘1’ to shadow_update_flag_clr (r31[24]). If sample_count equals the defined sample size and the shadow_update_flag is still set, then shadow_update_flag_ovf (r31[25]) will be set. Similarly, the PRU firmware can clear this flag by writing ‘1’ to shadow_update_flag_ovf_clr (r31[25]). Note that the clear operation for both flags has a higher priority than the set event.

The PRU firmware can monitor the acc2/acc3 and sample_count values through data_out[23:0] (r31[23:0]). Table 30-20 shows the configuration options for data_out[23:0].

Table 30-20. Data_out[23:0] Configuration Options

snoop (r30[22])	sample_counter_select (r30[21])	data_out (r31[23:0])
0	0	Reads acc2/acc3 shadow register copy
1	0	Reads acc2/acc3 directly
0	1	Reads sample_count shadow register copy
1	1	Reads sample_count directly

30.4.1.2.5.4 Basic Programming Example

The following programming example assumes that the PRU is configured for Sigma Delta Mode (CFG_GPCFG<n> [PR1_PRU<n>_GP_MUX_SEL] = 3).

1. Configure clock sources, accumulator source, and sample size:
    a. CFG_SD_P<n>_CLKSEL_<m> [clk_sel] for clock source
    b. CFG_SD_P<n>_CLKSEL_<m> [clk_inv] for clock polarity
    c. CFG_SD_P<n>_CLKSEL_<m> [acc2_sel] for accumulator source
    d. CFG_SD_P<n>_SS_<m> [sample_size] for sample size
2. Reinitialize all channels whose sample size was configured
    a. Select channel by writing to channel_select (r30[29-26])
    b. Delay at least 1 PRU cycle before executing re_int in step 2c.
    c. Reinitialize selected channel by writing to re_init (r31[23])
    d. Repeat steps 2a & 2b for all configured channels
3. Enable all channels by writing ‘1’ to channel_en (r30[25])
4. Select channel by writing to channel_select (r30[29-26])
    a. Poll shadow_update_flag (r31[24]) to detect when acc2/acc3 shadow register copy data is ready to

be ready

   b. Delay at least 1 PRU cycle before polling shadow_update_flag in Step 4c.
   c. Read data_out[23:0] (r31[23:0])
   d. Clear shadow_update_flag by writing ‘1’ to r31[24]

5. Repeat step 4 for new channel

30.4.1.2.6 Peripheral Interface

The Peripheral Interface supports functionality for operations utilizing protocols like EnDat 2.2 and BiSS.

This module supports the following features:

- 3 channels with baud range from 100 kHz to 16 MHz
- uart_clk (default) or ocp_clk master clock is an input to independent div16fr clock dividers to produce a 1X clock (ENDAT<m>_CLK) and oversampling clock
- Half-duplex (TX and RX are not supported concurrently)
- TX FIFO size of 32 bits
- RX FIFO size of 32 bits
- Configurable shift size/oversampling on RX
- Optional RX frame size auto shut off
- Programmable HW delay 1 (wire delay, controlling when the clock signal is first driven low) and delay 2 (tst delay, controlling when the clock signal is first driven high) on TX operation
- Optional programmable TX termination
- Individual TX channel start trigger (tx_channel_go) or simultaneous TX start trigger for all channels (tx_global_go)
- Flexible HW assisted clock output generation to allow free running, stop high and stop low (after last RX data), or stop high (after last TX data) operation with optional software clock override feature
- Optional SW direct snoop of data input

30.4.1.2.6.1 Block Diagram and Signal Configuration

The Peripheral Interface’s I/Os are multiplexed with the PRU GPI/GPO signals, as shown in Table 30-21. The PR<k>_PRI<n>_GP_MUX_SEL bitfield in the GPCFG<n> register must be set to 0x1 for configure the GPI/GPO signals for Peripheral I/F mode.

Table 30-21. PRU GPI/GPO Signals and Configurations for Peripheral I/F(1)

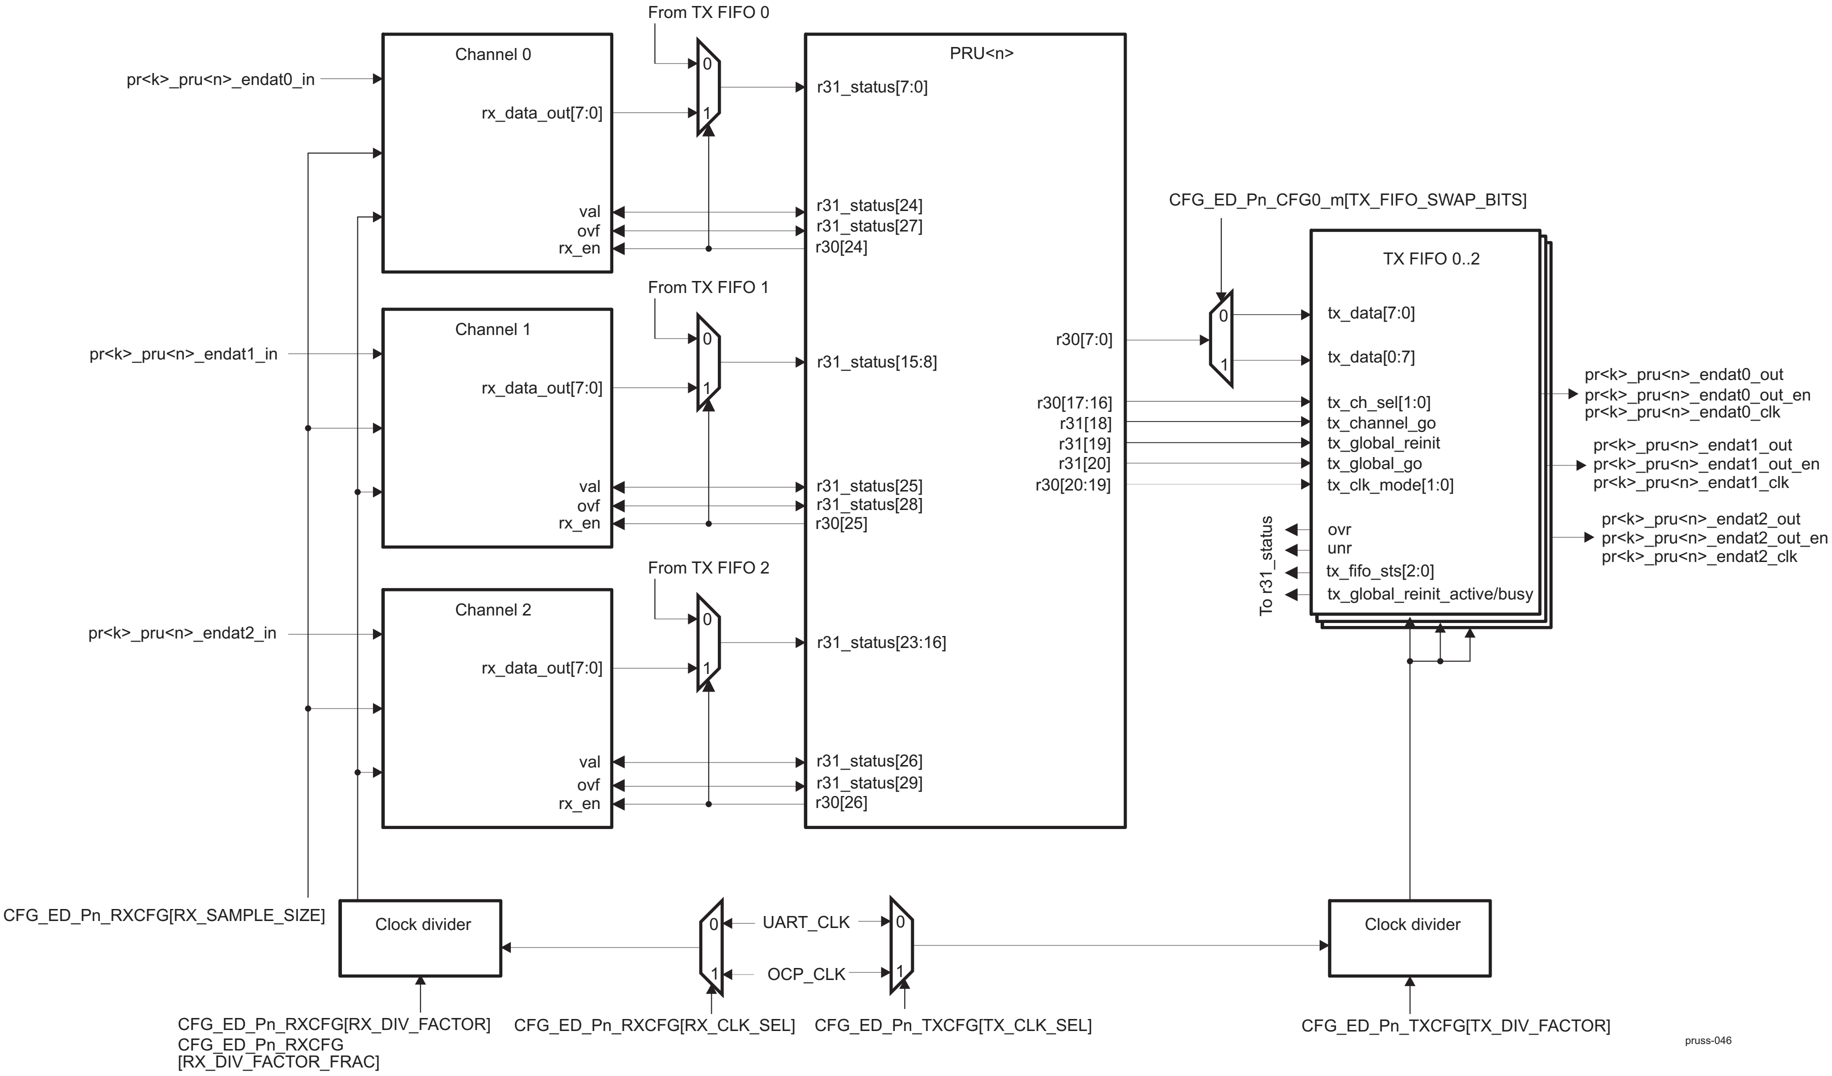
A block diagram for the Peripheral I/F is included in Figure 30-14. As shown, each channel is composed of four I/Os:

- ENDAT<m>_IN - RX input data
- ENDAT<m>_CLK - Clock (CLK_OUT) generated by the 1x (or TX) clock. The default value is 1.
- ENDAT<m>_OUT - TX output data. The default value is 0.
- ENDAT<m>_OUT_EN - TX enable output (1 = TX mode, 0 = RX mode). The default value is 0. Note this signal is auto controlled by hardware.

Figure 30-14. Peripheral I/F Block Diagram



30.4.1.2.6.2 PRU R30 and R31 Interface

The PRU uses the R30 and R31 registers to interface with the Peripheral I/F. Table 30-22 shows the R31 and R30 interface for the Peripheral I/F RX mode, and Table 30-23 shows the comparable interface for the TX mode.

Table 30-22. Peripheral I/F: RX

Register	Bits	Field Name	Description
R31	31-30	Reserved	PRU Host Interrupts 1/0 from local INTC
	29	ovf2	Overflow Flag for Channel 2. Write 1 to clear.
	28	ovf1	Overflow Flag for Channel 1. Write 1 to clear.
	27	ovf0	Overflow Flag for Channel 0. Write 1 to clear.
	26	val2	Valid Flag for Channel 2. Write 1 to clear.
	25	val1	Valid Flag for Channel 1. Write 1 to clear.
	24	val0	Valid Flag for Channel 0. Write 1 to clear.
	23-16	rx_data_out2	Oversampled Data Output for Channel 2. Note these bits are shared with the TX Interface. When TX_FIFO has stopped transmission, RX data will be selected.
	15-8	rx_data_out1	Oversampled Data Output for Channel 1. Note these bits are shared with the TX Interface. When TX_FIFO has stopped transmission, RX data will be selected.
	7-0	rx_data_out0	Oversampled Data Output for Channel 0. Note these bits are shared with the TX Interface. When TX_FIFO has stopped transmission, RX data will be selected.
R30	31-27	Reserved	
	26	rx_en2	RX Enable for Channel 2. 0: Channel not enabled, all counters/flags will get reset 1: Channel is enabled
	25	rx_en1	RX Enable for Channel 1. 0: Channel not enabled, all counters/flags will get reset 1: Channel is enabled
	24	rx_en0	RX Enable for Channel 0. 0: Channel not enabled, all counters/flags will get reset 1: Channel is enabled
	23-0	Reserved

Register	Bits	Field Name	Description
R31	31-30	Reserved	
	29:22	Reserved	
	21	tx_global_reinit_active/busy2	If tx_global_reinit has been set, this status shows if the reinit has been complete. 1 = Active 0 = Done If tx_global_reinit has not been set, this status shows if the last bit is on the TX wire (i.e. ENDAT<m>_OUT). Note it does not mean the clock is off. 1 = Last bit is not done 0 = Last bit on tx wire Note that by using RX auto arm feature (i.e. CFG_ED_P<n>_CFG1_<m> [RX_EN_COUNTER] > 0), the observation of tx_global_reinit_active/busy is lost when rx_en<m> = 1. However, tx_global_reinit_active/busy can be used to determine when to enable RX during non-auto arm case.
	20	tx_global_go	TX global start of all channels. Note: FIFO must not be empty. If empty, transmit will not start.
	19	tx_global_reinit	Reinit all channels into default mode. This clears all flags and state machines for all channels. Note: Sequence should be assert tx_global_reinit then de-assert rx_en. This will ensure TX and RX are in reset/default state. User must assert this after the frame has been sent and TX is not busy.
	18	tx_channel_go	TX start the channel transmit (selected by tx_ch_sel). Note: FIFO must not be empty.
	17	unr2	Under Run Flag for Channel 2. This flag is only set when the tx_frame_count is nonzero and FIFO is empty at time to send data.
	16	ovr2	Over Run Flag for Channel 2
	15-14	Reserved	
	13	tx_global_reinit_active/busy1	If tx_global_reinit has been set, this status shows if the reinit has been complete. 1 = Active 0 = Done If tx_global_reinit has not been set, this status shows if the last bit is on the TX wire (i.e. ENDAT<m>_OUT). Note it does not mean the clock is off. 1 = Last bit is not done 0 = Last bit on tx wire Note that by using RX auto arm feature (i.e. CFG_ED_P<n>_CFG1_<m> [RX_EN_COUNTER] > 0), the observation of tx_global_reinit_active/busy is lost when rx_en<m> = 1. However, tx_global_reinit_active/busy can be used to determine when to enable RX during non-auto arm case.
	12:10	tx_fifo_sts1	TX FIFO occupancy status for Channel 1 0 = Empty 1 = 1 word 2 = 2 words 3 = 3 words 4 = Full 5-7 = Reserved
	9	unr1	Under Run Flag for Channel 1. This flag is only set when the tx_frame_count is nonzero and FIFO is empty at time to send data.
	8	ovr1	Over Run Flag for Channel 1
	7:6	Reserved	

Table 30-23. Peripheral I/F: TX (continued)

Register	Bits	Field Name	Description
R31	5	tx_global_reinit_active/busy0	If tx_global_reinit has been set, this status shows if the reinit has been complete. 1 = Active 0 = Done If tx_global_reinit has not been set, this status shows if the last bit is on the TX wire (i.e. ENDAT<m>_OUT). Note it does not mean the clock is off. 1 = Last bit is not done 0 = Last bit on tx wire Note that by using RX auto arm feature (i.e. CFG_ED_P<n>_CFG1_<m> [RX_EN_COUNTER] > 0), the observation of tx_global_reinit_active/busy is lost when rx_en<m> = 1. However, tx_global_reinit_active/busy can be used to determine when to enable RX during non-auto arm case.
	4:2	tx_fifo_sts0	TX FIFO occupancy status for Channel 0 0 = Empty 1 = 1 word 2 = 2 words 3 = 3 words 4 = Full 5-7 = Reserved
	1	unr0	Under Run Flag. This flag is only set when the tx_frame_count is nonzero and FIFO is empty at time to send data.
	0	ovr0	Over Run Flag for Channel 0

Table 30-23. Peripheral I/F: TX (continued)

Register	Bits	Field Name	Description
R30	31:21	Reserved	
	20:19	clk_mode	CLK_OUT mode. 0 = Free-running/stop-low. Clock will remain free-running until the receive module has received the number of bits indicated in rx_frame_counter and then the clock will stop low. 1 (default) = Free-running/stop-high. Clock will remain free-running until the receive module has received the number of bits indicated in rx_frame_counter and then the clock will stop high. Note this is the default/reset state, and a hardware reset or reinit will return clk_mode to this state. Note the initial state of the clock will be high, but the clock will not start until TX GO event. 2 = Free-run. NOTE: You must do a reinit to get out of this clock mode then you can update clk_mode to a different mode. Also if you do multiple TX GO, the 2nd go should have tst_delay and wire_delay zero since the clock is free running after the first go. 3= Stop high after transmit. Clock will run until the last TX bit is sent and stops high.
	18	Reserved	
	17:16	tx_ch_sel	TX channel select. 0 = Channel 0 1 = Channel 1 2 = Channel 2 3 = Reserved
	15:9	Reserved	
	7:0	tx_data	TX data for FIFO. Notes: FIFO transmits MSB first and is 32-bits deep. TX_FIFO_SWAP_BITS bit in the PRU-ICSS CFG register space can be used to flip the load order of bits. The FIFO has 2 modes of operation: 1. Preload and Go. This should be done for EnDAT and frames less than 32-bits. 2. Continuous mode. This should be done for frames bigger than 32-bits. In continuous mode, software needs to keep up with the line rate and ensure that the FIFO is never empty. When the FIFO is at 2 byte level, software needs to load the next 2 bytes. If software waits till the end of the empty state, it is possible to get the TX into a bad state. The FIFO state can be recovered via re-init.

30.4.1.2.6.3 Clock Generation

30.4.1.2.6.3.1 Configuration

The Peripheral I/F module has two source clock options, uart_clk (default) and ocp_clk. There are two independent clock dividers (div16) for the 1x and oversampling (OS) clocks, and each clock divider is configurable by two cascading dividers:

- TX_DIV_FACTOR and TX_DIV_FACTOR_FRAC for the 1x clock
- RX_DIV_FACTOR and RX_DIV_FACTOR_FRAC for the OS clock

The 1x clock is output on the ENDAT<m>_CLK signal. In TX mode, the output data is read from the TX FIFO at this 1x clock rate. The default value of this clock is high and the start and stop conditions for this clock are described in Section 30.4.1.2.6.3.2 and Section 30.4.1.2.6.3.3.

In RX mode, the input data is sampled at the OS clock rate. Note the OS clock rate divided by the 1x clock rate must equal RX_SAMPLE_SIZE.

Example clock rates and divisor values relative to the 192-MHz uart_clk clock source are shown in Table 30-24.

Table 30-24. Clock Rate Examples for 192-MHz uart_clk Clock Source

TX_DIV_FACTOR	1x Clock	RX_DIV_FACTOR	RX_DIV_FACTOR_FRAC	OS Clock	Oversample Factor
12	16 MHz	1	1.5	128 MHz	8x
16	12 MHz	2	1	96 MHz	8x
24	8 MHz	3	1	64 MHz	8x
32	6 MHz	4	1	48 MHz	8x
48	4 MHz	6	1	32 MHz	8x
96	2 MHz	12	1	16 MHz	8x
192	1 MHz	24	1	8 MHz	8x

30.4.1.2.6.3.2 Clock Output Start Conditions

This section describes the configurable start conditions for the ENDAT<m>_CLK. The software can completely control via CFG_ED_P_<n>_CFG0_<m> PRUn_EDm_CLK when ED_CLK_OUT_OVERRIDE_EN = 1. By default however, the PRU hardware will control the clocks as described in the following sections.

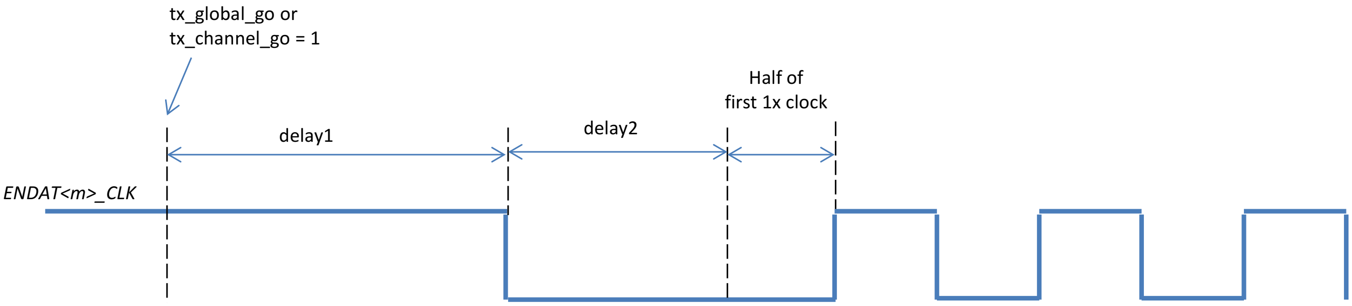
30.4.1.2.6.3.2.1 TX Mode (RX_EN = 0)

In TX mode, the ENDAT<m>_CLK begins after the firmware loads the TX FIFO and sets either r30[20] (tx_global_go) or r30[17:16] (tx_channel_go) to 1. After the “go” bit is set, the delay1 (wire delay) compensation counter for each channel begins. After delay1 is complete, ENDAT<m>_CLK is driven low and then the delay2 (tst) counter begins. After the delay2 counter expires, the ENDAT<m>>_CLK starts running (first low and then high). Therefore, first rising edge of ENDAT<m>_CLK (measured from the go bit) = delay1 (tx wire delay) + delay2 (tst_counter delay) + half of the 1x clock frequency (since the clock starts low).

Figure 30-15 shows the start condition for TX mode. As shown in the figure, the default value of clock is high. The PRU-ICSS CFG register space has additional MMRs for controlling the TX start timing delay values:

- Delay 1: CFG_ED_P<n>_CFG0<m> [TX_WIRE_DLY]
- Delay 2: CFG_ED_P<n>_CFG1<m> [TST_DELAY_COUNTER]

Figure 30-15. TX Mode Start Condition



30.4.1.2.6.3.2.2 RX Mode (RX_EN = 1)

In RX mode, the ENDAT<m>_CLK will start running whenever the RX_EN is set. Note that the PRU firmware in this mode is responsible for any delay conditions.

The hardware can also auto-enable RX mode at the end of a TX transaction. The CFG_ED_P<n>_CFG1<m> [RX_EN_COUNTER] is used to program a delay between the last TX bit sent and when the RX_EN is set.

30.4.1.2.6.3.3 Stop Conditions

The r30[20:19] (clk_mode[1:0]) value determines the stop condition for ENDAT<m>_CLK. There are 4 options available:

clk_mode_value	Description
0	Stop low on last RX frame
1	Stop high on last RX frame
2	Run continuously
3	Stop high on last TX bit

The last RX frame is configured by CFG_ED_P<n>_CFG0_<m> [rx_frame_size], and the last TX bit is configured by CFG_ED_P<n>_CFG0_<m> [tx_frame_size]. Each stop condition is shown in Figure 30-16 through Figure 30-19.

Figure 30-16. ENDAT<m>_CLK Stop High on Last RX Frame

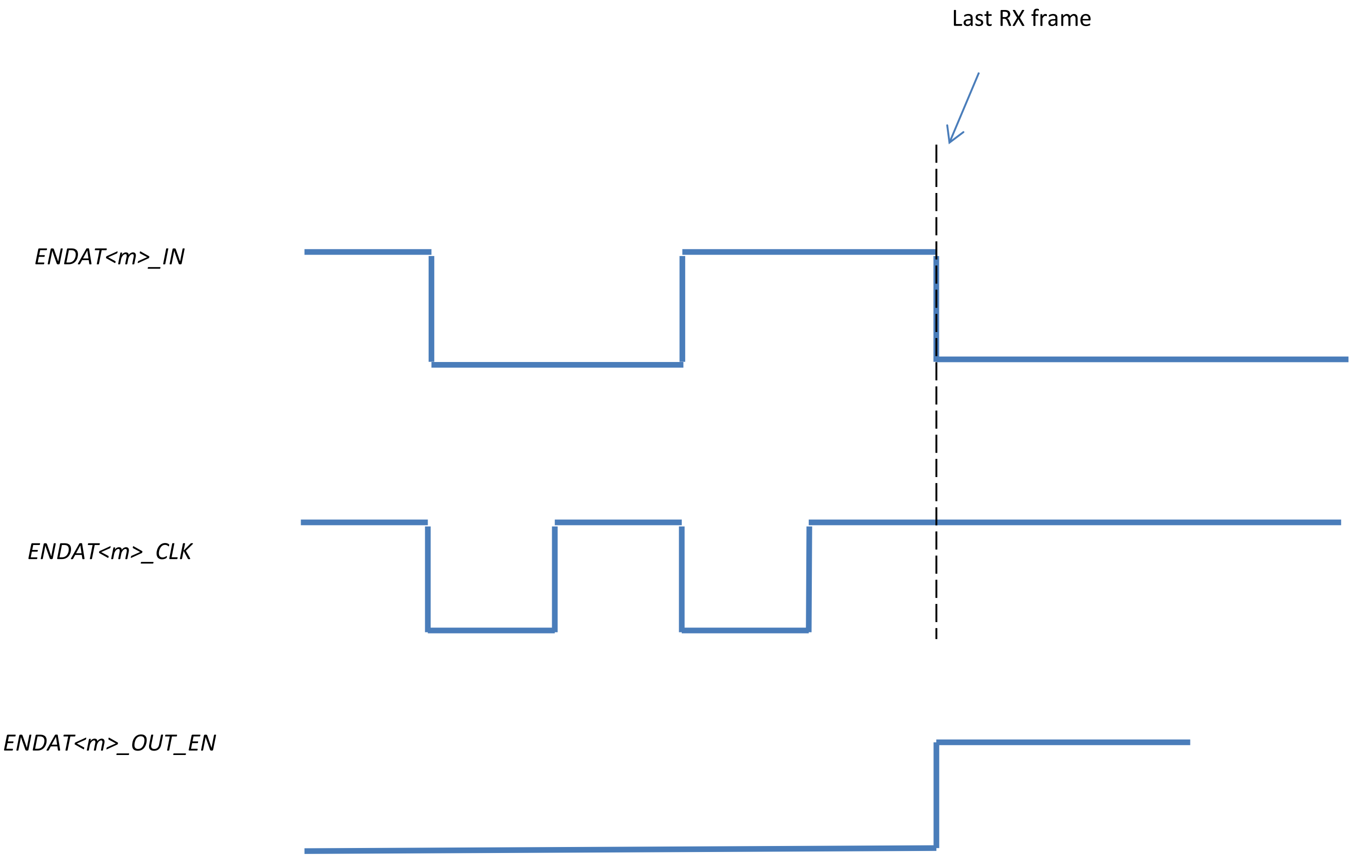


Figure 30-17. ENDAT<m>_CLK Stop Low on Last RX Frame

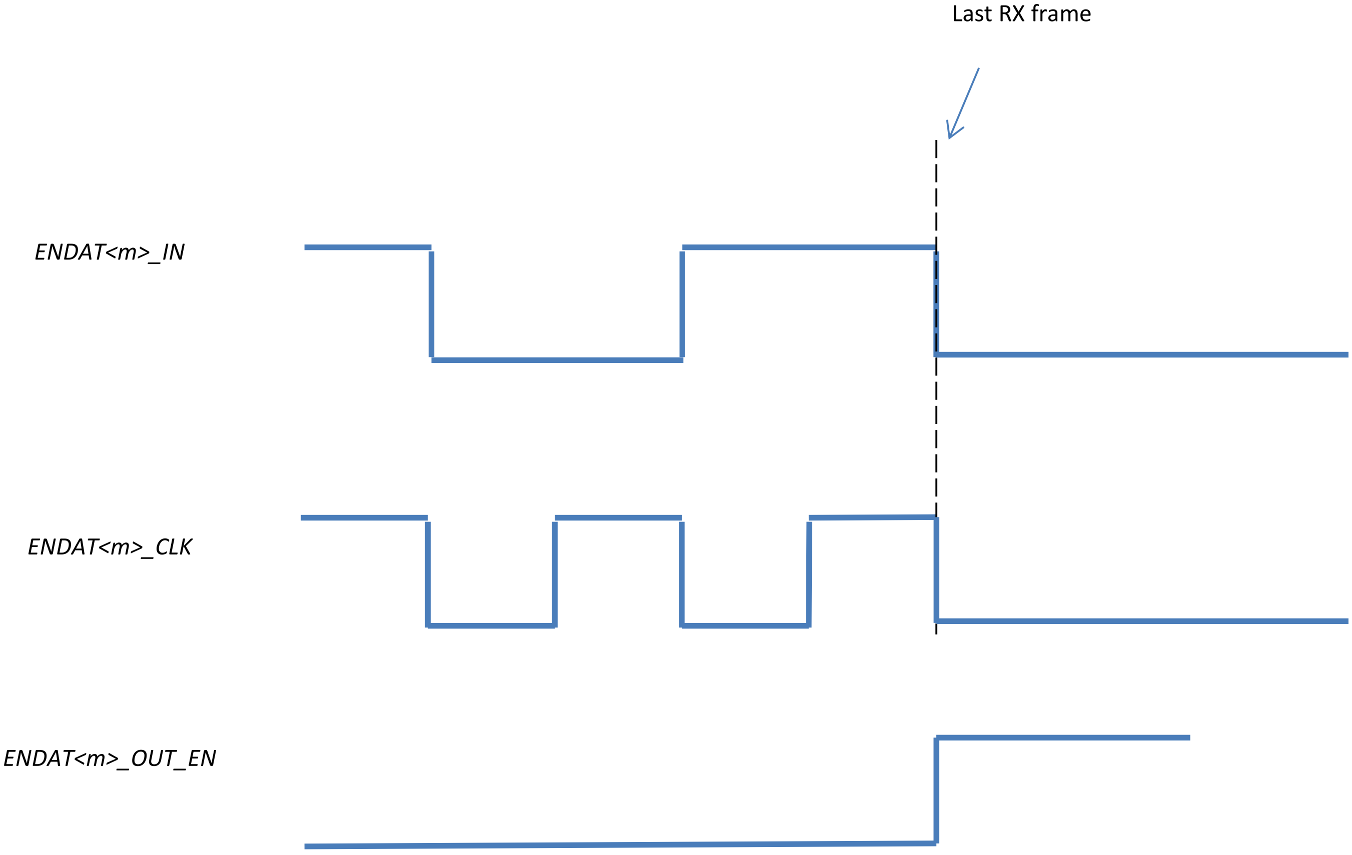

Figure 30-18. ENDAT<m>_CLK Run Continuously

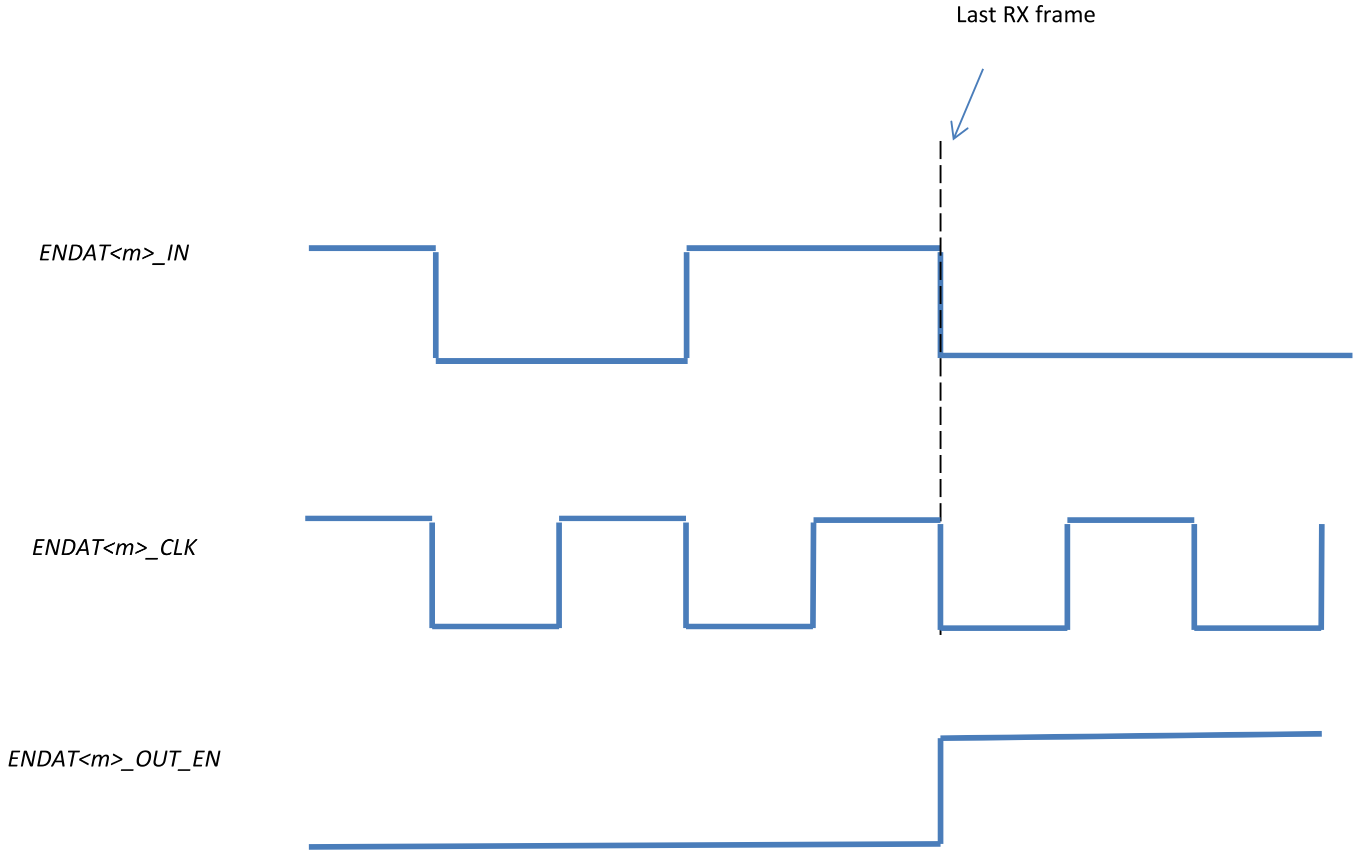

Figure 30-19. ENDAT<m>_CLK Stop High on Last TX Bit

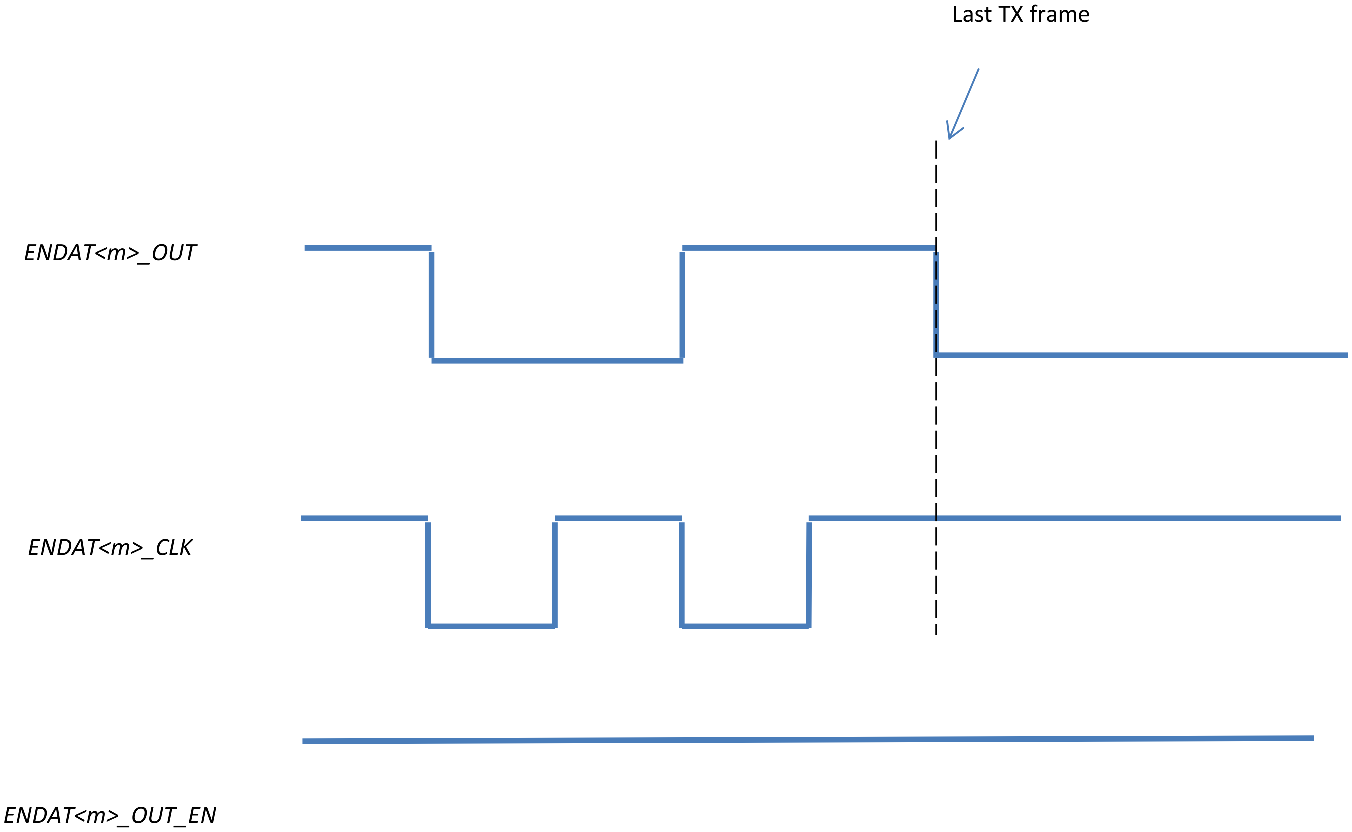


30.4.1.2.6.4 Basic Programming Model

The following programming models assume that the PRU is configured for 3 Peripheral Mode (CFG_GPCFG<n> [PR1_PRI<n>_GP_MUX_SEL] = 1).

30.4.1.2.6.4.1 Clock Generation

Follow these steps to configure Peripheral I/F clocks using the HW control of the clock:

1. Select TX and RX clock sources:
   a. CFG_ED_P<n>TXCFG [TX_CLK_SEL] for the TX clock source
   b. CFG_ED_P<n>RXCFG [RX_CLK_SEL] for the RX clock source
2. Configure the 1x (TX) clock frequency:
   a. Write Division Factor to CFG_ED_P<n>_TXCFG {TX_DIV_FACTOR]
   b. Write Fraction division factor to CFG_ED_P<n>_TXCFG [TX_DIV_FACTOR_FRAC]
3. Configure the oversampling (RX) frequency and oversample size:
   a. Write Division Factor to CFG_ED_P<n>_RXCFG [RX_DIV_FACTOR]
   b. Write Fraction division factor to CFG_ED_P<n>_RXCFG [RX_DIV_FACTOR_FRAC]
   c. Write RX oversample size to CFG_ED_P<n>_RXCFG[RX_SAMPLE_SIZE]
4. Select the clk_mode to configure how the ENDAT<m>_CLK signal ends after TX/RX:
   a. Write to r30[20:19] (clk_mode). Note the clk_mode setting can also be changed per transaction.
5. Configure the wire, tst, and rx_en_counter delay values:
   a. CFG_ED_P<n>_CFG0_<m> [TX_WIRE_DLY] for wire delay
   b. CFG_ED_P<n>_CFG0_<m> [TST_DELAY_COUNTER] for tst delay

c. CFG_ED_P<n>_CFG1_<m> [RX_EN_COUNTER] for auto-delay between TX and RX

30.4.1.2.6.4.2 TX - Single Shot

Follow these steps to configure the Peripheral I/F channel(s) for a single shot transmission:

1. (Optional) Configure TX FIFO for MSB (default) or LSB:
    1. CFG_ED_P<n>_CFG0_<m> [TX_FIFO_SWAP_BITS]
2. Pre-load TX FIFO:
    1. Select TX channel by writing the desired channel number to R30[17:16] (tx_ch_sel)
    2. Write 1-4 bytes of data to r30[7:0] (tx_data). At each r30[7:0] write, data will be pushed into the FIFO.
    3. Repeat Steps 2a and 2b for all desired channels.
3. Configure TX frame size if less than 4 full bytes loaded into FIFO:
    1. CFG_ED_P<n>_CFG0_<m> [TX_FRAME_SIZE]
4. Push TX FIFO data to ENDAT<m>_OUT (see Section 30.4.1.2.6.3.2 for the ENDAT<m>_CLK and ENDAT<m>_OUT start time relationship);
    1. To start TX on all channels, set r31[20] = 1 (tx_global_go).
    2. To start TX on individual channel:
        - i. Select TX channel by writing the desired channel number to R30[17:16] (tx_ch_sel)
        - ii. Set R31[18] = 1 (tx_channel_go)
5. If CFG_ED_P<n>_CFG1_<m> [RX_EN_COUNTER] > 0, then the channel will automatically switch into RX mode. See Section 30.4.1.2.6.4.4 for an example of how to program and configure RX content.
6. If CFG_ED_P<n>_CFG1_<m> [RX_EN_COUNTER] = 0, poll either r31[21, 13, or 5] (tx_global_reinit_active/busy[2,1,0]) or CFG_ED_P<n>_TXCFG [TX_BUSY<m>] for when TX is complete

NOTE: The ENDAT<m>_CLK Peripheral I/F requires that ENDAT<m>_CLK be in a high state at the beginning of a new transaction. If the clock ended the single shot transmission in low state, then the clock needs to be reset before sending more data. The steps to reset ENDAT<m>_CLK are:

1. Set R31[19] = 1 (tx_global_reinit) to reset clock high
2. Wait until tx_busy<m> is cleared
3. Re-configure R30[20:19] (clk_mode), since reinit will reset the clk_mode to "Free-running/stop-high" mode

30.4.1.2.6.4.3 TX - Continuous FIFO Loading

Follow these steps to configure the Peripheral I/F channel(s) for a continuous loading transmission:

1. (Optional) Configure TX FIFO for MSB (default) or LSB:
    - a. CFG_ED_P<n>_CFG0_<m> [TX_FIFO_SWAP_BITS]
2. Pre-load TX FIFO:
    - a. Select TX channel by writing the desired channel number to r30[17:16] (tx_ch_sel)
    - b. Write 1-4 bytes of data to r30[7:0] (tx_data). At each r30[7:0] write, data will be pushed into the FIFO.
    - c. Repeat Steps 2a and 2b for all desired channels.
3. Configure TX frame size to continuously transmit the TX FIFO until empty:
    - a. Set CFG_ED_P<n>_CFG0_<m> [TX_FRAME_SIZE] = 0
4. Push TX FIFO data to ENDAT<m>_OUT (see Section 30.4.1.2.6.3.2 for the ENDAT<m>_CLK and ENDAT<m>_OUT start time relationship):
    - a. To start TX on all channels, set r31[20] = 1 (tx_global_go).

   b. To start TX on individual channel:
      i. Select TX channel by writing the desired channel number to r30[17:16] (tx_ch_sel)
      ii. Set r31[18] = 1 (tx_channel_go)
5. Monitor line rate and reload FIFO:
   a. Polling r31[xx, 12:10, 4:2] (tx_fifo_sts<m>)
   b. When FIFO level is at 2 bytes, load next 2 bytes of data (see Step 2). Do not let the FIFO get close to 0. Once the FIFO runs empty, the hardware will assume the PRU has reached end of the last transmit. Any new writes to the FIFO will NOT be sent until the software sends another tx_channel_go bit. Note there are also underrun and overrun error flags that can be monitored.
6. To end TX operation, do not send any new data to FIFO.
   a. If CFG_ED_P<n>_CFG1_<m> [RX_EN_COUNTER] > 0, then the channel will automatically switch into RX mode. See Section 30.4.1.2.6.4.4 for an example of how to program and configure RX content.
   b. If CFG_ED_P<n>_CFG1_<m> [RX_EN_COUNTER] = 0, poll either r31[21, 13, or 5] (tx_global_reinit_active/busy[2,1,0]) or CFG_ED_P<n>_TXCFG [TX_BUSY<m>] for when TX is complete

NOTE: The ENDAT<m>_CLK Peripheral I/F requires that ENDAT<m>_CLK be in a high state at the beginning of a new transaction. If the clock ended the continuous loading transmission in low state, then the clock needs to be reset before sending more data. The steps to reset ENDAT<m>_CLK are:

1. Set R31[19] = 1 (tx_global_reinit) to reset clock high
2. Wait until tx_busy<m> is cleared
3. Re-configure R30[20:19] (clk_mode), since reinit will reset the clk_mode to "Free-running/stop-high" mode

30.4.1.2.6.4.4 RX - Auto Arm or Non-Auto Arm

Follow these steps to configure the Peripheral I/F channel(s) to receive data:

1. Configure RX and frame size:
   a. CFG_ED_P<n>_CFG_<m> [RX_FRAME_SIZE]
2. To start ENDAT<m>_CLK:
   a. For the non-auto arm use case, set r30[26, 25, 24] = 1 (rx_en<m>)
   b. For the auto arm use case, rx_en<m> will be automatically enabled at the end of a TX operation when CFG_ED_P<n>_CFG1_<m> [RX_EN_COUNTER] > 0
3. RX FIFO will start filling on the first start bit (ENDAT<m>_IN = 1). The data will be captured on the positive edge of the ENDAT<m>_CLK and shifted into the LSB position of the 8-bit shadow register.
4. Poll for r31[26, 25, 24] (val<m>) assertion. The valid flag will be asserted when n bits of data (determined by CFG_ED_P<n>_RXCFG [RX_SAMPLE_SIZE]) have been collected.
5. Fetch data by reading r31[23-16, 15-8, 7-0] (rx_data_out<m>). The data will remain constant for one data frame, and PRU must read data and clear valid flag within this time. Otherwise, an overflow will occur – r31[29, 28, 27] (ovf<m>) = 1 - indicating that val<m> has been continuously asserted for longer than one data frame.
6. The clock will be stopped based on the r30[20:19] (clk_mode) configured before the start of the RX operation.
7. Clear r30[26, 25, 24] (rx_en<m>) to disable RX mode. All counters and flags will be reset.

30.4.1.3 Multiplier With Optional Accumulation (MPY/MAC)

Each PRU core has a designated unsigned multiplier with optional accumulation (MPY/MAC). The MAC has two modes of operation: Multiply Only or Multiply and Accumulate. The MAC is directly connected with the PRU internal registers R25–R29 and uses the broadside load/store PRU interface and XFR instructions to both control the mode of the MAC and import the multiplication results into the PRU.

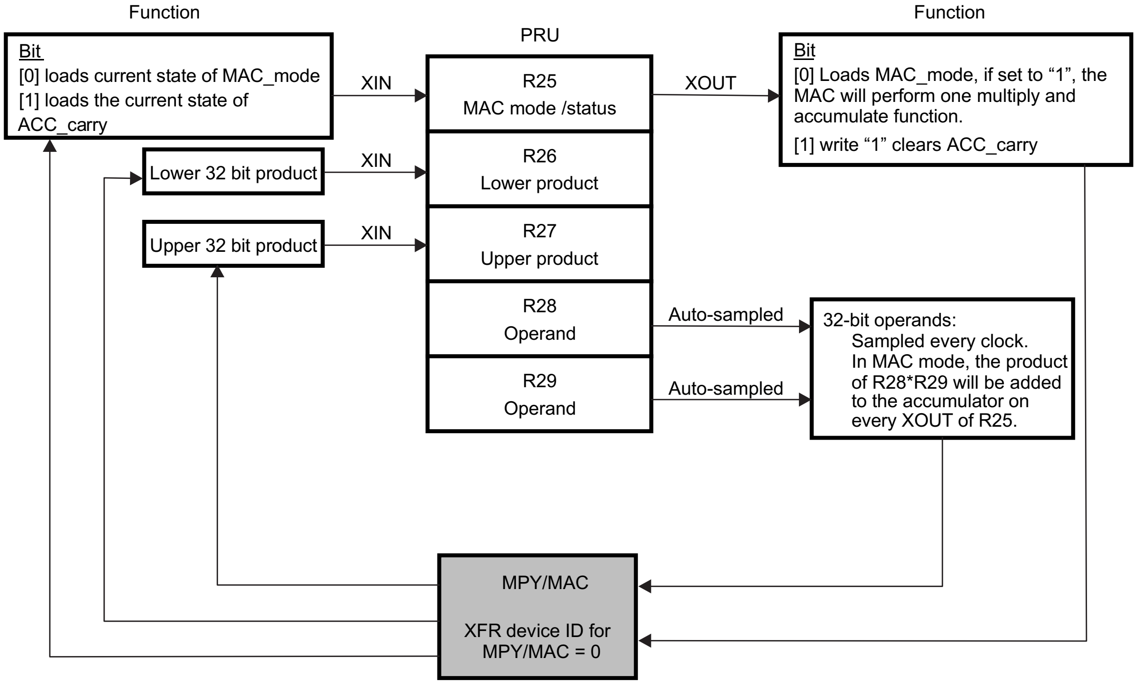
30.4.1.3.1 Features

- Configurable Multiply Only and Multiply and Accumulate functionality via PRU register R25
- 32-bit operands with direct connection to PRU registers R28 and R29
- 64-bit result (with carry flag) with direct connection to PRU registers R26 and R27
- PRU broadside interface and XFR instructions (XIN, XOUT) allow for importing multiplication results and initiating accumulate function

30.4.1.3.2 PRU and MPY/MAC Interface

The MAC directly connects with the PRU internal registers R25–R29 through use of the PRU broadside interface and XFR instructions. Figure 30-20 shows the functionality of each register.

Figure 30-20. Integration of the PRU and MPY/MAC



The XFR instructions (XIN and XOUT) are used to load/store register contents between the PRU core and the MAC. These instructions define the start, size, direction of the operation, and device ID. The device ID number corresponding to the MPY/MAC is shown in Table 30-25.

Table 30-25. MPY/MAC XFR ID

Device ID	Function
0	Selects MPY/MAC

The PRU register R25 is mapped to the MAC_CTRL_STATUS register (Table 30-26). The MAC's current status (MAC_mode and ACC_carry states) is loaded into R25 using the XIN command on R25. The PRU sets the MAC's mode and clears the ACC_carry using the XOUT command on R25.

Table 30-26. MAC_CTRL_STATUS Register (R25) Field Descriptions

Bit	Field	Value	Description
7-2	Reserved		Reserved
1	ACC_carry		Write 1 to clear
		0	64-bit accumulator carry has not occurred
		1	64-bit accumulator carry occurred
0	MAC_mode	0	Accumulation mode disabled and accumulator is cleared
		1	Accumulation mode enabled

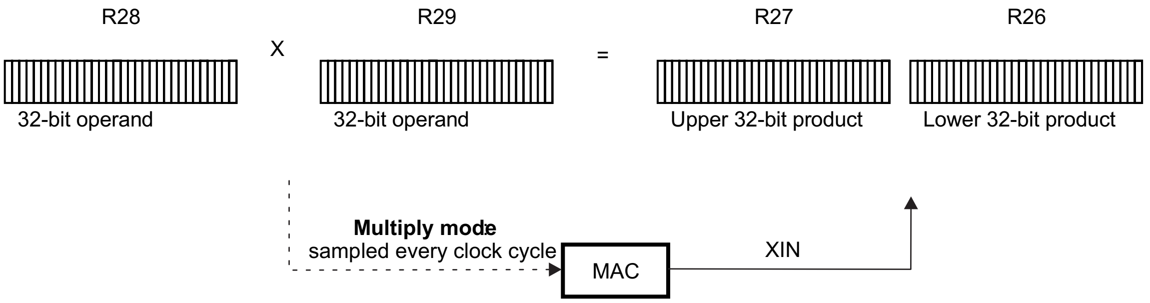
The two 32-bit operands for the multiplication are loaded into R28 and R29. These registers have a direction connection with the MAC, and the MAC samples these registers every clock cycle. Note, XOUT is not required to load the MAC. In multiply and accumulate mode, the product of R28*R29 will be added to the accumulator on every XOUT of R25.

The product from the MAC is linked to R26 (lower 32 bits) and R27 (upper 32 bits). The product is loaded into register R26 and R27 using XIN.

30.4.1.3.2.1 Multiply-Only Mode (Default State), MAC_mode = 0

On every clock cycle, the MAC multiplies the contents of R28 and R29.

Figure 30-21. Multiply-Only Mode Functional Diagram



The following steps are performed by the PRU firmware for multiply-only mode:

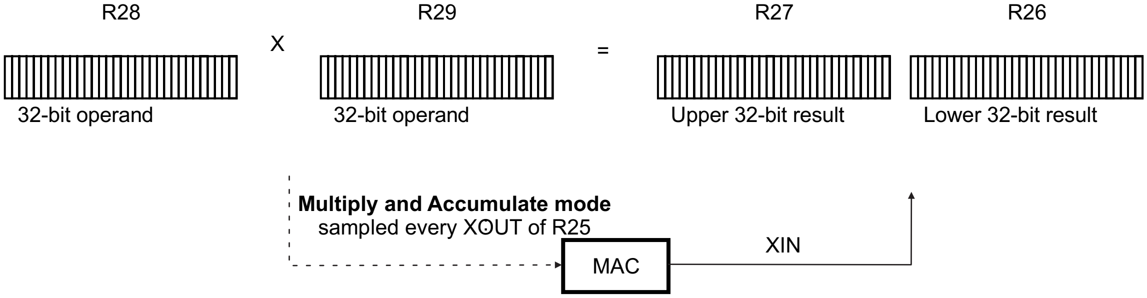
1. Enable multiply only MAC_mode.
   a. Clear R25[0] for multiply only mode.
   b. Store MAC_mode to MAC using XOUT instruction with the following parameters:
      - Device ID = 0
      - Base register = R25
      - Size = 1
2. Load operands into R28 and R29.
3. Delay at least 1 PRU cycle before executing XIN in step 4.
4. Load product into PRU using XIN instruction on R26, R27.

Repeat steps 2–4 for each new operand.

30.4.1.3.2.2 Multiply and Accumulate Mode, MAC_mode = 1

On every XOUT R25_reg[7:0] transaction, the MAC multiplies the contents of R28 and R29, adds the product to its accumulated result, and sets ACC_carry if an accumulation overflow occurs.

Figure 30-22. Multiply and Accumulate Mode Functional Diagram



The following steps are performed by the PRU firmware for multiply and accumulate mode:

1. Enable multiply and accumulate MAC_mode.
   a. Set R25[1:0] = 1 for accumulate mode.
   b. Store MAC_mode to MAC using XOUT instruction with the following parameters:
      - Device ID = 0
      - Base register = R25
      - Size = 1
2. Clear accumulator and carry flag.
   a. Set R25[1:0] = 3 to clear accumulator (R25[1]=1) and preserve accumulate mode (R25[0]=1).
   b. Store accumulator to MAC using XOUT instruction on R25.
3. Load operands into R28 and R29.
4. Multiply and accumulate, XOUT R25[1:0] = 1

   Repeat step 4 for each multiply and accumulate using same operands.

   Repeat step 3 and 4 for each multiply and accumulate for new operands.
5. Load the accumulated product into R26, R27, and the ACC_carry status into R25 using the XIN instruction.

Note: Steps one and two are required to set the accumulator mode and clear the accumulator and carry flag.

30.4.1.4 CRC16/32

The PRU0 and PRU1 cores of PRU-ICSS1/PRU-ICSS2 each have a designated CRC16/32 module.

In general, CRC adds error detection capability to communication systems. The CRC encoder appends redundant bits (or CRC bits) to the systematic data message. During reception of the data message, the received data is also encoded with the same CRC encoder. The 2 sets of CRC bits are compared together. If they atch, there were no transmission errors; and if they don’t match, a transmission error has been detected.

30.4.1.4.1 Features

CRC16/32 supports the following features:CRC16/32 supports the following features:

- Supports CRC32:
  – $x_{32} + x_{26} + x_{23} + x_{22} + x_{16} + x_{12} + x_{11} + x_{10} + x_8 + x_7 + x_5 + x_4 + x_2 + x + 1$
- Supports CRC16:
  – $x_{16} + x_{15} + x_2 + 1$
- PRU broadside interface and XFR instructions (XIN, XOUT) allow for importing CRC results and

executing accumulation function

30.4.1.4.2 PRU and CRC16/32 Interface

The CRC16/32 module directly connects with the PRU internal registers R25-R29 through use of the PRU broadside interface and XFR instructions. Table 30-27 shows the functionality of each register.

The XFR instructions (XIN and XOUT) are used to load/store register contents between the PRU core and the CRC16/32 module. These instructions define the start, size, direction of the operation, and device ID. The XFR device ID number corresponding to the CRC16/32 module is 1.

Table 30-27. CRC Register to PRU Port Mapping

CRC Register	R/W	Description	PRU Mapping
CRC_CFG	W	bit [0] CRC32_ENABLE: 0: CRC16 mode is selected. Hardware will auto-set init state of CRC_SEED to 0x0000_0000. Note CRC16 result value is only 16- bits 1: CRC32 mode is selected. Hardware will auto-set init state of CRC_SEED will be 0xffff_ffff. Always write all 4 bytes.	R25_reg
CRC_DATA_8_BFLIP	R	8-bit flip of CRC_DATA. CRC_DATA_8_BFLIP has the same byte order as CRC_DATA[31:0], but each byte has all bits flipped. CRC_DATA_32_FLIP[7:0] = CRC_DATA[0:7] CRC_DATA_32_FLIP[15:8] = CRC_DATA[8:15] CRC_DATA_32_FLIP[23:16] = CRC_DATA[16:23] CRC_DATA_32_FLIP[31:24] = CRC_DATA[24:31] For CRC16, only CRC_DATA_8_BFLIP[15:0] are valid. No auto reset on CRC_DATA_8_BFLIP read.	R27_reg
CRC_SEED	W	CRC SEED value. Hardware will auto-initialize the CRC_SEED value to 0x0000_0000 for CRC16 and 0xFFFF_FFFF for CRC32. Software only needs to initialize CRC_SEED if a different default value is required. Always write 4 bytes. Note when CRC_CFG[CRC32_ENABLE] is enabled, the hardware will switch the CRC_SEED value to 0xFFFF_FFFF. Reading the CRC_DATA register will reset the CRC value to the CRC_SEED state.	R28_reg
CRC_DATA_32_BFLIP	R	Full 32-bit flip of CRC_DATA CRC_DATA_32_BFLIP[0] = CRC_DATA[31] … CRC_DATA_32_BFLIP[31] = CRC_DATA[0] For CRC16, only CRC_DATA_32_BFLIP[31:16] are valid. No auto reset on CRC_DATA_32_BFLIP read.	R28_reg
CRC_DATA	RW	For Write, must use a fixed width throughout the session. The CRC module supports lower 8-bit, or lower 16-bit, or full 32-bit data widths. For Read, LSB or CRC_DATA[0] is first bit on the wire. Note for CRC16, only CRC_DATA[15:0] is valid. Hardware will delay CRC_DATA read operation up to 1 clock if it occurs back to back with a CRC_DATA write.	R29_reg

30.4.1.4.3 Programming Model

The following steps are performed by the PRU firmware to use the CRC module:

Step 1: Configuration (optional)

1. Configure CRC type: For CRC32 operation, set CRC32_ENABLE using XOUT instruction with the following parameters:
   - Device ID = 1
   - Base register = R25
   - Size = 1
2. Update CRC_SEED, if required using XOUT with the following parameters:
   - Device ID = 1

- Base Register = R28
- Size = 1 to 4

Step 2:

1. Load new CRC data into R29
2. Push CRC data to the CRC16/32 module using XOUT with the following parameters:
   - Device ID = 1
   - Base Register = R29
   - Size = 1 to 4
3. Load the accumulated CRC result into the PRU using the XIN instruction with the following parameters:
   - Device ID = 1
   - Base register = R29
   - Size = 4

Repeat Step 2, numbers 1 and 2 for each new CRC data.

NOTE: When a session starts, the PRU firmware must use the same write data width throughout the session.

30.4.1.5 PRU0/1 Scratch Pad

The PRU-ICSS supports a scratch pad with three independent banks accessible by the PRU cores. The PRU cores interact with the scratch pad through broadside load/store PRU interface and XFR instructions. The scratch pad can be used as a temporary place holder for the register contents of the PRU cores. Direct connection between the PRU cores is also supported for transferring register contents directly between the cores.

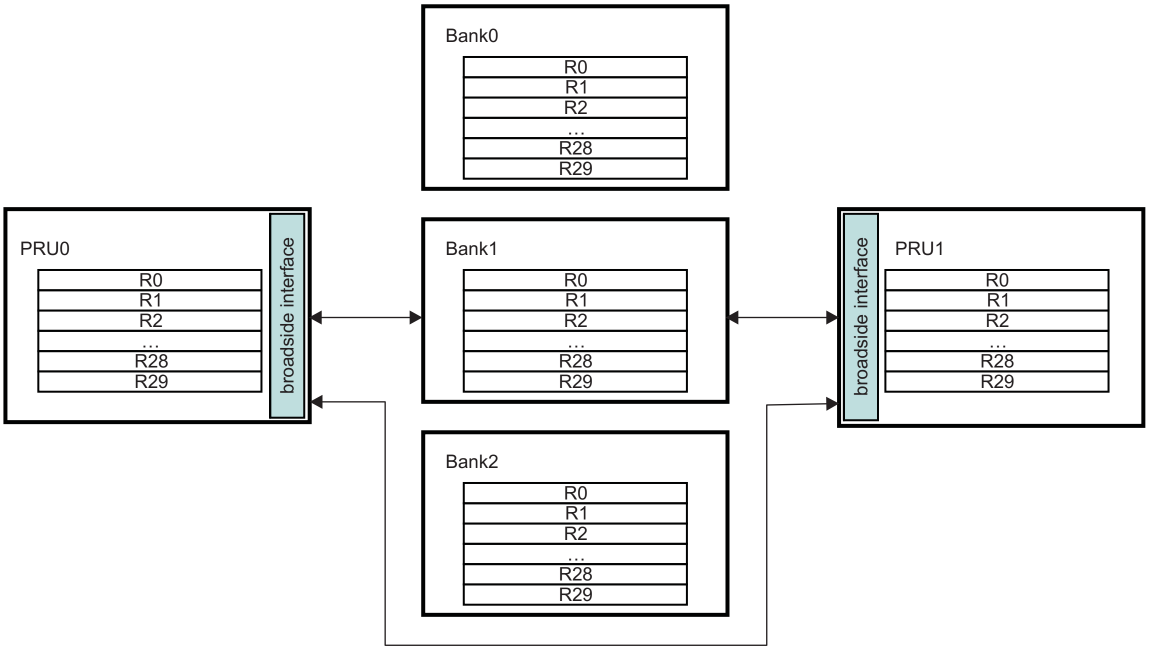
NOTE: Scratch pad may not be available for all subsystem instances. For a full list of available features for each subsystem instance, see Section 30.1.1, *Features*.

30.4.1.5.1 Features

The PRU-ICSS scratch pad supports the following features:

- Three scratch pad banks of 30, 32-bit registers (R29:0)
- Flexible load/store options
  - User-defined start byte and length of the transfer
  - Length of transfer ranges from one byte of a register to the entire register content (R29 to R0)
  - Simultaneous transactions supported between PRU0 ↔ Bank<n> and PRU1 ↔ Bank<m>
  - Direct connection of PRU0 → PRU1 or PRU1 → PRU0 for all registers R29–R0
- XFR instructions operate in one clock cycle
- Optional XIN/XOUT shift functionality allows remapping of registers (R<n> → R<m>) during load/store operation

Figure 30-23. Integration of PRU and Scratch Pad



30.4.1.5.2 Implementations and Operations

XFR instructions are used to load/store register contents between the PRU cores and the scratch pad banks. These instructions define the start, size, direction of the operation, and device ID. The device ID corresponds to the external source or destination (either a scratch pad bank or the other PRU core). The device ID numbers are shown in Table 30-28. Note the direct connect mode (device ID 14) can be used to synchronize the PRU cores. This mode requires the transmitting PRU core to execute XOUT and the receiving PRU core to execute XIN.

Table 30-28. Scratch Pad XFR ID

Device ID	Function
10	Selects Bank0
11	Selects Bank1
12	Selects Bank2
13	Reserved
14	Selects other PRU core (Direct connect mode)

A collision occurs when two XOUT commands simultaneously access the same asset or device ID. Table 30-29 shows the priority assigned to each operation when a collision occurs. In direct connect mode (device ID 14), any PRU transaction will be terminated if the stall is greater than 1024 cycles. This will generate the event pr<k>_xfr_timeout that is connected to INTC.

Table 30-29. Scratch Pad XFR Collision and Stall Conditions

Operation	Collision and Stall Handling
PRU<n> XOUT (→) bank[j]	If both PRU cores access the same bank simultaneously, PRU0 is given priority. PRU1 will temporarily stall until the PRU0 operation completes.
PRU<n> XOUT (→) PRU<m>	Direct connect mode requires the transmitting core (PRU<n>) to execute XOUT and the receiving core (PRU<m>) to execute XIN. If PRU<n> executes XOUT before PRU<m> executes XIN, then PRU<n> will stall until either PRU<m> executes XIN or the stall is greater than 1024 cycles.
PRU<m> XIN (←) PRU<n>	Direct connect mode requires the transmitting core (PRU<n>) to execute XOUT and the receiving core (PRU<m>) to execute XIN. If PRU<m> executes XIN before PRU<n> executes XOUT, then PRU<m> will stall until either PRU<n> executes XOUT or the stall is greater than 1024 cycles.

30.4.1.5.2.1 Optional XIN/XOUT Shift

The optional XIN/XOUT shift functionality allows register contents to be remapped or shifted within the destination's register space. For example, the contents of PRU0 R6-R8 could be remapped to Bank1 R10-12. The XIN/XOUT shift feature is not supported for direct connect mode, only for transfers between a PRU core and scratch pad bank.

The shift feature is enabled or disabled through the SPP register of the PRU-ICSS CFG register space. When enabled, R0[4:0] (internal to the PRU) defines the number of 32-bit registers in which content is shifted in the scratch pad bank. Note that scratch pad banks do not have registers R30 or R31.

30.4.1.5.2.2 Example Scratch Pad Operations

The following PRU firmware examples demonstrate the shift functionality. Note these assume the SHIFT_EN bit of the SPP register of the PRU-ICSS CFG register space has been set.

XOUT Shift By 4 Registers

Store R4:R7 to R8:R11 in bank0:

- Load 4 into R0.b0
- XOUT using the following parameters:
  - Device ID = 10
  - Base register = R4
  - Size = 16

XOUT Shift By 9 Registers, With Wrap Around

Store R25:R29 to R4:R8 in bank1:

- Load 9 into R0.b0
- XOUT using the following parameters:
  - Device ID = 11
  - Base register = R25
  - Size = 20

XIN Shift By 10 Registers

Load R14:R16 from bank2 to R4:R6

- Load 10 into R0.b0
- XIN using the following parameters:
  - Device ID = 12
  - Base register = R4
  - Size = 12

30.4.2 Interrupt Controller (INTC)

The PRU-ICSS interrupt controller (INTC) is an interface between interrupts coming from different parts of the system (referred to as system events; see Section 30.4.2.2) and the PRU-ICSS interrupt interface.

The PRU-ICSS INTC has the following features:

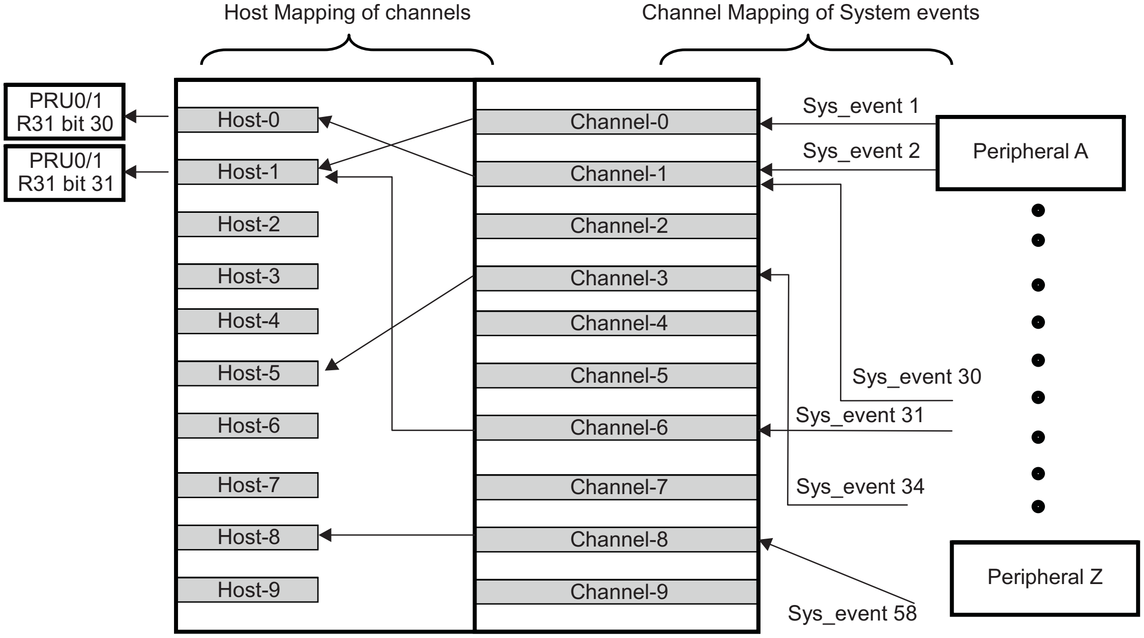
- Capturing up to 64 System Events
- Supports up to 10 interrupt channels.
- Generation of 10 Host Interrupts
  - 2 Host Interrupts for the PRUs.
  - 7 Host Interrupts exported from the PRU-ICSS for signaling the ARM interrupt controllers.
  - 1 Host Interrupt for the other PRU-ICSS.
- Each system event can be enabled and disabled.
- Each host event can be enabled and disabled.
- Hardware prioritization of events.

30.4.2.1 INTC Overview

The PRU-ICSS INTC supports up to 64 system events from different peripherals and PRUs to be mapped to 10 channels inside the INTC (see Figure 30-24). Interrupts from these 10 channels are further mapped to 10 Host Interrupts.

- Any of the 64 system events can be mapped to any of the 10 channels.
- Multiple interrupts can be mapped to a single channel.
- An interrupt should not be mapped to more than one channel.
- Any of the 10 channels can be mapped to any of the 10 host interrupts. It is recommended to map channel “x” to host interrupt “x”, where x is from 0 to 9
- A channel should not be mapped to more than one host interrupt
- For channels mapping to the same host interrupt, lower number channels have higher priority.
- For interrupts on same channel, priority is determined by the hardware interrupt number. The lower the interrupt number, the higher the priority.
- Host Interrupt 0 is connected to bit 30 in register 31 of PRU0 and PRU1.
- Host Interrupt 1 is connected to bit 31 in register 31 of PRU0 and PRU1.
- Host Interrupts 2-6 and 8-9 are exported from PRU-ICSS for signaling ARM interrupt controllers or other machines like EDMA.
- Host Interrupt 7 is exported from PRU-ICSS for signaling the other PRU-ICSS

Figure 30-24. Interrupt Controller Block Diagram



30.4.2.2 PRU-ICSS System Events

The PRU-ICSS system events are described as follows.

Table 30-30. PRU-ICSS0 System Events

Event Number	Signal Name (Standard Mode)	Source	Signal Name (MII_RT Mode)[1][2]
63	tpcc_int_pend_po1	EDMA3CC	
62	tpcc_errint_pend_po	EDMA3CC	
61	tptc_erint_pend_po	EDMA3TC0	
60	initiator_sinterrupt_q_n1	MAILBOX0- mail_u1_irq (mailbox interrupt for pru0)	
59	initiator_sinterrupt_q_n2	MAILBOX1 - mail_u2_irq (mailbox interrupt for pru1)	
58	Emulation Suspend Signal (software use)	DEBUGSS	
57	pwm_trip_zone	PWMSS3, PWMSS4, PWMSS5, EPWM	
56	pr1_host_intr5_intr_pend	PRU-ICSS1 Host Interrupt 7 (exported as pr1_host[5])	
55	mcasp_x_intr_pend	MCASP0, TX	(pr1_mii1_col and pr1_mii1_txen) (external)
54	mcasp_r_intr_pend	MCASP0, RX	PRU-ICSS0 PRU1_RX_EOF
53	gen_intr_pend	ADC0	PRU-ICSS0 MDIO_MII_LINK[1]
52	nirq	UART2	PRU-ICSS0 PORT1_TX_OVERFLOW

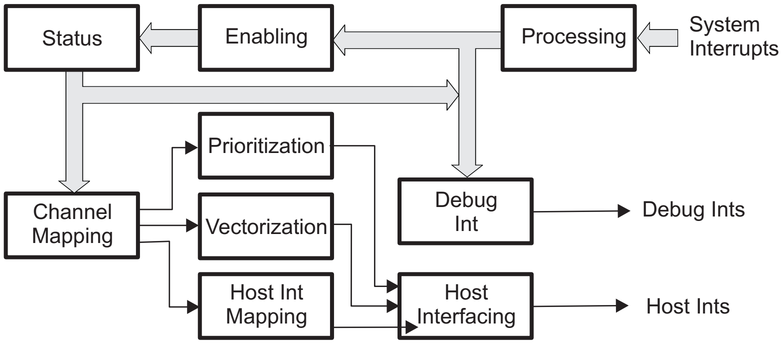
30.4.2.3 INTC Methodology

The INTC module controls the system event mapping to the host interrupt interface. System events are generated by the device peripherals or PRUs. The INTC receives the system events and maps them to internal channels. The channels are used to group interrupts together and to prioritize them. These channels are then mapped onto the host interrupts. Interrupts from the system side are active high in polarity. They are also pulse type of interrupts.

The INTC encompasses many functions to process the system events and prepare them for the host interface. These functions are: processing, enabling, status, channel mapping, host interrupt mapping, prioritization, and host interfacing. Figure 30-25 illustrates the flow of system events through the functions to the host. The following subsections describe each part of the flow.

Figure 30-25. Flow of System Events to Host



30.4.2.3.1 Interrupt Processing

This block does the following tasks:

- Synchronization of slower and asynchronous interrupts
- Conversion of polarity to active high
- Conversion of interrupt type to pulse interrupts

After the processing block, all interrupts will be active high pulses.

30.4.2.3.2 Interrupt Enabling

The next stage of INTC is to enable system events based on programmed settings. The following sequence is to be followed to enable interrupts:

- Enable required system events: System events that are required to get propagated to host are to be enabled individually by writing to IDX field in the system event enable indexed set register (EISR). The event to enable is the index value written. This sets the Enable Register bit of the given index.
- Enable required host interrupts: By writing to the IDX field in the host interrupt enable indexed set register (HIEISR), enable the required host interrupts. The host interrupt to enable is the index value written. This enables the host interrupt output or triggers the output again if that host interrupt is already enabled.
- Enable all host interrupts: By setting the EN bit in the global enable register (GER) to 1, all host interrupts will be enabled. Individual host interrupts are still enabled or disabled from their individual enables and are not overridden by the global enable.

30.4.2.3.3 Interrupt Status Checking

The next stage is to capture which system events are pending. There are two kinds of pending status: raw status and enabled status. Raw status is the pending status of the system event without regards to the enable bit for the system event. Enabled status is the pending status of the system events with the enable bits active. When the enable bit is inactive, the enabled status will always be inactive. The enabled status of system events is captured in system event status enabled/clear registers (SECR1-SECR2).

Status of system event 'N' is indicated by the Nth bit of SECR1-SECR2. Since there are 64 system events, two 32-bit registers are used to capture the enabled status of events. The pending status reflects whether the system event occurred since the last time the status register bit was cleared. Each bit in the status register can be individually cleared.

30.4.2.3.4 Interrupt Channel Mapping

The INTC has 10 internal channels to which enabled system events can be mapped. Channel 0 has highest priority and channel 9 has the lowest priority. Channels are used to group the system events into a smaller number of priorities that can be given to a host interface with a very small number of interrupt inputs.

When multiple system events are mapped to the same channel their interrupts are ORed together so that when one or more is active the output is active. The channel map registers (CMRm) define the channel for each system event. There is one register per 4 system events; therefore, there are 16 channel map registers for a system of 64 events. The channel for each system event can be set using these registers.

30.4.2.3.4.1 Host Interrupt Mapping

The hosts can be the PRUs or ARM CPU. The 10 channels from the INTC can mapped to any of the 10 Host interrupts. The Host map registers (HMR*m*) define the channel for each system event. There is one register per 4 channels; therefore, there are 3 host map registers for 10 channels. When multiple channels are mapped to the same host interrupt, then prioritization is done to select which event is in the highest-priority channel and which should be sent first to the host.

30.4.2.3.4.2 Interrupt Prioritization

The next stage of the INTC is prioritization. Since multiple events can feed into a single channel and multiple channels can feed into a single host interrupt, it is to read the status of all system events to determine the highest priority event that is pending. The INTC provides hardware to perform this prioritization with a given scheme so that software does not have to do this. There are two levels of prioritizations:

- The first level of prioritization is between the active channels for a host interrupt. Channel 0 has the highest priority and channel 9 has the lowest. So the first level of prioritization picks the lowest numbered active channel.
- The second level of prioritization is between the active system events for the prioritized channel. The system event in position 0 has the highest priority and system event 63 has the lowest priority. So the second level of prioritization picks the lowest position active system event.

This is the final prioritized system event for the host interrupt and is stored in the global prioritized index register (GPIR). The highest priority pending event with respect to each host interrupts can be obtained using the host interrupt prioritized index registers (HIPIRn).

30.4.2.3.5 Interrupt Nesting

The INTC can also perform a nesting function in its prioritization. Nesting is a method of enabling certain interrupts (usually higher-priority interrupts) when an interrupt is taken so that only those desired interrupts can trigger to the host while it is servicing the current interrupt. The typical usage is to nest on the current interrupt and disable all interrupts of the same or lower priority (or channel). Then the host will only be interrupted from a higher priority interrupt.

The nesting is done in one of three methods:

1. Nesting for all host interrupts, based on channel priority: When an interrupt is taken, the nesting level is set to its channel priority. From then, that channel priority and all lower priority channels will be disabled from generating host interrupts and only higher priority channels are allowed. When the interrupt is completely serviced, the nesting level is returned to its original value. When there is no interrupt being serviced, there are no channels disabled due to nesting. The global nesting level register (GNLR) allows the checking and setting of the global nesting level across all host interrupts. The nesting level is the channel (and all of lower priority channels) that are nested out because of a current interrupt.
2. Nesting for individual host interrupts, based on channel priority: Always nest based on channel priority

for each host interrupt individually. When an interrupt is taken on a host interrupt, then, the nesting level is set to its channel priority for just that host interrupt, and other host interrupts do not have their nesting affected. Then for that host interrupt, equal or lower priority channels will not interrupt the host but may on other host interrupts if programmed. When the interrupt is completely serviced the nesting level for the host interrupt is returned to its original value. The host interrupt nesting level registers (HINLR1 and HINLR2) display and control the nesting level for each host interrupt. The nesting level controls which channel and lower priority channels are nested. There is one register per host interrupt.

3. Software manually performs the nesting of interrupts. When an interrupt is taken, the software will disable all the host interrupts, manually update the enables for any or all the system events, and then re-enable all the host interrupts. This now allows only the system events that are still enabled to trigger to the host. When the interrupt is completely serviced the software must reverse the changes to re-enable the nested out system events. This method requires the most software interaction but gives the most flexibility if simple channel-based nesting mechanisms are not adequate.

30.4.2.3.6 Interrupt Status Clearing

After servicing the event (after execution of the ISR), event status is to be cleared. If a system event status is not cleared, then another host interrupt may not be triggered or another host interrupt may be triggered incorrectly. It is also essential to clear all system events before the PRU is halted as the PRU does not power down unless all the event status bits are cleared. For clearing the status of an event, whose event number is N, write a 1 to the Nth bit position in the system event status enabled/clear registers (SECR1-SECR2). System event N can also be cleared by writing the value N into the system event status indexed clear register (SICR).

30.4.2.4 Interrupt Disabling

At any time, if any event is not to be propagated to the host, then that event should be disabled. For disabling an event whose event number is N, write a 1 to the Nth bit in the system event enable clear registers (ECR1-ECR2). system event N can also be disabled by writing the value N in the system event enable indexed clear register (EICR).

30.4.2.5 INTC Basic Programming Model

Follow these steps to configure the interrupt controller.

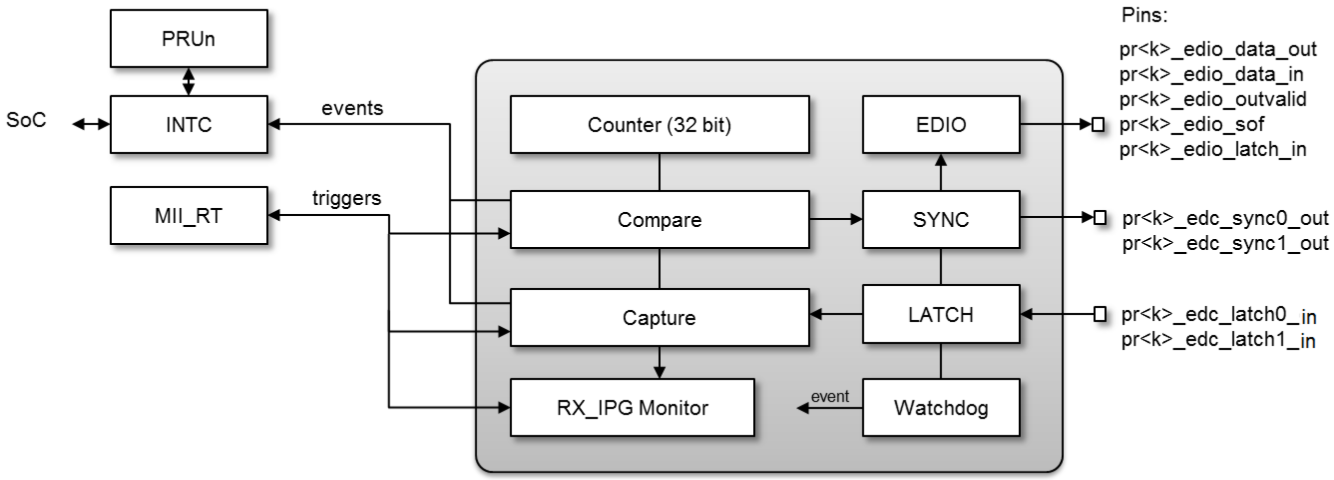
1. Set polarity and type of system event through the System Event Polarity Registers (SIPR1 and SPIR2) and the System Event Type Registers (SITR1 and SITR2). Polarity of all system events is always high. Type of all system events is always pulse.
2. Map system event to INTC channel through CHANMAP registers.
3. Map channel to host interrupt through HOSTMAP registers. Recommend channel “x” be mapped to host interrupt “x”.
4. Clear system event by writing 1s to SECR registers.
5. Enable host interrupt by writing index value to HIER register.
6. Enable interrupt nesting if desired.
7. Globally enable all interrupts through GER register.

30.4.3 Industrial Ethernet Peripheral (IEP)

The industrial ethernet peripheral (IEP) performs hardware work required for industrial ethernet functions. The IEP module features an industrial ethernet timer with 16 compare events, industrial ethernet sync generator and latch capture, industrial ethernet watchdog timer, and a digital I/O port (DIGIO). The IEP functional block diagram is shown in Figure 30-26.

The industrial ethernet peripheral (IEP) is intended to do the hardware work required for industrial ethernet functions of the timer/system timer, sync 0/1 generation, latch0/1 capture, watchdog timer (WD), and Digital I/O port (DIGIO). The IEP functional block diagram is shown in Figure 30-26. The following chapter will introduce these in register view.

Figure 30-26. Industrial Ethernet Peripheral Block Diagram



(1) Internal signal wire

(2) External pin input/output

A For SYNC0 trigger of start time.

B For SYNC1 trigger only in independent mode.

30.4.3.1 IEP Clock Source

The IEP has a selectable module input clock. The clock source is selected by the state of the IEPCLK.OCP_EN bit within the PRU-ICSS CFG register space. Two clock sources are supported for the IEP input clock:

- iep_clk (default): Runs at 200 MHz
- ocp_clk

Switching from iep_clk to ocp_clk is done by writing 1 to the IEPCLK.OCP_EN bit. This is a one time configuration step before enabling the IEP function. Switching back from ocp_clk to iep_clk is only supported through a hardware reset of the PRU-ICSS.

30.4.3.2 Industrial Ethernet Timer

The industrial ethernet timer is a simple 32-bit timer. This timer is intended for use by industrial ethernet functions but can also be leveraged as a generic timer in other applications.

30.4.3.2.1 Features

The industrial ethernet timer supports the following features:

- One master 32-bit count-up counter with an overflow status bit.
  - Runs on iep_clk or ocp_clk
  - Write 1 to clear status.

  - Supports a programmable increment value from 1 to 16 (default 5).
  - An optional compensation method allows the increment value to apply a compensation increment value from 1 to 16, counting up to 2^24 iep_clk/ocp_clk events.
- Sixteen 32-bit compare registers (CMP[15:0], CMP_STAT).
  - Sixteen status bits, write 1 to clear.
  - Sixteen individual event outputs.
  - One global event (any compare event) output for interrupt generation triggered by any compare event.
- Ten 32-bit capture registers (CAPR[5:0], CAPR[7:6], CAPF[7:6]).
  - Eight capture inputs with optional synchronous or asynchronous mode.
    - Six rise-only capture inputs (CAPR[5:0]).
    - Two rise-and-fall capture inputs:
      - CAPR[7] and CAPF[7]
      - CAPR[6] and CAPF[6]
    - One input signal will be used by two capture registers:
      - One register for rising edge.
      - One register for falling edge.
    - One global event (any capture event) output for interrupt generation triggered by any capture event.
- 32 outputs, one high level and one high pulse for each compare hit event.
- CMP[0], if enabled, will reset the counter on the next iep_clk/ocp_clk cycle.

30.4.3.2.2 Basic Programming Model

Follow these basic steps to configure the IEP Timer.

1. Initialize timer to known state (default values).
   a. Disable counter (GLB_CFG.CNT_ENABLE).
   b. Reset Count Register (CNT) by writing 0xFFFFFFFF to clear.
   c. Clear overflow status register (GLB_STS.CNT_OVF).
   d. Clear compare status (STS).
2. Set compare values (CMP0-CMPx).
3. Enable compare events (CMP_CFG.CMP_EN).
4. Set increment value (GLB_CFG.DEFAULT_INC).
5. Set compensation value (COMPEN.COMPEN_CNT).
6. Enable counter (GLB_CFG.CNT_ENABLE).

30.4.3.2.3 Industrial Ethernet Mapping

Some of the capture inputs and compare registers are mapped to specific industrial Ethernet functions in hardware, shown in Table 30-32. All capture inputs are mapped to industrial ethernet functions, and these inputs are not available for any other application. The cmp1 and cmp2 compare registers also function as the start time triggers for SYNC0 and SYNC1, respectively.

Table 30-32. Industrial Ethernet Timer Mode Mapping

Capture Input	IEP Line/Function
cap0, rise only	PRU0_RX_SOF
cap1, rise only	PRU0_RX_SFD
cap2, rise only	PRU1_RX_SOF
cap3, rise only	PRU1_RX_SFD
cap4, rise only	PORT0_TX_SOF
cap5, rise only	PORT1_TX_SOF
cap6, rise and fall	latch0_in, SOC IO inputs
cap7, rise and fall	latch1_in, SOC IO inputs
cmp1	For SYNC0 trigger of start time
cmp2	For SYNC1 trigger of start time only valid in the independent mode
cmp3	For MII TX0 start trigger, if MII register TXCFG0/1[TX_EN_MODE] is enabled.
cmp4	For MII TX1 start trigger, if MII register TXCFG0/1[TX_EN_MODE] is enabled.

30.4.3.3 Industrial Ethernet SYNC0/SYNC1

The industrial ethernet sync block supports the generation of two synchronization signals: SYNC0 and SYNC1. SYNC0 and SYNC1 can be directly mapped to output signals (pr1_edc_sycn0_out and pr1_edc_sync1_out) for external devices to use. They can also be used for internal synchronization within the PRU-ICSS. These signals are also mapped as system events and can therefore be mapped to the ARM core's Host interrupts.

30.4.3.3.1 Features

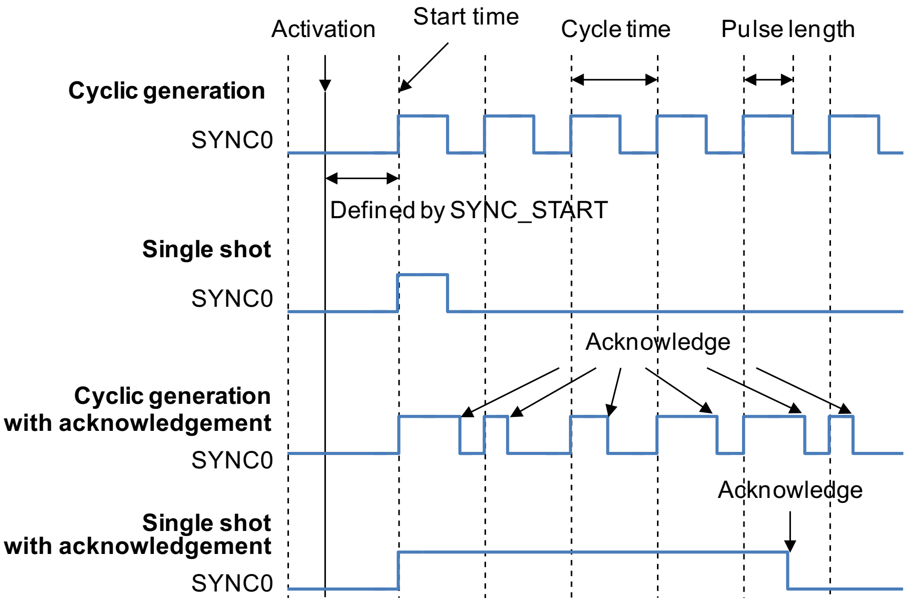
The industrial ethernet sync block supports the following features:

- Two synchronize generation signals (SYNC0, SYNC1)
  - Activation time synchronized with IEP Timer
    - CMP[1] triggers SYNC0 activation time
    - CMP[2] triggers SYNC1 activation time (only valid in the independent mode)
  - Pulse width defined by registers or ack mode (remain asserted until software acknowledged)
  - Cyclic or single-shot operation
  - Option to enable or disable sync generation
- Programmable number of clock cycles between the start of SYNC0 to the start of SYNC1

30.4.3.3.2 Sync Generation Modes

There are four modes of operation for the sync signals: cyclic mode, single shot mode, cyclic with acknowledge mode, and single shot with acknowledge mode. Figure 30-27 shows examples of these modes. The start time is set by the SYNC_START register. The cycle time is configured by the SYNC0_PERIOD register. The pulse length is defined by SYNC_PWIDTH register.

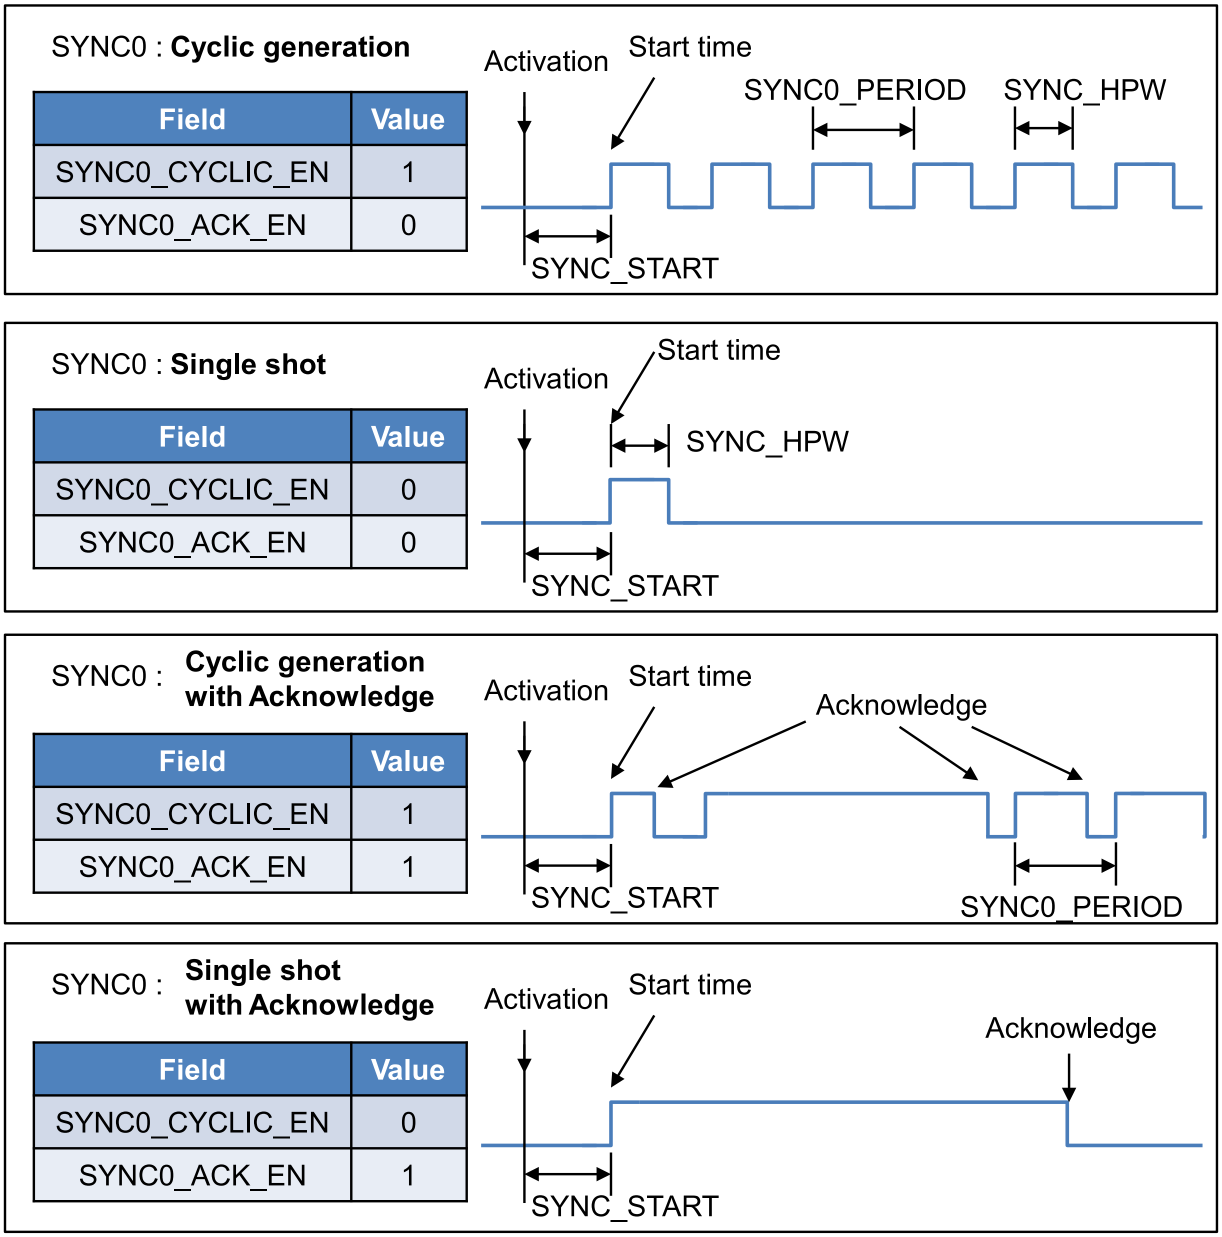
Figure 30-27. Sync Signal Generation Mode



In SYNC1 dependent mode (SYNC_CTRL.sync1_ind_en = 0), SYNC1 depends on SYNC0 and the start time of the SYNC1 can be defined by the SYNC1_DELAY register. Figure 30-28 shows different examples when changing the value in the SYNC1_DELAY register. Note if the SYNC1 delay time is 0, SYNC1 reflects SYNC0.

Cyclic generation cannot be used for network time synchronized applications because only the CMP1/CMP2 hit occurs in the compensated time domain.

Figure 30-28. Examples of the Dependent Mode of SYNC1



SYNC0 : **Cyclic generation**

Field	Value
SYNC0_CYCLIC_EN	1
SYNC0_ACK_EN	0

SYNC0 : **Single shot**

Field	Value
SYNC0_CYCLIC_EN	0
SYNC0_ACK_EN	0

SYNC0 : **Cyclic generation with Acknowledge**

Field	Value
SYNC0_CYCLIC_EN	1
SYNC0_ACK_EN	1

SYNC0 : **Single shot with Acknowledge**

Field	Value
SYNC0_CYCLIC_EN	0
SYNC0_ACK_EN	1

30.4.3.4 Industrial Ethernet Watchdog Timer

In industrial ethernet applications, the watchdog timer (WD) is used as a safety feature to monitor process data communication and to turn off the outputs of the digital input/output (DIGIO) functional block after a set time. The WD will thereby protect the system from errors or faults by timeout or expiration. The expiration is used to initiate corrective action in order to keep the system in a safe state and restore normal operation based on configuration. Therefore, if the system is stable, the watchdog timer should be regularly reset or cleared to avoid timeout or expiration.

30.4.3.4.1 Features

The industrial ethernet watchdog timer supports the following features:

- One 32-bit pre-divider for generating a WD clock (default 100μs) based on iep_clk input
- Two 16-bit Watchdog Timers:
  - PDI_WD for Sync Managers WD, used in conjunction with digital input/output (DIGIO)
  - PD_WD for data link layer user WD, used in conjunction with data link layer or application layer interface actions

30.4.3.5 Industrial Ethernet Digital I/O (DIGIO)

The IEP digital I/O (DIGIO) block provides dedicated I/Os intended for industrial ethernet protocols, but they can also be used as generic I/Os in other applications.

The IEP digital I/O (DIGIO) block provides dedicated I/Os for industrial ethernet protocols. The digital inputs can be sampled when specific events occur or continuously as a raw input. Likewise, driving the digital outputs can be triggered by specific events or controlled by software. The timing, delay cycle clocks, data sources, and data valid of the digital input and outputs are controlled by the DIGIO_CTRL and DIGIO_EXP registers.

Additionally, the IEP DIGIO block can be used as generic I/Os in other applications.

30.4.3.5.1 Features

The industrial ethernet digital I/O supports the following features:

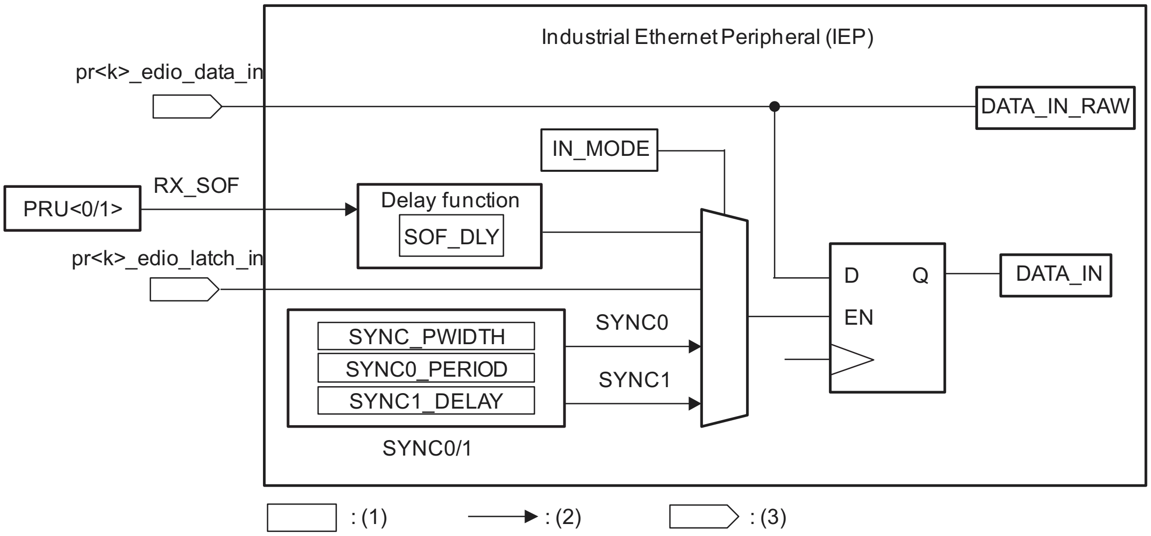
- Digital data output
  - 32 channels (pr<k>_edio_data_out[31:0])
  - Software controls enable signal driving output data output
  - Five event options for driving output data output
    - End of frame event (PRU0/1_RX_EOF)
    - SYNC0 events
    - SYNC1 events
    - Watchdog trigger
    - Software enable
- Digital data out enable (optional tri-state control)
- Digital data input
  - 32 channels (pr<k>_edio_data_in[31:0])
  - DIGIO_DATA_IN_RAW supports direct sampling of pr<k>_edio_data_in
  - External latch event signal (pr<k>_edio_latch_in) triggers a pulse on which pr<k>_edio_data_in is sampled
  - DIGIO_DATA_IN supports four event options to trigger sampling of pr<k>_edio_data_in
    - Start of frame event in start of frame (SOF) mode
    - pr<k>_edio_latch_in_event
    - SYNC0 events
    - SYNC1 events

NOTE: Some devices may not pin out all 32 data signals. See Table 30-3, *PRU-ICSS Pin List*, for the data pins that are available on this device.

30.4.3.5.2 DIGIO Block Diagrams

Figure 30-29 shows the signals and registers for capturing the DIGIO data in. Note that IN_MODE in the DIGIO_CTRL register must be set to 1 for data to be latched on the external pr<k>_edio_latch_in signal.Note in PRU0/1_RX_SOF mode, the delay time of capturing pr1_edio_data_in is programmable through the SOF_DLY bit of the DIGIO_EXT register.

Figure 30-29. IEP DIGIO Data In



(1) Register

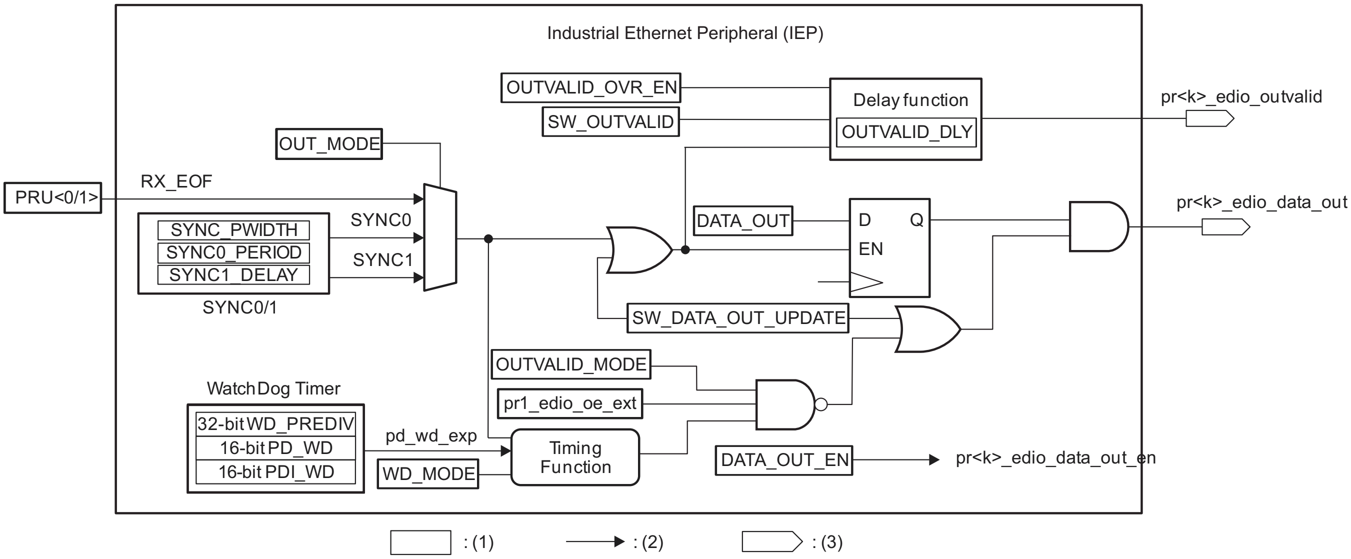
(2) Internal signal wire

(3) External pin input/output

Figure 30-30 shows the signals and registers for driving the DIGIO data out.

Figure 30-30 shows the signals and registers for driving the industrial ethernet data out. The pr1_edio_data_out is immediately forced to zero when OUTVALID_MODE = 1, pr1_edio_oe_ext = 1, and PD_WD_EXP = 1, or the next update hardware post PD_WD_EXP. Delay assertion of pr1_edio_outvalid from pr1_edio_data_out update events are controlled by software (SW_OUTVALID).

Figure 30-30. IEP DIGIO Data Out



(1) Register

(2) Internal signal wire

(3) External pin input/output

30.4.3.5.3 Basic Programming Model

Follow these steps to configure and read the DIGIO Data Input.

1. Read DIGIO_DATA_IN_RAW for raw input data.

   or

1. Enable sampling of pr<k>_edio_data_in[31:0] by setting DIGIO_CTRL.IN_MODE.
2. Read DIGIO_DATA_IN for data sampled by the selected trigger source.

Follow these steps to configure and write to the DIGIO Data Output:

1. Pre-configure DIGIO by setting DIGIO_EXP.OUTVALID_OVR_EN and DIGIO_EXP.SW_DATA_OUT_UPDATE.
2. Write to DIGIO_DATA_OUT to configure output data.
3. To Hi-Z output, set DIGIO_DATA_OUT_EN. (Clear DIGIO_DATA_OUT_EN to drive value stored in DIGIO_DATA_OUT.)

30.4.4 Universal Asynchronous Receiver/Transmitter

30.4.4.1 Introduction

30.4.4.1.1 Purpose of the Peripheral

The PRU UART peripheral within the PRU-ICSS is based on the industry standard TL16C550 asynchronous communications element, which in turn is a functional upgrade of the TL16C450. Functionally similar to the TL16C450 on power up (single character or TL16C450 mode), the UART can be placed in an alternate FIFO (TL16C550) mode. This relieves the CPU of excessive software overhead by buffering received and transmitted characters. The receiver and transmitter FIFOs store up to 16 bytes including three additional bits of error status per byte for the receiver FIFO.

The UART performs serial-to-parallel conversions on data received from a peripheral device and parallel-to-serial conversion on data received from the CPU. The CPU can read the UART status at any time. The UART includes control capability and a processor interrupt system that can be tailored to minimize software management of the communications link.

The UART includes a programmable baud rate generator capable of dividing the PRU_ICSS_UART_CLK input clock by divisors from 1 to 65535 and producing a 16× reference clock or a 13× reference clock for the internal transmitter and receiver logic. For detailed timing and electrical specifications for the UART, see your device-specific data manual.

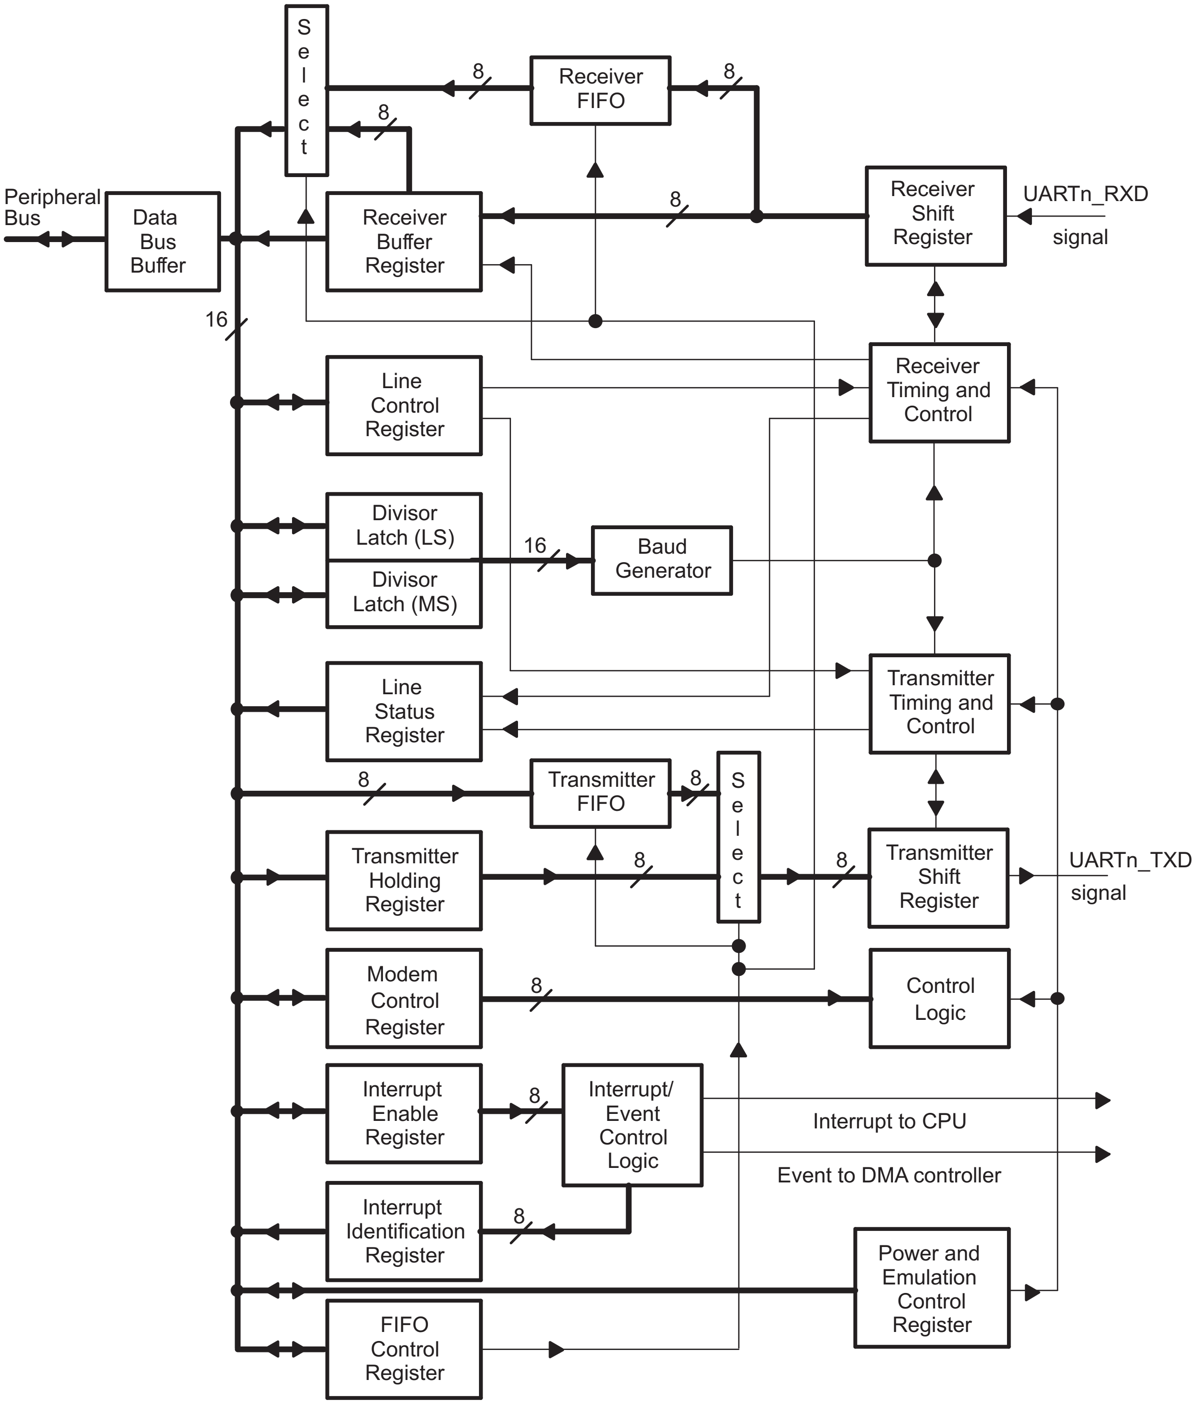
30.4.4.1.2 Functional Block Diagram

A functional block diagram of the UART is shown in Figure 30-31.

30.4.4.1.3 Industry Standard(s) Compliance Statement

The UART peripheral is based on the industry standard TL16C550 asynchronous communications element, which is a functional upgrade of the TL16C450. The information in this chapter assumes you are familiar with these standards.

Figure 30-31. UART Block Diagram



NOTE: The value *n* indicates the applicable UART where there are multiple instances. For the PRU-ICSS, there is only one instance and all UART signals should reflect this (e.g., UART0_TXD instead of UARTn_TXD).

30.4.4.2 Functional Description

30.4.4.2.1 Clock Generation and Control

The UART bit clock is derived from an input clock to the UART. See your device-specific data manual to check the maximum data rate supported by the UART.

Figure 30-32 is a conceptual clock generation diagram for the UART. The PRU_ICSS_UART_CLK is input to the Clock Generator, which uses a programmable divider to produce the UART input clock. The UART contains a programmable baud generator that takes the UART input clock and divides it by a divisor in the range between 1 and (2^{16} - 1) to produce a baud clock (BCLK). The frequency of BCLK is sixteen times (16×) the baud rate (each received or transmitted bit lasts 16 BCLK cycles) or thirteen times (13×) the baud rate (each received or transmitted bit lasts 13 BCLK cycles). When the UART is receiving, the bit is sampled in the 8th BCLK cycle for 16× over sampling mode and on the 6th BCLK cycle for 13× over-sampling mode. The 16× or 13× reference clock is selected by configuring the OSM_SEL bit in the mode definition register (MDR). The formula to calculate the divisor is:

$$\textbf{Divisor} = \frac{\textbf{UART input clock frequency}}{\textbf{Desired baud rate} \times \textbf{16}} \qquad [\textbf{MDR.OSM\_SEL} = \textbf{0}]$$

$$\textbf{Divisor} = \frac{\textbf{UART input clock frequency}}{\textbf{Desired baud rate} \times \textbf{13}} \qquad [\textbf{MDR.OSM\_SEL} = \textbf{1}]$$

Two 8-bit register fields (DLH and DLL), called divisor latches, hold this 16-bit divisor. DLH holds the most significant bits of the divisor, and DLL holds the least significant bits of the divisor. For information about these register fields, see the UART register descriptions. These divisor latches must be loaded during initialization of the UART in order to ensure desired operation of the baud generator. Writing to the divisor latches results in two wait states being inserted during the write access while the baud generator is loaded with the new value.

Figure 30-33 summarizes the relationship between the transferred data bit, BCLK, and the UART input clock. Note that the timing relationship depicted in Figure 30-33 shows that each bit lasts for 16 BCLK cycles . This is in case of 16x over-sampling mode. For 13× over-sampling mode each bit lasts for 13 BCLK cycles .

Example baud rates and divisor values relative to a 192-MHz UART input clock and 16× over-sampling mode are shown in Table 30-33.

Figure 30-32. UART Clock Generation Diagram

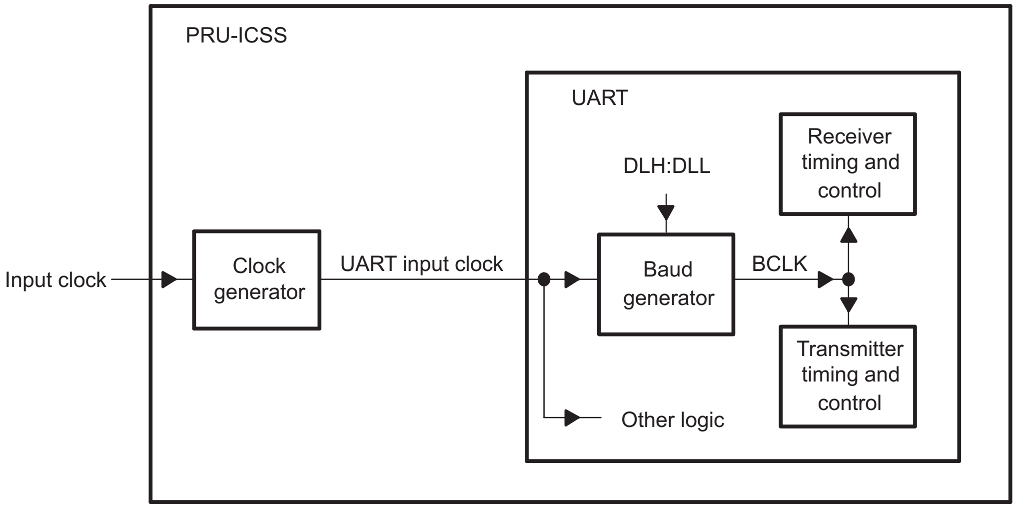


Figure 30-33. Relationships Between Data Bit, BCLK, and UART Input Clock

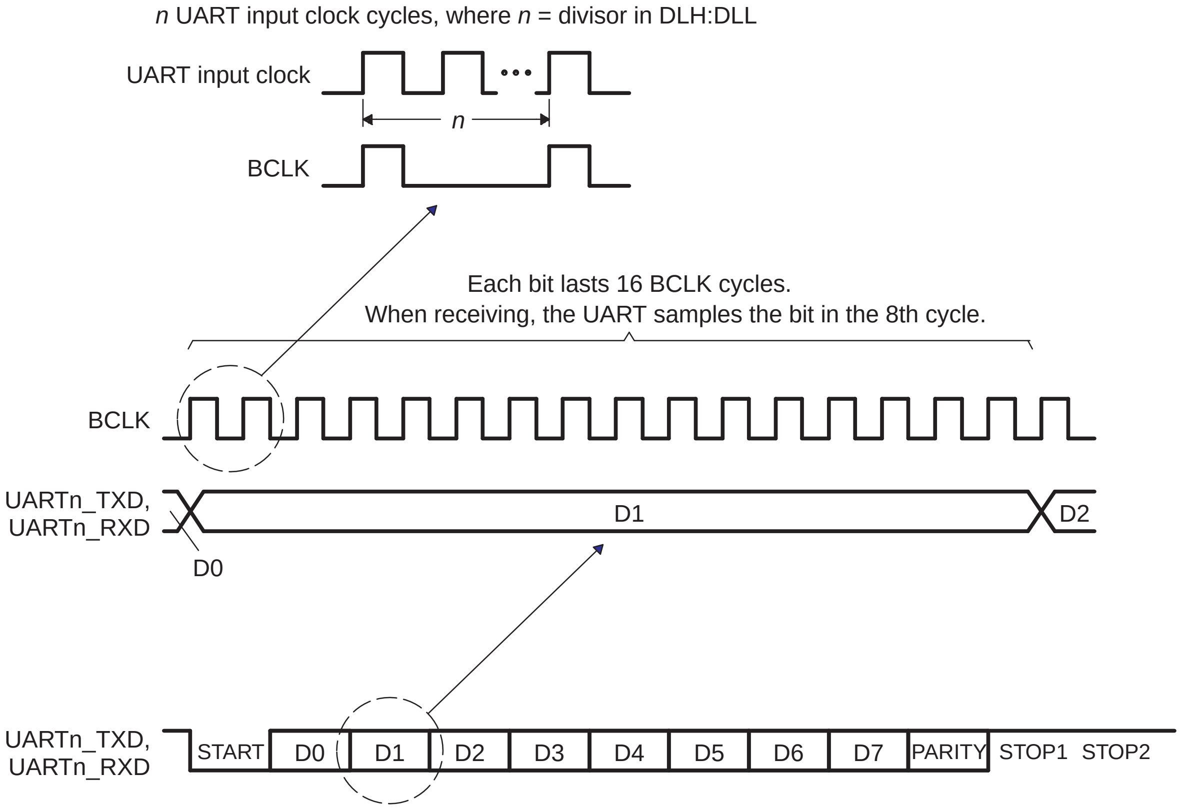

Table 30-33. Baud Rate Examples for 192-MHZ UART Input Clock and 16× Over-sampling Mode

Baud Rate	Divisor Value	Actual Baud Rate	Error (%)
2400	5000	2400	0.00
4800	2500	4800	0.00
9600	1250	9600	0.00
19200	625	19200	0.00
38400	313	38338.658	–0.16
56000	214	56074.766	0.13
128000	94	127659.574	–0.27
300000	40	300000	0.00

Table 30-34. Baud Rate Examples for 192-MHZ UART Input Clock and 13× Over-sampling Mode

Baud Rate	Divisor Value	Actual Baud Rate	Error (%)
2400	6154	2399.940	–0.0025
4800	3077	4799.880	–0.0025
9600	1538	9602.881	0.03
19200	769	19205.762	0.03
38400	385	38361.638	–0.10
56000	264	55944.056	–0.10
128000	115	128428.094	0.33
300000	49	301412.873	0.47

30.4.4.2.2 Signal Descriptions

The UARTs utilize a minimal number of signal connections to interface with external devices. The UART signal descriptions are included in Table 30-35. Note that the number of UARTs and their supported features vary on each device. See your device-specific data manual for more details.

Table 30-35. UART Signal Descriptions

Signal Name[1]	Signal Type	Function
UARTn_TXD	Output	Serial data transmit
UARTn_RXD	Input	Serial data receive
$\overline{\text{UARTn\_CTS}}$ [2]	Input	Clear-to-Send handshaking signal
$\overline{\text{UARTn\_RTS}}$ [2]	Output	Request-to-Send handshaking signal

[1] The value *n* indicates the applicable UART; that is, UART0, UART1, etc.

[2] This signal is not supported in all UARTs. See your device-specific data manual to check if it is supported.

30.4.4.2.3 Pin Multiplexing

Extensive pin multiplexing is used to accommodate the largest number of peripheral functions in the smallest possible package. Pin multiplexing is controlled using a combination of hardware configuration at device reset and software programmable register settings. See your device-specific data manual to determine how pin multiplexing affects the UART.

30.4.4.2.4 Protocol Description

30.4.4.2.4.1 Transmission

The UART transmitter section includes a transmitter hold register (THR) and a transmitter shift register (TSR). When the UART is in the FIFO mode, THR is a 16-byte FIFO. Transmitter section control is a function of the UART line control register (LCR). Based on the settings chosen in LCR, the UART transmitter sends the following to the receiving device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1, 1.5, or 2 STOP bits

30.4.4.2.4.2 Reception

The UART receiver section includes a receiver shift register (RSR) and a receiver buffer register (RBR). When the UART is in the FIFO mode, RBR is a 16-byte FIFO. Receiver section control is a function of the UART line control register (LCR). Based on the settings chosen in LCR, the UART receiver accepts the following from the transmitting device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1 STOP bit (any other STOP bits transferred with the above data are not detected)

30.4.4.2.4.3 Data Format

The UART transmits in the following format:

1 START bit + data bits (5, 6, 7, 8) + 1 PARITY bit (optional) + STOP bit (1, 1.5, 2)

It transmits 1 START bit; 5, 6, 7, or 8 data bits, depending on the data width selection; 1 PARITY bit, if parity is selected; and 1, 1.5, or 2 STOP bits, depending on the STOP bit selection.

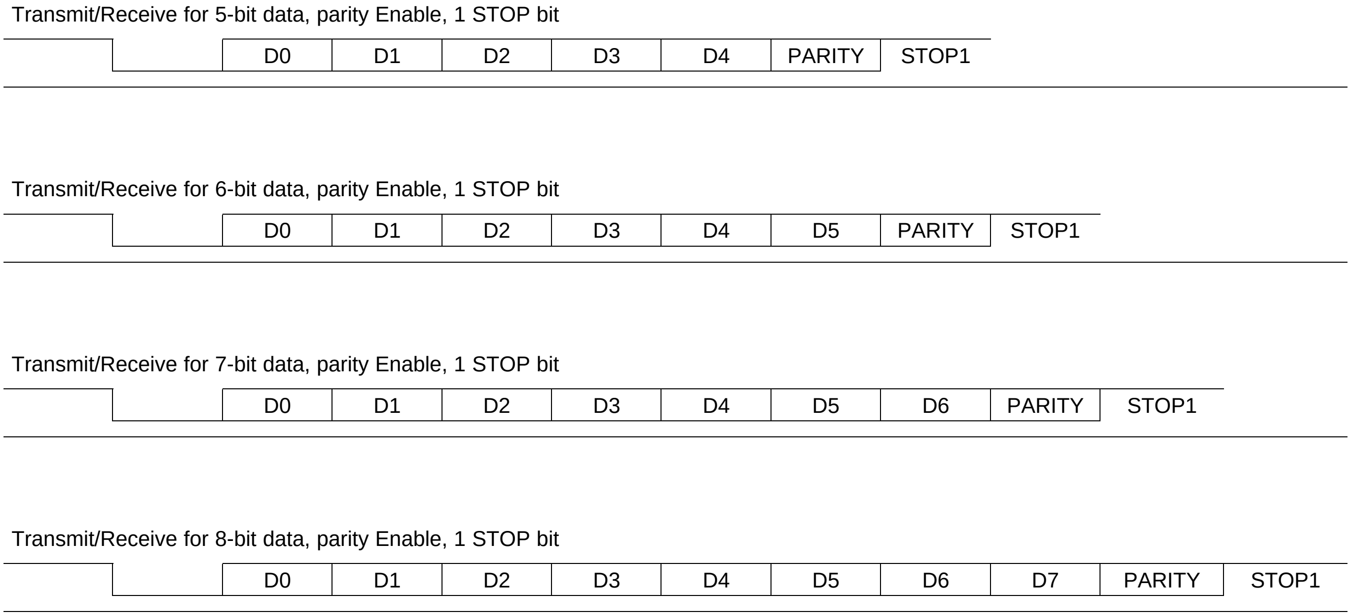
The UART receives in the following format:

1 START bit + data bits (5, 6, 7, 8) + 1 PARITY bit (optional) + 1 STOP bit

It receives 1 START bit; 5, 6, 7, or 8 data bits, depending on the data width selection; 1 PARITY bit, if parity is selected; and 1 STOP bit.

The protocol formats are shown in Figure 30-34.

Figure 30-34. UART Protocol Formats



30.4.4.2.5 Operation

30.4.4.2.5.1 Transmission

The UART transmitter section includes a transmitter hold register (THR) and a transmitter shift register (TSR). When the UART is in the FIFO mode, THR is a 16-byte FIFO. Transmitter section control is a function of the UART line control register (LCR). Based on the settings chosen in LCR, the UART transmitter sends the following to the receiving device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1, 1.5, or 2 STOP bits

THR receives data from the internal data bus, and when TSR is ready, the UART moves the data from THR to TSR. The UART serializes the data in TSR and transmits the data on the UARTn_TXD pin.

In the non-FIFO mode, if THR is empty and the THR empty (THRE) interrupt is enabled in the interrupt enable register (IER), an interrupt is generated. This interrupt is cleared when a character is loaded into THR or the interrupt identification register (IIR) is read. In the FIFO mode, the interrupt is generated when the transmitter FIFO is empty, and it is cleared when at least one byte is loaded into the FIFO or IIR is read.

30.4.4.2.5.2 Reception

The UART receiver section includes a receiver shift register (RSR) and a receiver buffer register (RBR). When the UART is in the FIFO mode, RBR is a 16-byte FIFO. Timing is supplied by the 16× receiver clock. Receiver section control is a function of the UART line control register (LCR). Based on the settings chosen in LCR, the UART receiver accepts the following from the transmitting device:

- 1 START bit
- 5, 6, 7, or 8 data bits
- 1 PARITY bit (optional)
- 1 STOP bit (any other STOP bits transferred with the above data are not detected)

RSR receives the data bits from the UARTn_RXD pin. Then RSR concatenates the data bits and moves the resulting value into RBR (or the receiver FIFO). The UART also stores three bits of error status information next to each received character, to record a parity error, framing error, or break.

In the non-FIFO mode, when a character is placed in RBR and the receiver data-ready interrupt is enabled in the interrupt enable register (IER), an interrupt is generated. This interrupt is cleared when the character is read from RBR. In the FIFO mode, the interrupt is generated when the FIFO is filled to the trigger level selected in the FIFO control register (FCR), and it is cleared when the FIFO contents drop below the trigger level.

30.4.4.2.5.3 FIFO Modes

The following two modes can be used for servicing the receiver and transmitter FIFOs:

- FIFO interrupt mode. The FIFO is enabled and the associated interrupts are enabled. Interrupts are sent to the CPU to indicate when specific events occur.
- FIFO poll mode. The FIFO is enabled but the associated interrupts are disabled. The CPU polls status bits to detect specific events.

Because the receiver FIFO and the transmitter FIFO are controlled separately, either one or both can be placed into the interrupt mode or the poll mode.

30.4.4.2.5.3.1 FIFO Interrupt Mode

When the receiver FIFO is enabled in the FIFO control register (FCR) and the receiver interrupts are enabled in the interrupt enable register (IER), the interrupt mode is selected for the receiver FIFO. The following are important points about the receiver interrupts:

- The receiver data-ready interrupt is issued to the CPU when the FIFO has reached the trigger level that is programmed in FCR. It is cleared when the CPU or the DMA controller reads enough characters from the FIFO such that the FIFO drops below its programmed trigger level.
- The receiver line status interrupt is generated in response to an overrun error, a parity error, a framing error, or a break. This interrupt has higher priority than the receiver data-ready interrupt. For details, see Section 30.4.4.2.8.
- The data-ready (DR) bit in the line status register (LSR) indicates the presence or absence of characters in the receiver FIFO. The DR bit is set when a character is transferred from the receiver shift register (RSR) to the empty receiver FIFO. The DR bit remains set until the FIFO is empty again.
- A receiver time-out interrupt occurs if all of the following conditions exist:
  - At least one character is in the FIFO,
  - The most recent character was received more than four continuous character times ago. A character time is the time allotted for 1 START bit, *n* data bits, 1 PARITY bit, and 1 STOP bit, where *n* depends on the word length selected with the WLS bits in the line control register (LCR). See Table 30-36.
  - The most recent read of the FIFO has occurred more than four continuous character times before.
- Character times are calculated by using the baud rate.
- When a receiver time-out interrupt has occurred, it is cleared and the time-out timer is cleared when the CPU or the EDMA controller reads one character from the receiver FIFO. The interrupt is also cleared if a new character is received in the FIFO or if the URRST bit is cleared in the power and emulation management register (PWREMU_MGMT).
- If a receiver time-out interrupt has not occurred, the time-out timer is cleared after a new character is received or after the CPU or EDMA reads the receiver FIFO.

When the transmitter FIFO is enabled in FCR and the transmitter holding register empty (THRE) interrupt is enabled in IER, the interrupt mode is selected for the transmitter FIFO. The THRE interrupt occurs when the transmitter FIFO is empty. It is cleared when the transmitter hold register (THR) is loaded (1 to 16 characters may be written to the transmitter FIFO while servicing this interrupt) or the interrupt identification register (IIR) is read.

Table 30-36. Character Time for Word Lengths

Word Length (*n*)	Character Time	Four Character Times
5	Time for 8 bits	Time for 32 bits
6	Time for 9 bits	Time for 36 bits
7	Time for 10 bits	Time for 40 bits
8	Time for 11 bits	Time for 44 bits

30.4.4.2.5.3.2 FIFO Poll Mode

When the receiver FIFO is enabled in the FIFO control register (FCR) and the receiver interrupts are disabled in the interrupt enable register (IER), the poll mode is selected for the receiver FIFO. Similarly, when the transmitter FIFO is enabled and the transmitter interrupts are disabled, the transmitter FIFO is in the poll mode. In the poll mode, the CPU detects events by checking bits in the line status register (LSR):

- The RXFIFOE bit indicates whether there are any errors in the receiver FIFO.
- The TEMT bit indicates that both the transmitter holding register (THR) and the transmitter shift register (TSR) are empty.
- The THRE bit indicates when THR is empty.
- The BI (break), FE (framing error), PE (parity error), and OE (overrun error) bits specify which error or errors have occurred.
- The DR (data-ready) bit is set as long as there is at least one byte in the receiver FIFO.

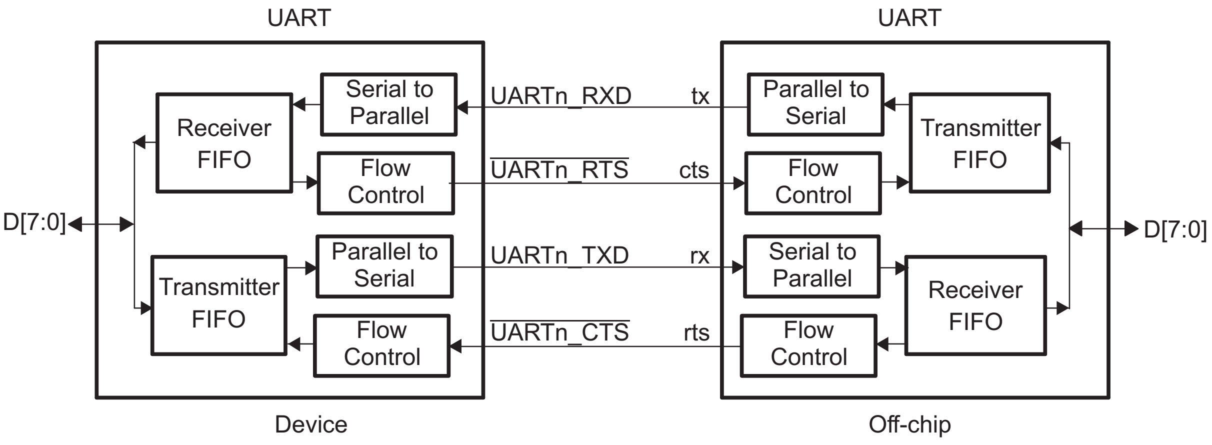
Also, in the FIFO poll mode:

- The interrupt identification register (IIR) is not affected by any events because the interrupts are disabled.
- The UART does not indicate when the receiver FIFO trigger level is reached or when a receiver time-out occurs.

30.4.4.2.5.4 Autoflow Control

The UART can employ autoflow control by connecting the UARTn_CTS and UARTn_RTS signals. Note that all UARTs do not support autoflow control; see your device-specific data manual for supported features. The UARTn_CTS input must be active before the transmitter FIFO can transmit data. The UARTn_RTS output becomes active when the receiver needs more data and notifies the sending device. When UARTn_RTS is connected to UARTn_CTS, data transmission does not occur unless the receiver FIFO has space for the data. Therefore, when two UARTs are connected as shown in Figure 30-35 with autoflow enabled, overrun errors are eliminated.

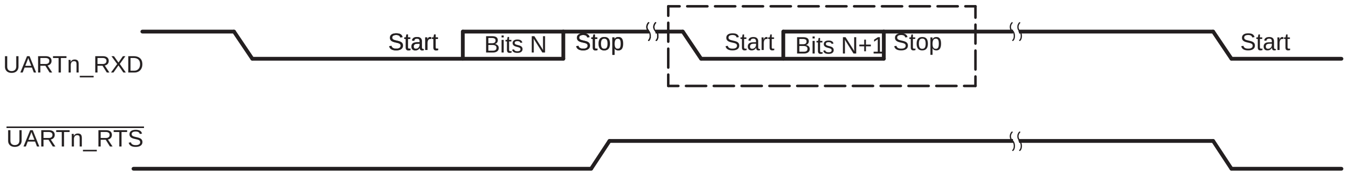
Figure 30-35. UART Interface Using Autoflow Diagram



30.4.4.2.5.4.1 UARTn_RTS Behavior

UARTn_RTS data flow control originates in the receiver block (see Figure 30-31). When the receiver FIFO level reaches a trigger level of 1, 4, 8, or 14 (see Figure 30-36), UARTn_RTS is deasserted. The sending UART may send an additional byte after the trigger level is reached (assuming the sending UART has another byte to send), because it may not recognize the deassertion of UARTn_RTS until after it has begun sending the additional byte. For trigger level 1, 4, and 8, UARTn_RTS is automatically reasserted once the receiver FIFO is emptied. For trigger level 14, UARTn_RTS is automatically reasserted once the receiver FIFO drops below the trigger level.

Figure 30-36. Autoflow Functional Timing Waveforms for UARTn_RTS



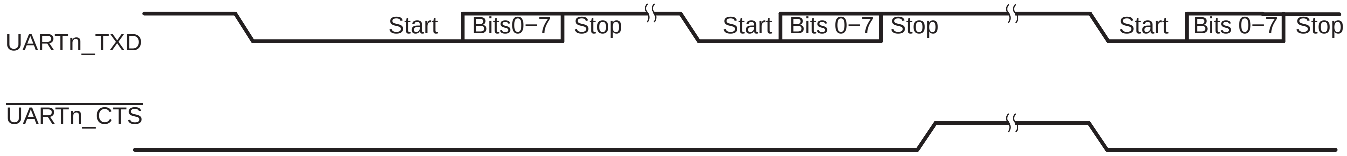
(1) N = Receiver FIFO trigger level.

(2) The block in dashed lines covers the case where an additional byte is sent.

30.4.4.2.5.4.2 UARTn_CTS Behavior

The transmitter checks UARTn_CTS before sending the next data byte. If UARTn_CTS is active, the transmitter sends the next byte. To stop the transmitter from sending the following byte, UARTn_CTS must be released before the middle of the last STOP bit that is currently being sent (see Figure 30-37). When flow control is enabled, UARTn_CTS level changes do not trigger interrupts because the device automatically controls its own transmitter. Without autoflow control, the transmitter sends any data present in the transmitter FIFO and a receiver overrun error may result.

Figure 30-37. Autoflow Functional Timing Waveforms for UARTn_CTS



(1) When UARTn_CTS is active (low), the transmitter keeps sending serial data out.

(2) When UARTn_CTS goes high before the middle of the last STOP bit of the current byte, the transmitter finishes sending the current byte but it does not send the next byte.

(3) When UARTn_CTS goes from high to low, the transmitter begins sending data again.

30.4.4.2.5.5 Loopback Control

The UART can be placed in the diagnostic mode using the LOOP bit in the modem control register (MCR), which internally connects the UART output back to the UART input. In this mode, the transmit and receive data paths, the transmitter and receiver interrupts, and the modem control interrupts can be verified without connecting to another UART.

30.4.4.2.6 Reset Considerations

30.4.4.2.6.1 Software Reset Considerations

Two bits in the power and emulation management register (PWREMU_MGMT) control resetting the parts of the UART:

- The UTRST bit controls resetting the transmitter only. If UTRST = 1, the transmitter is active; if UTRST = 0, the transmitter is in reset.
- The URRST bit controls resetting the receiver only. If URRST = 1, the receiver is active; if URRST = 0, the receiver is in reset.

In each case, putting the receiver and/or transmitter in reset will reset the state machine of the affected portion but does not affect the UART registers.

30.4.4.2.6.2 Hardware Reset Considerations

When the processor RESET pin is asserted, the entire processor is reset and is held in the reset state until the RESET pin is released. As part of a device reset, the UART state machine is reset and the UART registers are forced to their default states. The default states of the registers are shown in , *PRU_ICSS_UART Registers*.

30.4.4.2.7 Initialization

The following steps are required to initialize the UART:

1. Perform the necessary device pin multiplexing setup (see your device-specific data manual).
2. Set the desired baud rate by writing the appropriate clock divisor values to the divisor latch registers (DLL and DLH).
3. If the FIFOs will be used, select the desired trigger level and enable the FIFOs by writing the appropriate values to the FIFO control register (FCR). The FIFOEN bit in FCR must be set first, before the other bits in FCR are configured.
4. Choose the desired protocol settings by writing the appropriate values to the line control register (LCR).
5. If autoflow control is desired, write appropriate values to the modem control register (MCR). Note that all UARTs do not support autoflow control; see your device-specific data manual for supported features.
6. Choose the desired response to emulation suspend events by configuring the FREE bit, and enable the UART by setting the UTRST and URRST bits in the power and emulation management register (PWREMU_MGMT).

30.4.4.2.8 Interrupt Support

30.4.4.2.8.1 Interrupt Events and Requests

The UART generates the interrupt requests described in Table 30-37. All requests are multiplexed through an arbiter to a single UART interrupt request to the CPU, as shown in Figure 30-38. Each of the interrupt requests has an enable bit in the interrupt enable register (IER) and is recorded in the interrupt identification register (IIR).

If an interrupt occurs and the corresponding enable bit is set to 1, the interrupt request is recorded in IIR and is forwarded to the CPU. If an interrupt occurs and the corresponding enable bit is cleared to 0, the interrupt request is blocked. The interrupt request is neither recorded in IIR nor forwarded to the CPU.

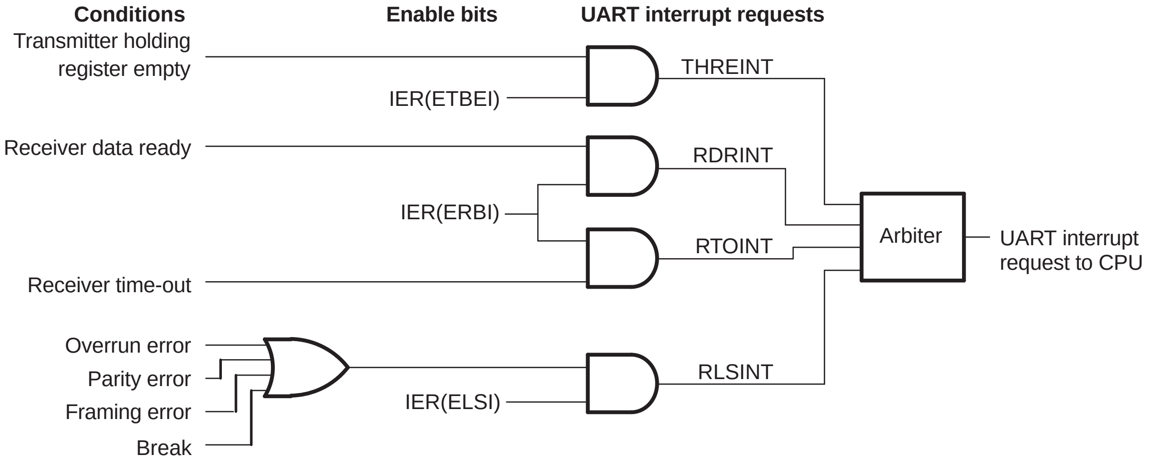
30.4.4.2.8.2 Interrupt Multiplexing

The UARTs have dedicated interrupt signals to the CPU and the interrupts are not multiplexed with any other interrupt source.

Table 30-37. UART Interrupt Requests Descriptions

UART Interrupt Request	Interrupt Source	Comment
THREINT	THR-empty condition: The transmitter holding register (THR) or the transmitter FIFO is empty. All of the data has been copied from THR to the transmitter shift register (TSR).	If THREINT is enabled in IER, by setting the ETBEI bit, it is recorded in IIR. As an alternative to using THREINT, the CPU can poll the THRE bit in the line status register (LSR).
RDAINT	Receive data available in non-FIFO mode or trigger level reached in the FIFO mode.	If RDAINT is enabled in IER, by setting the ERBI bit, it is recorded in IIR. As an alternative to using RDAINT, the CPU can poll the DR bit in the line status register (LSR). In the FIFO mode, this is not a functionally equivalent alternative because the DR bit does not respond to the FIFO trigger level. The DR bit only indicates the presence or absence of unread characters.
RTOINT	Receiver time-out condition (in the FIFO mode only): No characters have been removed from or input to the receiver FIFO during the last four character times (see Table 30-36), and there is at least one character in the receiver FIFO during this time.	The receiver time-out interrupt prevents the UART from waiting indefinitely, in the case when the receiver FIFO level is below the trigger level and thus does not generate a receiver data-ready interrupt. If RTOINT is enabled in IER, by setting the ERBI bit, it is recorded in IIR. There is no status bit to reflect the occurrence of a time-out condition.
RLSINT	Receiver line status condition: An overrun error, parity error, framing error, or break has occurred.	If RLSINT is enabled in IER, by setting the ELSI bit, it is recorded in IIR. As an alternative to using RLSINT, the CPU can poll the following bits in the line status register (LSR): overrun error indicator (OE), parity error indicator (PE), framing error indicator (FE), and break indicator (BI).

Figure 30-38. UART Interrupt Request Enable Paths



30.4.4.2.9 DMA Event Support

In the FIFO mode, the UART generates the following two DMA events:

- **Receive event (URXEVT):** The trigger level for the receiver FIFO (1, 4, 8, or 14 characters) is set with the RXFIFTL bit in the FIFO control register (FCR). Every time the trigger level is reached or a receiver time-out occurs, the UART sends a receive event to the EDMA controller. In response, the EDMA controller reads the data from the receiver FIFO by way of the receiver buffer register (RBR). Note that the receive event is not asserted if the data at the top of the receiver FIFO is erroneous even if the trigger level has been reached.
- **Transmit event (UTXEVT):** When the transmitter FIFO is empty (when the last byte in the transmitter FIFO has been copied to the transmitter shift register), the UART sends an UTXEVT signal to the EDMA controller. In response, the EDMA controller refills the transmitter FIFO by way of the transmitter holding register (THR). The UTXEVT signal is also sent to the DMA controller when the UART is taken out of reset using the UTRST bit in the power and emulation management register (PWREMU_MGMT).

Activity in DMA channels can be synchronized to these events. In the non-FIFO mode, the UART generates no DMA events. Any DMA channel synchronized to either of these events must be enabled at the time the UART event is generated. Otherwise, the DMA channel will miss the event and, unless the UART generates a new event, no data transfer will occur.

30.4.4.2.10 Power Management

The UART peripheral can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the UART peripheral is controlled by the processor Power and Clock Management (PRCM). The PRCM acts as a master controller for power management for all of the peripherals on the device. For detailed information on power management procedures using the PSC, see the chapter *Power, Reset, and Clock Management (PRCM)* in the device reference manual.

30.4.4.2.11 Emulation Considerations

The FREE bit in the power and emulation management register (PWREMU_MGMT) determines how the UART responds to an emulation suspend event such as an emulator halt or breakpoint. If FREE = 0 and a transmission is in progress, the UART halts after completing the one-word transmission; if FREE = 0 and a transmission is not in progress, the UART halts immediately. If FREE = 1, the UART does not halt and continues operating normally.

Note also that most emulator accesses are transparent to UART operation. Emulator read operations do not affect any register contents, status bits, or operating states, with the exception of the interrupt identification register (IIR). Emulator writes, however, may affect register contents and may affect UART operation, depending on which register is accessed and what value is written.

The UART registers can be read from or written to during emulation suspend events, even if the UART activity has stopped.

30.4.4.2.12 Exception Processing

30.4.4.2.12.1 Divisor Latch Not Programmed

Since the processor reset signal has no effect on the divisor latch, the divisor latch will have an unknown value after power up. If the divisor latch is not programmed after power up, the baud clock (BCLK) will not operate and will instead be set to a constant logic 1 state.

The divisor latch values should always be reinitialized following a processor reset.

30.4.4.2.12.2 Changing Operating Mode During Busy Serial Communication

Since the serial link characteristics are based on how the control registers are programmed, the UART will expect the control registers to be static while it is busy engaging in a serial communication. Therefore, changing the control registers while the module is still busy communicating with another serial device will most likely cause an error condition and should be avoided.

30.4.5 ECAP

The PRU ECAP module within the PRU-ICSS is identical to the ECAP module in the AM437x PWMSS. For additional details about the ECAP module, see Section 20.3, *Enhanced Capture (eCAP) Module*.

30.4.6 MII_RT

30.4.6.1 Introduction

The Real-time Media Independent Interface (MII_RT) provides a programmable I/O interface for the PRUs to access and control up to two MII ports. The MII_RT module can also be configured to push and pull data independent of the PRU cores.

NOTE: In order to guarantee the MII_RT IO timing values published in the device data manual, the ocp_clk must be configured for 200MHz (default value) and TXCFG<n>_TX_CLK_DELAY must be set to 6h (non-default value).

30.4.6.1.1 Features

The PRU-ICSS MII_RT module supports:

- Two MII ports
  - Each MII port has:
    - 32-byte RX L1 FIFO
    - 64-byte RX L2 buffer
    - 64-byte TX L1 FIFO
  - Rate decoupling on TX L1 FIFO
  - Configurable pre-amble removal on RX L1 FIFO and insertion on TX L1 FIFO
  - Configurable TX L1 FIFO trigger (10 bits with 40 ns ticks)
- MII port multiplexer per direction to support line/ring structure
  - Link detection through RX_ERR
- Cyclic redundancy check (CRC)
  - CRC32 generation on TX path
  - CRC32 checker on RX path

30.4.6.1.2 Unsupported Features

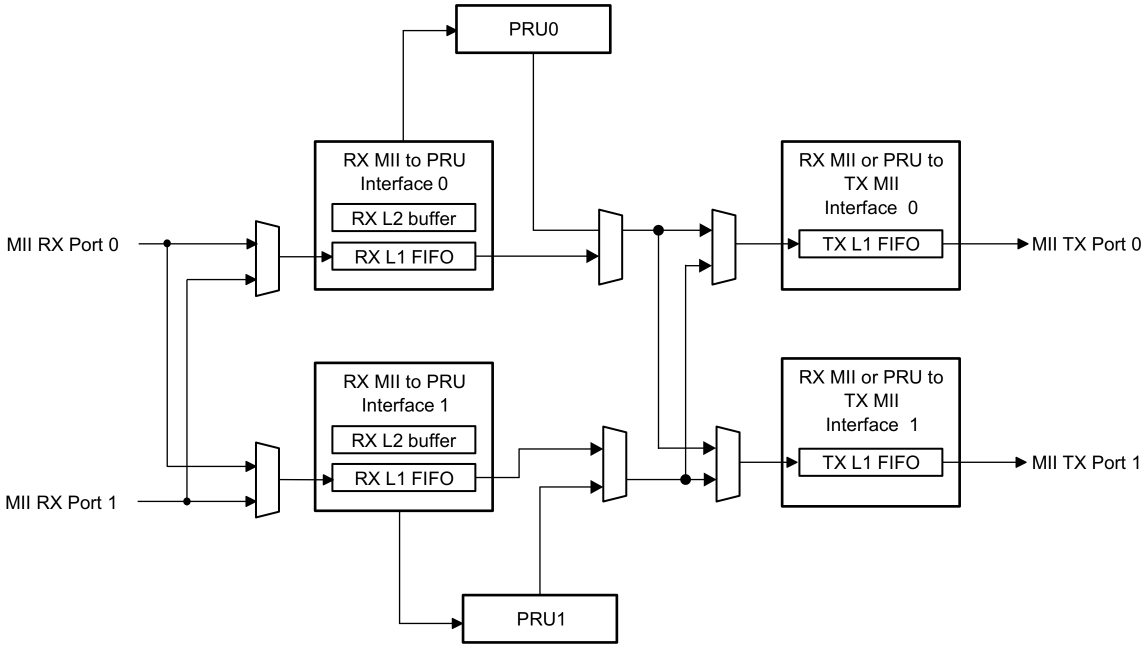
The PRU-ICSS MII_RT module does not support:

- Auto padding in TX L1 FIFO
- Dynamic TX multiplexer switching during packet handling
  - Can allow one PRU to handle both MII interfaces and a second PRU to manage the host and switch functions.

30.4.6.1.3 Block Diagram

Figure 30-39 shows the MII_RT in context of the PRU-ICSS. This diagram is a conceptual block diagram and does not necessarily reflect actual topologies.

Figure 30-39. MII_RT Block Diagram



30.4.6.2 Functional Description

30.4.6.2.1 Data Path Configuration

The MII_RT module supports three basic data path configurations. These configurations are compared in Table 30-38 and described in the following sections.

Table 30-38. Data Path Configuration Comparison

Configuration	PRU Dependency	Data Servicing	Port-to-Port Latency
Auto-forward	Snoop only	One word in flight	Low
8- or 16-bit processing with on-the-fly modifications (RX L1)	Yes	One word or byte in flight	Low
32-byte double buffer or ping-pong processing (RX L2)	Yes	Multi-words in flight	Medium (application-dependent)

30.4.6.2.1.1 Auto-forward with Optional PRU Snoop

Data is automatically forwarded from the MII RX port to the MII TX port without manipulations, as shown in Figure 30-40. This configuration does not depend on the PRU core. However, it does support an option for PRU to snoop or monitor the received data through the RX L2, shown in Figure 30-41. The PRU does not access data and status bits through R31, and it does not modify and push data.

Figure 30-40. Auto-forward

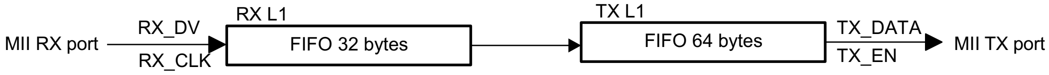


Figure 30-41. Auto-forward with PRU Snoop

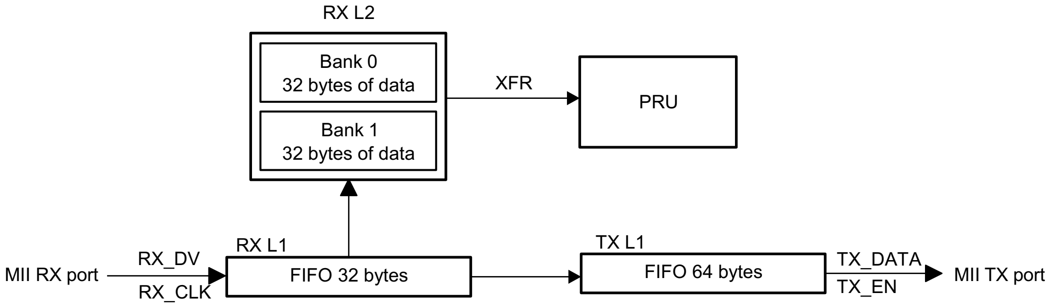
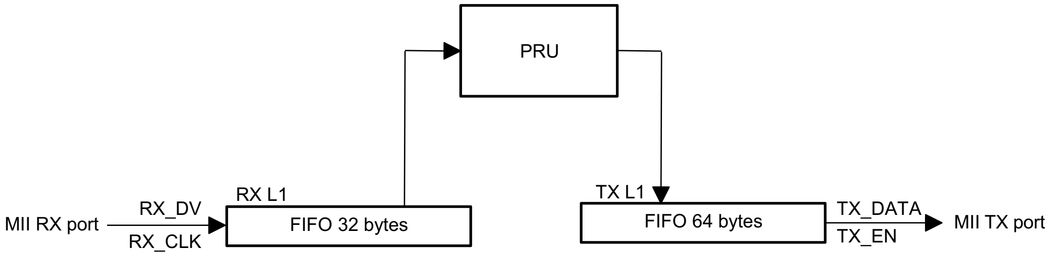


30.4.6.2.1.2 8- or 16-bit Processing with On-the-Fly Modifications

This configuration services one byte or word in flight and has low latency. The PRU has the option to manipulate the received word and control popping data from the RX L1 FIFO and pushing it on the TX L1 FIFO.

Figure 30-42. 8- or 16-bit Processing with On-the-Fly Modifications

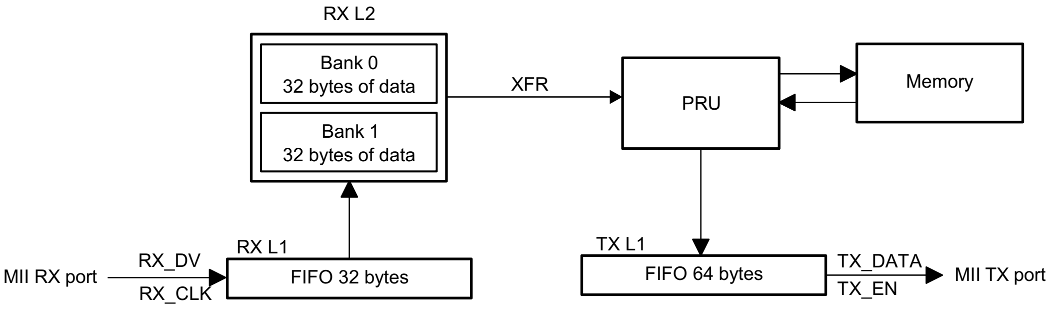


30.4.6.2.1.3 32-byte Double Buffer or Ping-Pong Processing

This configuration supports high bandwidth, high efficiency transactions. Often implementations using this mode permit relaxed servicing requirements allowing the PRU to manipulate the received data before transmitting.

Data received in this configuration is passed into the RX L2 buffer. The PRU reads multiple bytes of data from one of the RX L2 banks through the high bandwidth broadside interface and XFR instructions. The PRU can then store or manipulate data before pushing it to the TX L1 FIFO for transmission on the MII TX port.

Figure 30-43. 32-byte Double Buffer or Ping-Pong Processing



30.4.6.2.2 Definition and Terms

30.4.6.2.2.1 Data Frame Structure

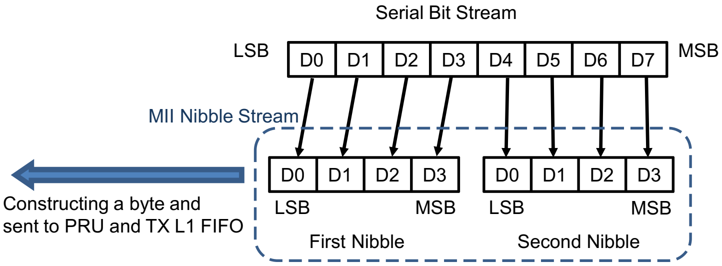
The data received and transmitted over MII conforms with the following frame structure:

Table 30-39. Frame Structure

Inter-frame	Preamble	Start of Frame Delimiter (SFD)	Data	Cyclic Redundancy Check (CRC)

The data following the SFD is formatted in a 4-bit nibble structure. Figure 30-44 illustrates the nibble order. The MSB arriving first is on the LSB side of a nibble. When receiving data, the MII_RT receive logic will wait for the next nibble to arrive before constructing a byte and delivering to the PRU.

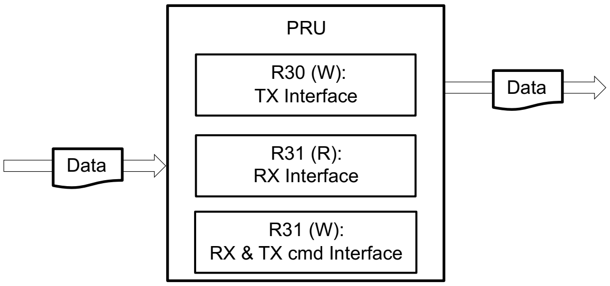
Figure 30-44. Data Nibble Structure



30.4.6.2.2.2 PRU R30 and R31

The PRU registers R30 and R31 are used to receive, transmit, and control the data for the PRU. As shown in Figure 30-45, the R31 is used to access data in the RX L1 FIFO, the R30 is used to transmit data from the PRU, and the R31 output is used the control the flow of receive and transmit. For more details about these registers, see the following sections.

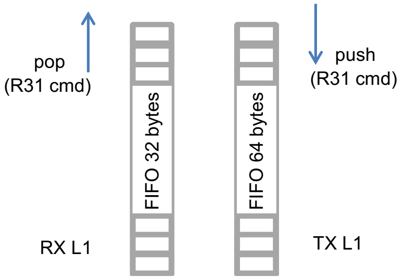
Figure 30-45. PRU R30, R31 Operations



30.4.6.2.2.3 RX and TX L1 FIFO Data Movement

To advance the next data byte seen by R31, the PRU must pop the data from the RX L1 FIFO. Likewise, the PRU can push the data from R30 to the TX L1 FIFO. These operations are illustrated in Figure 30-46.

Figure 30-46. Reading and Writing FIFO Data



30.4.6.2.2.4 CRC Computation

30.4.6.2.2.4.1 Receive CRC Computation

For the incoming data, the MII_RT calculates CRC32 and then compares against the value provided in the incoming frame. If there is a mismatch, the MII RT signals ERROR_CRC to the PRU. If a previous node or Ethernet device appended an error nibble, the CRC calculation of received packet will be wrong because the longer frame and the frame length will end at a 4-bit boundary instead of the usual 8-bit boundary. When RX_DV goes inactive on the 4-bit boundary, the interface will assert DATA_RDY and BYTE_RDY flag with the ERROR NIBBLE. The error event is also mapped into the PRU-ICSS INTC.

30.4.6.2.2.4.2 Transmit CRC Computation

For the outgoing data, the MII_RT calculates the CRC32 value and inserts it into outgoing packets. The CRC value computed on each MII transmit path is also available in memory map registers (MMRs) that can be read by the PRU and used primarily for debug and diagnostic purposes. The CRC is inserted into the outgoing packet based on the commands received through the R31 register of the PRU. The CRC will be inserted into the TX L1 FIFO, and there must be enough room to store the CRC value in the FIFO or else the FIFO will overflow. As Table 30-40 shows, the CRC programming model supports three sequences that provide more flexibility. Note “cmdR31” indicates write to the mentioned bits of the R31 command interface.

Table 30-40. TX CRC Programming Models

Option 1	Step 1: cmdR31 [TX_CRC_HIGH + TX_CRC_LOW + TX_EOF]
Option 2	Step 1: cmdR31 [TX_CRC_HIGH] Step 2: wait > 6 clocks (PRU cycles) Step 3: cmdR31 [TX_CRC_LOW + TX_EOF]
Option 3	Step 1: cmdR31 [TX_CRC_HIGH] Step 2: wait > 6 clocks (PRU cycles) Step 3: read TXCRC0/1 Step 4: modify CRC[15:0] Step 5: cmdR31 [TX_PUSH16 + TX_EOF + TX_ERROR_NIBBLE]

NOTE: If TX_AUTO_PREAMBLE = 1, then the first push of payload into the TX FIFO must be a byte push (TX_PUSH8). If the first push is a word (TX_PUSH16), then the CRC is not calculated correctly.

30.4.6.2.3 RX MII Interface

30.4.6.2.3.1 RX MII Submodule Overview

The RX MII interface is composed of multiple submodules that process the incoming frames and pass receive data and status information into the PRU register R31. These submodules include:

- Latch received data
- Start of frame detection
- Start frame delimiter detection
- CRC calculation and error detection
- Enhanced link detection through RX error detection

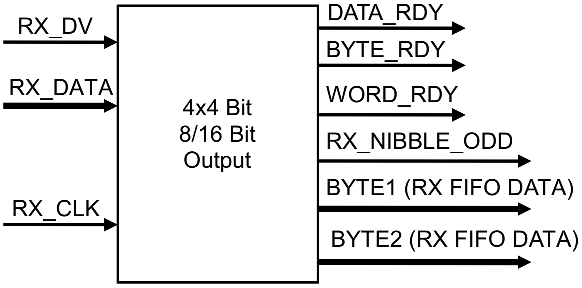
Table 30-41 includes more details about the internal signals and output of these submodules.

30.4.6.2.3.1.1 Receive Data Latch

The receive data from the MII interface is stored in the receive data FIFO which is 32 bytes. The PRU can access this data through the register R31. Depending on the configuration settings, the data can be latched on reception of one or two bytes. In each scheme, the configured number of nibbles is assembled before being copied into the PRU registers. Figure 30-47 shows the inputs and outputs of the data latch logic block.

The receiver logic in MII_RT can be programmed through the RXCFG0 and RXCFG1 registers to remove or retain the preamble + SFD from incoming frames.

Figure 30-47. RX Data Latch



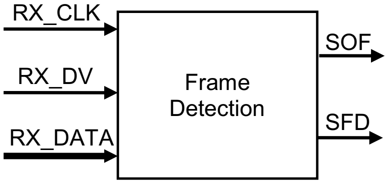
30.4.6.2.3.1.1.1 Start of Frame Detection

The start of frame detection logic tracks the frame boundaries and signals the beginning of a frame to other components of the PRU-ICSS. This logic detects two events:

- Start of Frame (SOF) event that occurs when Receive Data Valid MII signal is sampled high.
- Start of Frame Delimiter (SFD) event is seen on MII Receive Data bus.

These event triggers can be used to add timestamp to the frames. The notification for these events is available through R31 as well as through INTC which is integrated in the PRU-ICSS. Figure 30-48 shows the inputs and outputs of the start of frame detection logic block.

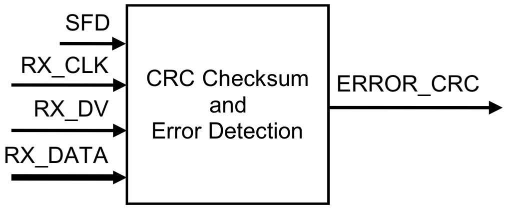
Figure 30-48. Start of Frame Detection



30.4.6.2.3.1.1.2 CRC Error Detection

For each incoming frame, the CRC is calculated by the MII_RT and compared against the CRC included in the frame. When the two values do not match, a CRC error is flagged. The ERROR_CRC indication is available in the register interface (PRU R31 Receive Interface) as well as in the FIFO interface (RX L2 Status Interface). It is also provided to the INTC which is integrated in the PRU-ICSS. Figure 30-49 shows the inputs and outputs of CRC error detection logic block.

Figure 30-49. CRC Error Detection

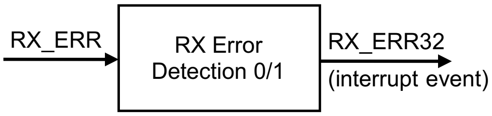


30.4.6.2.3.1.1.3 RX Error Detection and Action

The RX error detection logic tracks the receive error signaled by the physical layer and informs the PRU-ICSS INTC whenever an error is detected. Figure 30-50 shows the inputs and outputs of the RX error detection logic block. Note the following dependencies:

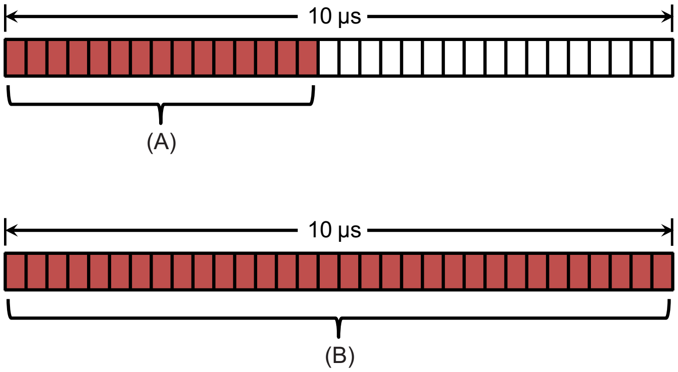
- RX_ERR signal is only sampled when RX_DV is asserted.
- All nibbles are discarded post RX_ERR event, including the nibble which had RX_ERR asserted. This state will remain until EOF occurs.
- Due to this fact, RX L1 FIFO and RX L2 FIFO will never receive any data with RX_ERR or post RX_ERR during that frame.

Figure 30-50. RX Error Detection



This submodule also keeps track of a running count of receive error events within a 10 µs error detection window, as shown in Figure 30-51. The INTC is notified when 32 or more events have occurred in a 10 µs error detection window. The error detection window is not a sliding window but a non-overlapping window with no specific initialization time with respect to incoming traffic. The timer starts its 10 µs counts immediately after de-assertion of reset to the MII_RT module.

Figure 30-51. Error Detection Window with Running Counter



A There are fewer than 32 consecutive error events in the 10 µs window. The detection module will not forward to the interrupt controller (INTC).

B There are more or equal to 32 error events in the 10 µs window. The detection module will notify the interrupt controller (INTC).

30.4.6.2.3.1.2 RX Data Path Options to PRU

There are two data path options for delivering received data to the PRU, described further in the subsequent sections:

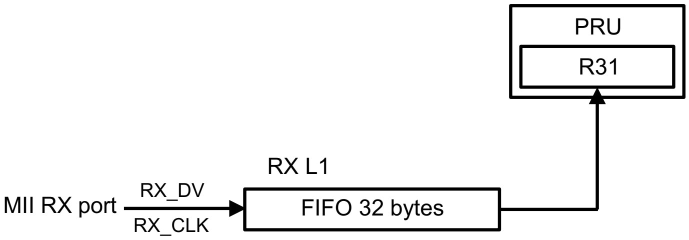
1. RX MII port → RX L1 FIFO → PRU (one word in flight)
2. RX MII port → RX L1 FIFO → RX L2 buffer → PRU (multi-word in flight)

Once the PRU has received RX data, the PRU can both manipulate received data or send data to the TX MII Interface.

30.4.6.2.3.1.2.1 RX MII Port → RX L1 FIFO → PRU

The RX L1 FIFO to PRU interface is depicted in Figure 30-52. In this mode, the data received from the MII interface is fed into the 32-byte RX L1 FIFO. The first data byte into the FIFO is automatically available in R31 of the PRU. Therefore, the PRU firmware can directly operate on this data without having to read it in a separate instruction. This allows the PRU to access receive data with low latency.

Figure 30-52. RX L1 to PRU Interface



When the new data is received, the PRU is provided with up to two bytes at a time in the R31 register, as shown in Figure 30-53. Once the PRU processes the incoming data, it instructs the MII_RT by writing to the R31 command interface bits to pop one or two bytes of data from the 32-byte RX FIFO. The pop operation causes current contents of R31 to be refreshed with new data from the incoming packet. Each time the data is popped, the status bits change to indicate so. If the pop is completed and there is no new data, the status bits immediately change to indicate no new data. Note the current R31 content, including data, will be lost after issuing the pop operation. If this information needs to be accessed later, the PRU should store the existing R31 content before popping new data.

Figure 30-53. MII RX Data to PRU R31 (R) and RX FIFO

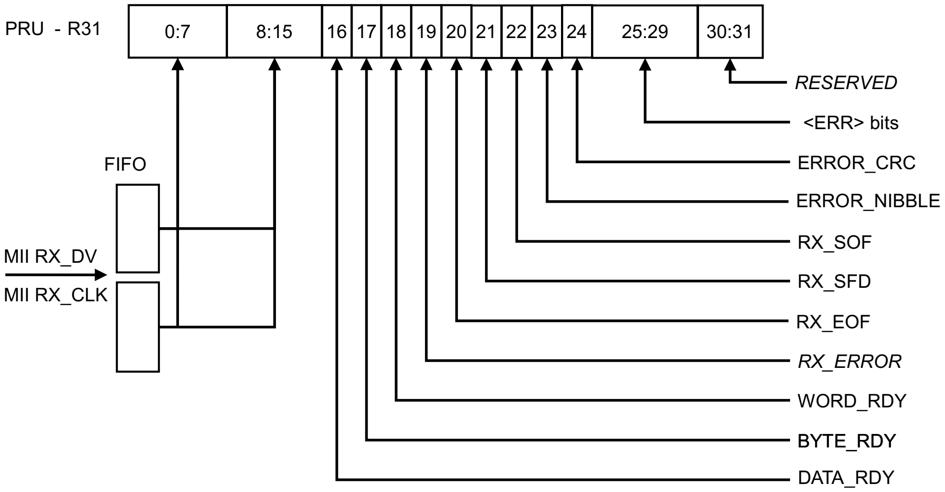


Table 30-41 describes the receive interface data and status contents provided by the R31 register. These contents are available when R31 is read. To configure this register, the PRU GPI mode should be set for MII_RT mode in the CFG register space. Note the following:

1. If the data from receive path is not read in time, it could cause an overflow event because the data is still continuously provided to the 32-byte receive FIFO. Due to the receive FIFO overflow, the data gets automatically discarded to avoid lack of space in the FIFO. At the same time, an interrupt is raised to the INTC through a system event (PRU<n>_RX_OVERFLOW). To detect an overflow condition, the PRU should poll for this system event condition and a RX RESET command through the R31 command interface is required to clear out from this condition. Note that the received Ethernet frame is corrupted and should not be used for further processing as bytes have been dropped due to the overflow condition. A FIFO reset is recommended.
2. The receive data in the R31 register is available following synchronization to the PRU clock domain. So, there is a finite delay (120 ns) when data is available from MII interface and it is accessible to the PRU.
3. The receive FIFO also has the capability to be reset through software. When reset, all contents of receive FIFO are purged and it may result in the current frame not being received as expected. When a frame is being received and the PRU resets the RX FIFO, the remaining frame is not placed into the RX FIFO. However, any new frame arriving on the receive MII port will be stored in the FIFO.

Table 30-41. PRU R31: Receive Interface Data and Status (Read Mode)

Bits	Field Name	Description
31:30	RESERVED	In case of register interface, these bits are provided to PRU by other modules in PRU-ICSS. From the MII_RT module point of view, these bits are always zero.
29	RX_MIN_FRM_CNT_ERR	RX_MIN_FRM_CNT_ERR is set to 1 when the count of total bytes of incoming frame is less than the value defined by RX_MIN_FRM_CNT. RX_MIN_FRM_CNT_ERR is cleared by RX_ERROR_CLR.
28	RX_MAX_FRM_CNT_ERR	RX_MAX_FRM_CNT_ERR is set to 1 when the count of total bytes of incoming frame is more than the value defined by RX_MAX_FRM_CNT_ERR. RX_MAX_FRM_CNT_ERR is cleared by RX_ERROR_CLR.
27	RX_EOF_ERROR	RX_EOF_ERROR is set to 1 when an RX_EOF event or RX_ERROR event occurs. RX_EOF_ERROR is cleared by RX_ EOF_CLR and/or RX_ ERROR_CLR.
26	RX_MAX_PRE_CNT_ERR	RX_MAX_PRE_CNT_ERR is set to 1 when the number of nibbles equaling 0x5 before SFD event (0x5D) is more than the value defined by RXPCNT0/1 [RX_MAX_PRE_CNT]. RX_MAX_PRE_CNT_ERR is cleared by RX_ERROR_CLR.
25	RX_ERR	RX_ERR is set to 1 when pr1_mii0/1_rxer is asserted while pr1_mii0/1_rxdv bit is set. RX_ERR is cleared by RX_ERROR_CLR.
24	ERROR_CRC	ERROR_CRC indicates that the frame has a CRC mismatch. This bit is valid when the RX_EOF bit is set. It should be noted that ERROR_CRC bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO. ERROR_CRC is cleared by RX_ERROR_CLR.
23	ERROR_NIBBLE	ERROR_NIBBLE indicates that the frame ended in odd nibble. It should be considered valid only when the RX_EOF bit and pr1_mii0/1_rxdv are set. Nibble counter is enabled post SFD event. It should be noted that ERROR_NIBBLE bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO. ERROR_NIBBLE is cleared by RX_ERROR_CLR.
22	RX_SOF	RX_SOF transitions from low to high when the frame data starts to arrive and pr1_mii0/1_rxdv is asserted. Note there will be a small sync delay of 0ns – 5ns. The PRU must write one to this bit through the R31 command interface to clear it. The recommended time to clear this bit is at the end of frame (EOF). It should be noted that RX_SOF bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO.
21	RX_SFD	RX_SFD transitions from low to high when the SFD sequence (0x5D) post RX_SOF is observed on the receive MII data. The PRU must write one to this bit through the R31 command interface to clear it. The recommended time to clear this bit is at the end of frame (EOF). It should be noted that RX_SFD bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO.
20	RX_EOF	RX_EOF indicates that the frame has ended and pr1_mii0/1_rxdv is de-asserted. It also validates the CRC match bit. Note there will be a small sync delay of 0ns – 5ns. The PRU must write one to clear this bit in the R31 command interface at the end of the frame. It should be noted that RX_EOF bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO.
19	RX_ERROR	RX_ERROR indicates one or more of the following errors occurred: • RX_MAX/MIN_FRM_CNT_ERR • RX_MAX/MIN_PRE_CNT_ERR • RX_ERR RX_ERROR is cleared by RX_ERROR_CLR.
18	WORD_RDY	WORD_RDY indicates that all four nibbles in R31 have valid data. There is a 2 clock cycle latency from the command RX_POP16 to WORD_RDY update. Therefore, firmware needs to insure it does not read WORD_RDY until 2 clock cycles after RX_POP16.
17	BYTE_RDY	BYTE_RDY indicates that the lower two nibbles in R31 have valid data. There is a 2 clock cycle latency from the command RX_POP8 to BYTE_RDY update. Therefore, PRU firmware needs to insure it does not read BYTE_RDY until 2 clock cycles after RX_POP8.

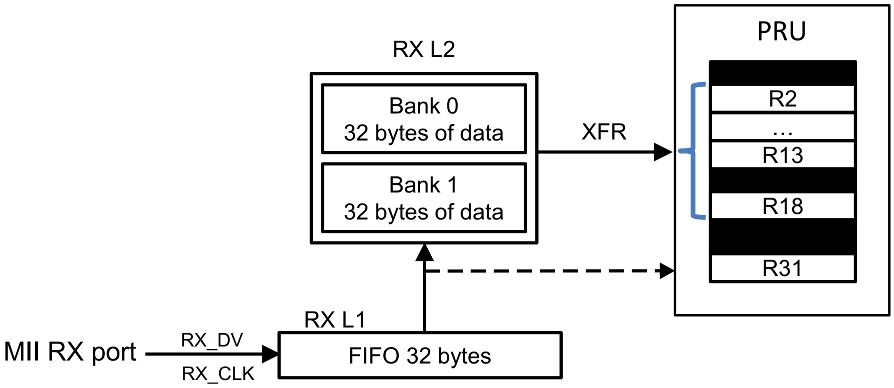
Table 30-41. PRU R31: Receive Interface Data and Status (Read Mode) (continued)

Bits	Field Name	Description
16	DATA_RDY	DATA_RDY indicates there is valid data in R31 ready to be read. This bit goes to zero when the PRU does a POP8/16 and there is no new data left in the receive MII port. This bit is high if there is more receive data for PRU to read. There is a 2 clock cycle latency from the command RX_POP16/8 to WORD_RDY/BYTE_RDY update. Therefore, PRU firmware needs to insure it does not read BYTE_RDY/WORD_RDY until 2 clock cycles after RX_POP16/8.
15:8	BYTE1	Data Byte 1. This data is available such that it is safe to read by the PRU when the DATA_RDY/BYTE_RDY/WORD_RDY bits are asserted.
7:0	BYTE0	Data Byte 0. This data is available such that it is safe to read by the PRU when the DATA_RDY/BYTE_RDY/WORD_RDY bits are asserted.

30.4.6.2.3.1.2.2 RX MII Port → RX L1 FIFO → RX L2 Buffer → PRU

The RX L2 is an optional high performance buffer between the RX L1 FIFO and the PRU. Figure 30-54 illustrates the receive data path using RX L2 buffer. This data path is characterized by multi-word in flight transactions.

Figure 30-54. RX L2 to PRU Interface



The 64-byte RX L2 buffer is divided into two 32 byte banks, or ping/pong buffers. When the RX L2 is enabled, the incoming data from the MII RX port will transmit first to the 32 byte RX L1 FIFO. RX L1 pushes data into RX L2, starting when the first byte is ready until the final EOF marker. The RX L2 buffer does not apply any backpressure to the RX L1 FIFO. Therefore, it is the PRU firmware’s responsibility to fetch the data in RX L2 before it is overwritten by the cyclic buffer. The RX L1 will remain near empty, with only one byte (nibble) stored.

Each RX L2 bank holds up to 32 bytes of data, and every four nibbles (or 16 bits) of data has a corresponding 8-bit status. The data and status information are stored in packed arrays. In each bank, R2 to R9 contains the data packed array and R10 to R13 contains the status packed array. Figure 30-55 shows the relationship of the data registers and status registers. The RX L2 status registers record status information about the received data, such as ERROR_CRC, RX_ERROR, STATUS_RDY, etc. The RX L2 status register details are described in Table 30-42. Note RX_RESET clears all Data and Status elements and resets R18.

Figure 30-55. Data and Status Register Dependency

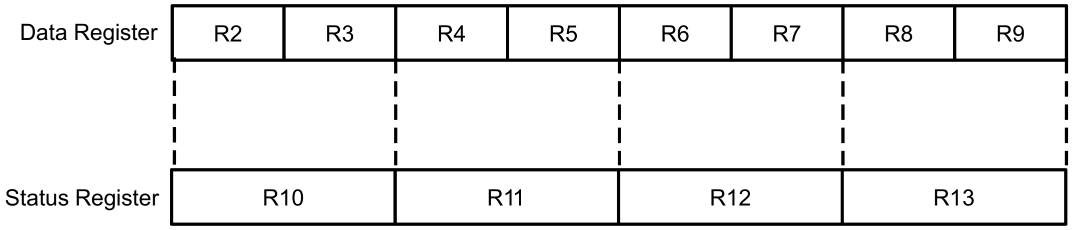


Table 30-42. RX L2 Status

Bit	Field Name	Description
7	ERROR_CRC	ERROR_CRC indicates that the frame has a CRC mismatch. This bit is valid when the RX_EOF bit is set. It should be noted that ERROR_CRC bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO. ERROR_CRC will only be set for one entry, self clear on next entry.
6	ERROR_NIBBLE	ERROR_NIBBLE indicates that the frame ended in odd nibble. It should be considered valid only when the RX_EOF bit and pr1_mii0/1_rxdv are set. Nibble counter is enabled post SFD event. It should be noted that ERROR_NIBBLE bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO. ERROR_NIBBLE will only be set for one entry, self clear on next entry.
5	RX_SOF	RX_SOF transitions from low to high when the frame data starts to arrive and pr1_mii0/1_rxdv is asserted. Note there will be a small sync delay of 0ns – 5ns. The recommended time to clear this bit is at the end of frame (EOF). It should be noted that RX_SOF bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO. RX_SOF will only be set for one entry, self clear on next entry.
4	RX_SFD	RX_SFD transitions from low to high when the SFD sequence (0x5D) post RX_SOF is observed on the receive MII data. The recommended time to clear this bit is at the end of frame (EOF). It should be noted that RX_SFD bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO. RX_SOF will only be set for one entry, self clear on next entry.
3	RX_EOF	RX_EOF indicates that the frame has ended and pr1_mii0/1_rxdv is de-asserted. It also validates the CRC match bit. Note there will be a small sync delay of 0ns – 5ns. It should be noted that RX_EOF bit is ready in early status, which means it is calculated before data is available in RXL1 FIFO. RX_EOF will only be set for one entry, self clear on next entry.
2	RX_ERROR	RX_ERROR indicates one or more of the following errors occurred: • RX_MAX/MIN_FRM_CNT_ERR • RX_MAX/MIN_PRE_CNT_ERR • RX_ERR RX_ERROR is cleared by RX_ERROR_CLR.
1	STATUS_RDY	STATUS_RDY is set when RX_EOF or write pointer advanced by 2. This is a simple method for software to determine if RX_EOF event has occurred or new data is available. If RX_EOF is not set, all status bits are static.
0	RX_ERR	RX_ERR is set to 1 when pr1_mii0/1_rxer is asserted while pr1_mii0/1_rxdv bit is set. It will get set for first pr1_mii0/1_rxer event and self clear on SOF for the next FRAME.

Bank 0 and Bank 1 are used as ping/pong buffers. RX L2 supports the reading of a write pointer in R18 that allows software to determine which bank has active write transactions, as well as the specific write address within packed data arrays.

The PRU interacts with the RX L2 buffer using the high performance XFR read instructions and broadside interface. Table 30-43 shows the device XFR ID numbers for each bank.

Table 30-43. RX L2 XFR ID

Device ID	Function	Description
20	Selects RX L2 Bank0	R2:R9 Data packed array R10:R13 Status packed array
21	Selects RX L2 Bank1	R2:R9 Data packed array R10:R13 Status packed array

Table 30-43. RX L2 XFR ID (continued)

Device ID	Function	Description
20/21	Byte pointer of current write	R18[5:0] Pointer indicating location of current write in data packed array. 0 = Bank0.R2.Byte0 (default and reset value) 1 = Bank0.R2.Byte1 2 = Bank0.R2.Byte2 3 = Bank0.R2.Byte3 4 = Bank0.R3.Byte0 … 63=Bank1.R9.Byte3

XFR read transactions are passive and have no effect on any status or other states in RX L2. The firmware can also read R18 to determine which Bank has active write transactions and the location of the transaction. With this information, the firmware can read multiple times the stable preserved data. Note when RX L1 data is written to RX L2, the next status byte gets cleared at the same time the current status byte gets updated. The rest of the status buffer is persistent. When software is accessing any register of the ping/ pong buffer, software needs to issue an XFER read transaction to fetch the latest/current state of the ping/pong buffer. The PRU registers will not reflect the current snapshot of L2 unless an XFER is issued by software.

30.4.6.2.4 TX MII Interface

Data to be transmitted is loaded into the TX L1 FIFO. The transmit FIFO (TX L1) stores up to 64 bytes of transmit data. From the FIFO, the data is sent to the MII TX port of the PHY by the MII_RT transmit logic.

The transmit FIFO also has the capability to be reset through software (TX_RESET). When reset, all contents of transmit FIFO are purged and this may result in a frame not getting transmitted as expected, if the transmission is already ongoing. Any new data written in the transmit FIFO results in a new frame being composed and transmitted. An overflow event will require a TX_RESET to recover from this condition.

There are four dependencies that must be true for TX_EN to assert.

1. TX L1 FIFO not empty
2. Interpacket gap (IPG) timer expiration
3. RX_DV to TX_EN timer expiration
4. TX_EN compare timer expiration

The transmit interface also provides an underflow error signal in case there was no data loaded when TX_EN triggered. The transmit underflow signal is mapped to the INTC in PRU-ICSS. The PRU firmware must track the FIFO fill level, such as by a timer or the PRU cycle count register (PRU_ICSS_CTRL_CYCLE).The current FIFO fill level cannot be accessed by PRU firmware. The firmware can issue an R31 command via R31 bit 29 (TX_EOF) to indicate that the last byte has been written into the TX FIFO.

30.4.6.2.4.1 TX Data Path Options to TX L1 FIFO

There are two data path options for delivering data to the TX L1 FIFO and transmit port, described further in the subsequent sections:

1. PRU → TX L1 FIFO → TX MII port
2. RX L1 FIFO → TX L1 FIFO → TX MII port

30.4.6.2.4.1.1 PRU → TX L1 FIFO → TX MII Port

The PRU can be used to feed data into the TX L1 FIFO using the R30 and R31 registers, shown in Figure 30-56. The PRU writes up to two bytes of data into R30 and then pushes the data into the TX L1 FIFO by writing to the R31 command interface.

Figure 30-56. PRU to TX L1 Interface

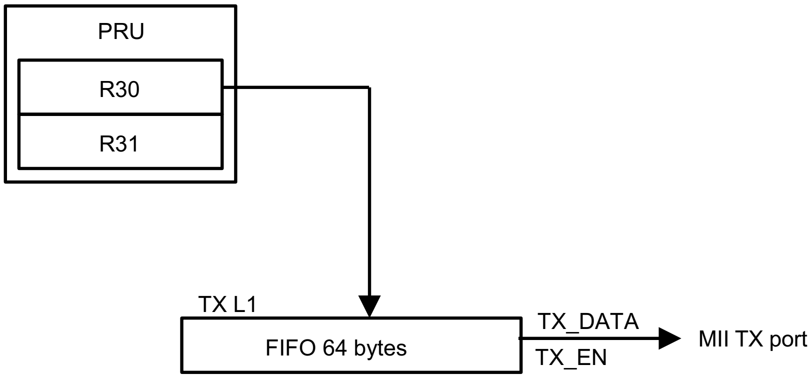

Figure 30-57 shows the R30 transmit interface. The lower 16 bits of the R30 (or FIFO transmit word) contain transmit data nibbles. The upper 16 bits contain mask information. The operation to be performed on the transmit interface is controlled by PRU writes to the R31 command interface. Table 30-44 describes the TXMASK and TXDATA bit fields of the R30 transmit interface.

Figure 30-57. PRU to TX MII Interface

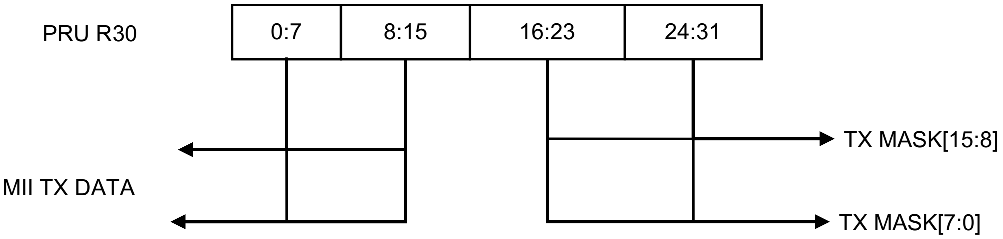

Table 30-44. PRU R30: Transmit Interface

Bits	Field Name	Description
31:16	TXMASK	The TXMASK is used to determine which of RX L1 FIFO received data and R30 data is sent to transmit FIFO. It must to be applied to TXDATA and RXDATA before it is transmitted. To disable TXMASK and transmit only TXDATA via R30, set to 0xFFFF. Note software should not pop the RXDATA from the RX L1 FIFO before pushing the TXDATA. This will cause new data to propagate before the push. Otherwise, software can pop and push on the same command for bytes only or delay the pop after the push for words or bytes.
15:0	TXDATA	Data provided by the PRU to be sent to transmit path after applying the mask. When 16 bits are to be transmitted, all bits of this and TXMASK field are used. When 8 bits are to be transmitted, the bits [7:0] of this and TXMASK field are used.

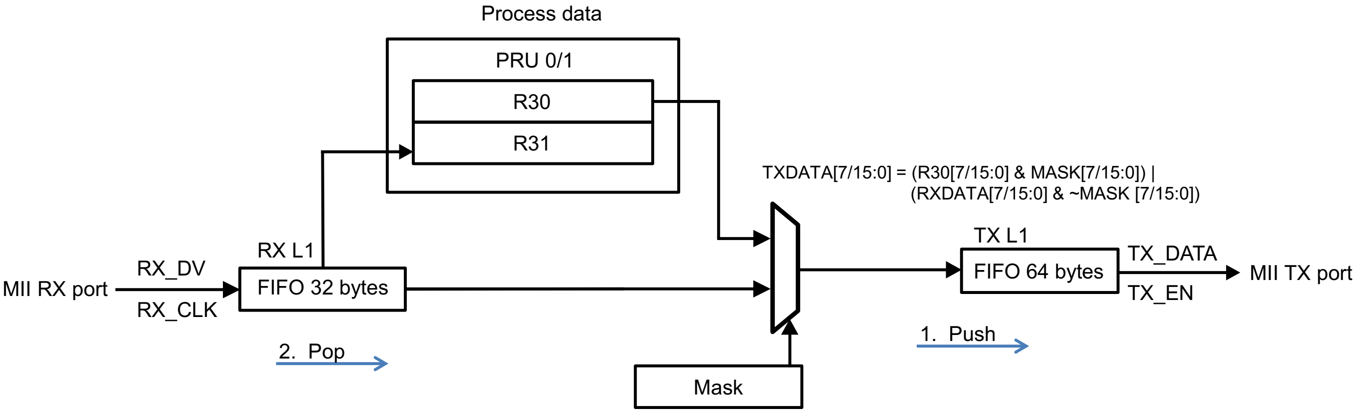
Using the TX mask, the PRU can send a mix of R30 and RX L1 FIFO data to the TX L1 FIFO. Note the TX mask is only available when the PRU is fed one word or byte at a time by the RX L1 FIFO. It is not applicable when the RX L2 buffer is enabled. To disable TX mask, set TXMASK to 0xFFFF.

As shown in Figure 30-58, the PRU drives the MII transmit interface through its R30 register. The contents of R30 and RX data from the receive interface are taken and fed into a 64 byte transmit FIFO.

Before transmission, a mask is applied to the data portion of the R30 register. By using the mask, the PRU firmware can control whether received data from the RX L1 FIFO is sent to transmit, R30 data is sent to transmit, or a mix of the two is sent. The Boolean equation that is used by MII_RT to compose TX data is:

TXDATA[7/15:0] = (R30[7/15:0] & MASK[7/15:0]) | (RXDATA[7/15:0] & ~MASK [7/15:0])

Figure 30-58. TX Mask Mode

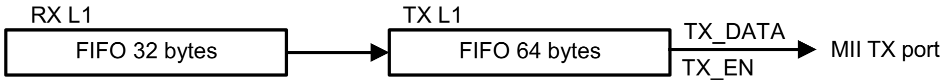


30.4.6.2.4.1.2 RX L1 FIFO → TX L1 FIFO → TX MII Port

When TXCFG0/1[TX_AUTO_SEQUENCE] is set, the data frame is passed from the RX to TX FIFOs without the any interaction of the PRU. This mode of operations is shown in Figure 30-59. The RX L1 will push into TX L1 as long as it is enabled and not full.

There is no PRU dependency in this mode and no option for the PRU to perform any operation to the TX L1 FIFO. RX_RESET clears all data and status elements.

Figure 30-59. RX L1 to TX L1 Interface



30.4.6.2.5 PRU R31 Command Interface

The PRU uses writes to R31[31:16] to control the reception and transmission of packets in register mode. Table 30-45 lists the available commands. Each bit in the table is a single clock pulse output from the PRU. When more than one action is to be performed in the same instant, the PRU firmware must set those command bits in one instruction.

Table 30-45. PRU R31: Command Interface (Write Mode)

Bit	Command	Description
31	TX_CRC_ERR	TX_CRC_ERR command when set will add 0xa5 byte to the TX L1 FIFO if the current FCS is valid. This bit can only be set with the TX_EOF command and optionally with the TX_ERROR_NIBBLE command. It cannot get set with any other commands. Note for proper operations auto-forward preamble must be enabled.
30	TX_RESET	TX_RESET command is used to reset the transmit FIFO and clear all its contents. This is required to recover from a TX FIFO overrun.
29	TX_EOF	TX_EOF command is used to indicate that the data loaded is considered last for the current frame
28	TX_ERROR_NIBBLE	TX_ERROR_NIBBLE command is used to insert an error nibble. This makes the frame invalid. Also, it will add 0x0 after the 32-bit CRC.
27	TX_CRC_HIGH	TX_CRC_HIGH command ends the CRC calculations and pushes CRC[31:16] to append to the outgoing frame in the TX L1 FIFO. Note TXCRC0/1 will become valid after 6 clock cycles.
26	TX_CRC_LOW	TX_CRC_LOW command pushes CRC[15:0] to append to the outgoing frame in the TX L1 FIFO.

Table 30-45. PRU R31: Command Interface (Write Mode) (continued)

Bit	Command	Description
25	TX_PUSH16	TX_PUSH16 command applies mask to two bytes from receive path and transmit. Note TX_PUSH16 needs to occur before TX_POP16 if data is not fully masked. TX CRC requires the data to be valid for 2 clock cycles.
24	TX_PUSH8	TX_PUSH8 command applies mask to one byte from receive path and transmit. Note TX_PUSH8 needs to occur before TX_POP8 if data is not fully masked.
23	RX_ ERROR_CLR	RX_ERROR_CLR command is used to clear RX_ ERROR indicator bit by writing 1.
22	RX_EOF_CLR	RX_EOF_CLR command is used to clear RX_EOF status indicator bit by writing 1.
21	RX_SFD_CLR	RX_SFD_CLR command is used to clear RX_SFD indicator bit by writing 1.
20	RX_SOF_CLR	RX_SOF_CLR command is used to clear RX_SOF indicator bit by writing 1.
19	Reserved	Reserved
18	RX_RESET	RX_RESET is used to reset the receive FIFO and clear all contents. This is required to recover from a RX FIFO overrun, if software does not want to undrain. The typical use case is assertion after RX_EOF. If asserted during an active frame, the following actions will occur: 1. Terminate the current frame 2. Block/terminate all new data 3. Flush/clear all FIFO elements 4. Cause RX state machine into an idle state 5. Cause EOF event 6. Cause minimum frame error, if you abort before minimum size reached
17	RX_POP16	RX_POP16 command advances the receive traffic by two bytes. This is only required when you are using R31 to read the data. After R31[15:0] is ready to read by PRU, it will set 1 to WORD_RDY, and the next new data will be allowed to advance. RX_POP16 to WORD_RDY update has 2 clock cycles latency. Firmware needs to insure it does not read WORD_RDY/BYTE_RDY until 2 clock cycles after RX_POP16.
16	RX_POP8	RX_POP8 command advances the receive traffic by one bytes. This is only required when you are using R31 to read the data. After R31[7:0] is ready to read by PRU, it will set 1 to BYTE_RDY, and the next new data will be allowed to advance. RX_POP8 to BYTE_RDY update has 2 clock cycles latency. Firmware needs to insure it does not read WORD_RDY/BYTE_RDY until 2 clock cycles after RX_POP8.

30.4.6.2.6 Other Configuration Options

30.4.6.2.6.1 Nibble and Byte Order

The PRU core is little endian. To support big endian, the MII_RT supports optional nibble swapping on both the RX and TX side.

On the receive side, the order of the two data bytes in RX R31 and the RX L2 buffer are configurable through the RX_BYTE_SWAP bit in the RXCFG0/1 registers, as shown in Table 30-46. Note the Nibble0 is the first nibble received.

Table 30-46. RX Nibble and Byte Order

Configuration	Order
RXCFG0/1[RX_BYTE_SWAP] = 0 (default)	R31[15:8] / RXL2[15:8] = Byte1{Nibble3,Nibble2} R31[7:0] / RXL2[7:0] = Byte0{Nibble1,Nibble0}

Table 30-46. RX Nibble and Byte Order (continued)

Configuration	Order
RXCFG0/1[RX_BYTE_SWAP] = 1	R31[15:8] / RXL2[15:8] = Byte0{Nibble1,Nibble0} R31[7:0] / RXL2[7:0] = Byte1{Nibble3,Nibble2}

On the transmit side, the order of the two data bytes and mask bytes in TX R30 are configurable through the TX_BYTE_SWAP bit in the TXCFG0/1 registers, as shown in Table 30-47. Note the Nibble0 is the first nibble received.

Table 30-47. TX Nibble and Byte Order

Configuration	Order
TXCFG0/1[TX_BYTE_SWAP] = 0 (default)	R30[15:8] = Byte1{Nibble3,Nibble2} R30[7:0] = Byte0{Nibble1,Nibble0} R30[31:24] = TX_MASK[15:8] R30[23:16] = TX_MASK[7:0]
TXCFG0/1[TX_BYTE_SWAP] = 1	R30[15:8] = Byte0{Nibble1,Nibble0} R30[7:0] = Byte1{Nibble3,Nibble2} R30[31:24] = TX_MASK[7:0] R30[23:16] = TX_MASK[15:8]

30.4.6.2.6.2 Preamble Source

The MII_RT module has the option to preserve and forward a received preamble in the TX data stream, use a preamble provided by the PRU, or auto-generate a preamble. These configurations are highlighted in Table 30-48.

Table 30-48. Preamble Configuration Options

RX_CUT_PREAMBLE	Determines whether RX preamble is passed to the RX L1/L2 FIFO
RX_AUTO_FWD_PRE	Determines whether RX preamble is automatically passed to TX L1 FIFO
TX_AUTO_PREAMBLE	TX interface logic auto-generates and appends preamble to TX data stream with the first push of data into the TX L1 FIFO. Note that enabling this option does fill the TX FIFO with the preamble length, hence software has to consider this to not overrun the TX FIFO.

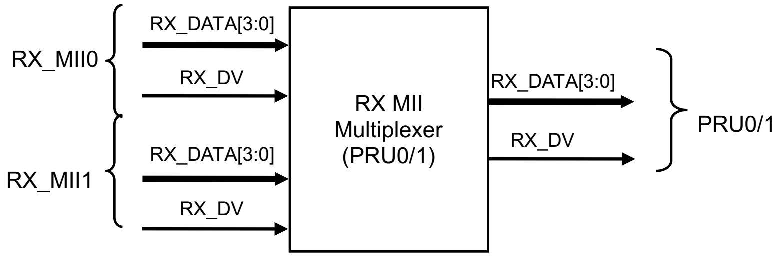
30.4.6.2.6.3 PRU and MII Port Multiplexer

The MII_RT module supports configurable PRU core to MII TXn / RXn port mapping. By default, PRU0 is mapped to TX1 and RX0 and PRU1 is mapped to TX0 and RX1. However, the system supports the flexibility to map any PRU core to any TX and RX port. Note the mapping options are destination fixed. For example, the input to PRU0 can be either RX_MII0 or RX_MII1. Similarly, the input to TX_MII0 can be either PRU0 or PRU1.

30.4.6.2.6.3.1 Receive Multiplexer

A multiplexer is provided to allow selecting either of the two MII interfaces for the receive data that is sent to PRU. Figure 30-60 shows the symbol of receive multiplexer of PRU.

Figure 30-60. MII Receive Multiplexer

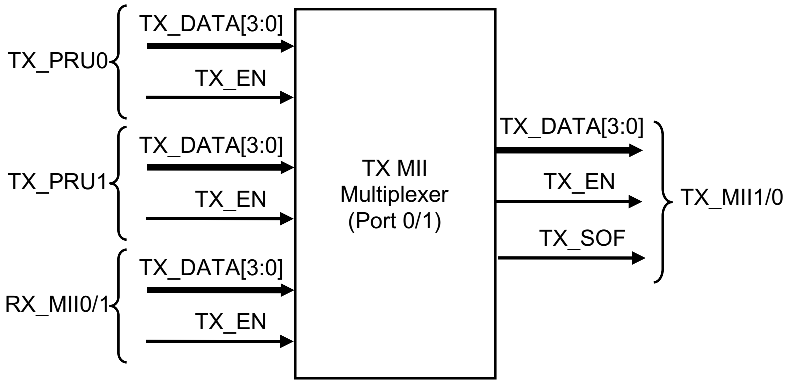


There are two receive multiplexer instances to enable selection of RX MII path for each PRU. The select lines of the RX multiplexers are driven from the PRU-ICSS programmable registers (RXCFG0/1).

30.4.6.2.6.3.2 Transmit Multiplexer

On the MII transmit ports, there is a multiplexer for each MII transmit port that enables selection of either the transmit data from the PRUs or from the RX MII interface of the other MII interface. Figure 30-61 shows the symbol of transmit multiplexer of PRU.

Figure 30-61. MII Transmit Multiplexer

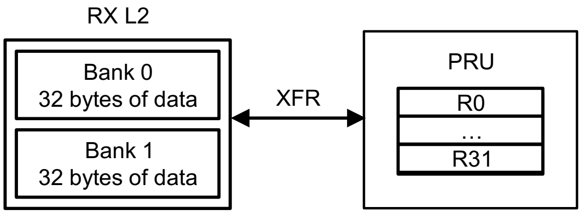


The transmit multiplexers enable the PRU-ICSS to either operate in a bypass mode where the PRU is not involved in processing MII traffic or use of one of the PRU cores for transmitting data into the MII interface. There are two instances of the TX MII multiplexer and the select lines for each TX multiplexer are provided by the PRU-ICSS. The select lines are common between register and FIFO interface. It is expected that the select lines will not change during the course of a frame so that can avoid data exchange error.

30.4.6.2.6.4 RX L2 Scratch Pad

When the RX L2 is disabled (RXCFG0/1[RX_L2_ENABLE] = 0), the RX L2 banks can be used as a generic scratch pad. In scratch pad mode, RX L2 Bank0 and RX L2 Bank1 operate like simple write/read memory mapped registers (MMRs). All XFR size and start operations are supported. RX_RESET has no effect in this mode. This mode is shown in Figure 30-62.

Figure 30-62. Scratch Pad Mode



30.4.6.3 Interrupts

The MII_RT tracks multiple events that could lead to generation of interrupt to the INTC which integrated in PRU-ICSS. These events are classified into receive, transmit and MII link events. Each event can occur on either of the two MII interfaces. Table 30-49 lists all interrupts from MII_RT to PRU-ICSS INTC module. Note All events to INTC are pulse type.

Table 30-49. Interrupt Events in MII_RT

Index	Name	Description
0	PRU0_RX_ERR	Error occurs on receive packet attached to PRU0.
1	PRU0_RX_ERR32	There are over 32 errors in a 10us window on receive packets attached to PRU0.
2	PRU0_RX_SFD	Start of frame delimiter detects 0x5D event attached to PRU0.
3	PRU0_RX_SOF	Start of frame detects event attached to PRU0.
4	PRU0_RX_CRC	CRC mismatch error occurs on receive packet attached to PRU0.
5	PRU0_RX_NIBBLE_ODD	There are odd nibbles in a received frame attached to PRU0.
6	PRU0_RX_OVERFLOW	RX L1 FIFO is overflows attached to PRU0.
7	PORT0_TX_UNDERFLOW	TX L1 FIFO is underflow attached to PORT0.
8	PORT0_TX_OVERFLOW	TX L1 FIFO is overflow attached to PORT0.
9	PORT0_MII_LINK	PHY link Interrupt attached to PORT0.
10	PRU0_RX_EOF	End of frame detects event attached to PRU0.
11	RESERVED	Reserved
12	PRU1_RX_ERR	Error occurs on receive packet attached to PRU1.
13	PRU1_RX_ERR32	There are over 32 errors in a 10us window on receive packets attached to PRU1.
14	PRU1_RX_SFD	Start of frame delimiter detects 0x5D event attached to PRU1.
15	PRU1_RX_SOF	Start of frame detects event attached to PRU1.
16	PRU1_RX_CRC	CRC mismatch error occurs on receive packet attached to PRU1.
17	PRU1_RX_NIBBLE_ODD	There are odd nibbles in a received frame attached to PRU1.
18	PRU1_RX_OVERFLOW	RX L1 FIFO is overflows attached to PRU1.
19	PORT1_TX_UNDERFLOW	TX L1 FIFO is underflow attached to PORT1.
20	PORT1_TX_OVERFLOW	TX L1 FIFO is overflow attached to PORT1.
21	PORT1_MII_LINK	PHY link Interrupt attached to PORT1.
22	PRU1_RX_EOF	End of frame detects event attached to PRU1.
23	RESERVED	Reserved

30.4.7 MDIO

The MDIO module within the PRU-ICSS is identical to the MDIO module in the AM437xAM437x Ethernet Subsystem. For additional details about the MDIO module, see Section 15.3.8, *MDIOAM437x ARM® Cortex™-A9 Processors Technical Reference Manual* (SPRUHL7)..

30.5 Registers

30.5.1 PRU_ICSS_PRU_CTRL Registers

Table 30-50 lists the memory-mapped registers for the PRU_ICSS_PRU_CTRL. All register offset addresses not listed in Table 30-50 should be considered as reserved locations and the register contents should not be modified.

Table 30-50. PRU_ICSS_PRU_CTRL REGISTERS

Offset	Acronym	Register Name	Section
0h	PRU_ICSS_CTRL		Section 30.5.1.1
4h	PRU_ICSS_CTRL_STS		Section 30.5.1.2

R/W-0h				R/W-0h	R/W-0h	R/W-0h	R/W-1h

Table 30-51. PRU_ICSS_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	PCTR_RST_VAL	R/W	0h	Program Counter Reset Value: This field controls the address where the PRU will start executing code from after it is taken out of reset.
15	RUNSTATE	R	0h	Run State: This bit indicates whether the PRU is currently executing an instruction or is halted. This bit is used by an external debug agent to know when the PRU has actually halted when waiting for a HALT instruction to execute, a single step to finish, or any other time when the pru_enable has been cleared. 0h (R/W) = PRU is halted and host has access to the instruction RAM and debug registers regions. 1h (R/W) = PRU is currently running and the host is locked out of the instruction RAM and debug registers regions.
14	RESERVED	R	0h	Reserved.
13-9	RESERVED	R/W	0h	
8	SINGLE_STEP	R/W	0h	Single Step Enable: This bit controls whether or not the PRU will only execute a single instruction when enabled. Note that this bit does not actually enable the PRU, it only sets the policy for how much code will be run after the PRU is enabled. The pru_enable bit must be explicitly asserted. It is legal to initialize both the SINGLE_STEP and EN bits simultaneously. (Two independent writes are not required to cause the stated functionality.) 0h (R/W) = PRU will free run when enabled. 1h (R/W) = PRU will execute a single instruction and then the pru_enable bit will be cleared.
7-4	RESERVED	R/W	0h	
3	CTR_EN	R/W	0h	PRU Cycle Counter Enable: Enables PRU cycle counters. 0h (R/W) = Counters not enabled 1h (R/W) = Counters enabled
2	SLEEPING	R/W	0h	PRU Sleep Indicator: This bit indicates whether or not the PRU is currently asleep. 0h (R/W) = PRU is not asleep 1h (R/W) = PRU is asleep; If this bit is written to a 0, the PRU will be forced to power up from sleep mode.

Table 30-51. PRU_ICSS_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	EN	R/W	0h	Processor Enable: This bit controls whether or not the PRU is allowed to fetch new instructions. If this bit is de-asserted while the PRU is currently running and has completed the initial cycle of a multi-cycle instruction (LBxO, SBxO, etc.), the current instruction will be allowed to complete before the PRU pauses execution. Otherwise, the PRU will halt immediately. Because of the unpredictability/timing sensitivity of the instruction execution loop, this bit is not a reliable indication of whether or not the PRU is currently running. The pru_state bit should be consulted for an absolute indication of the run state of the core. When the PRU is halted, its internal state remains coherent therefore this bit can be reasserted without issuing a software reset and the PRU will resume processing exactly where it left off in the instruction stream. 0h (R/W) = PRU is disabled. 1h (R/W) = PRU is enabled.
0	SOFT_RST_N	R/W	1h	Soft Reset: When this bit is cleared, the PRU will be reset. This bit is set back to 1 on the next cycle after it has been cleared.

30.5.1.2 PRU_ICSS_CTRL_STS Register (offset = 4h) [reset = 0h]

PRU_ICSS_CTRL_STS is shown in Figure 30-64 and described in Table 30-52.

STATUS REGISTER

<tr><td colspan="32">R/W-0h</td></tr>
</table>

Table 30-53. PRU_ICSS_CTRL_WAKEUP_EN Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	BITWISE_ENS	R/W	0h	Wakeup Enables: This field is ANDed with the incoming R31 status inputs (whose bit positions were specified in the stmap parameter) to produce a vector which is unary ORed to produce the status_wakeup source for the core. Setting any bit in this vector will allow the corresponding status input to wake up the core when it is asserted high. The PRU should set this enable vector prior to executing a SLP (sleep) instruction to ensure that the desired sources can wake up the core.

30.5.1.4 PRU_ICSS_CTRL_CYCLE Register (offset = Ch) [reset = 0h]

PRU_ICSS_CTRL_CYCLE is shown in Figure 30-66 and described in Table 30-54.

CYCLE COUNT. This register counts the number of cycles for which the PRU has been enabled.

Figure 30-66. PRU_ICSS_CTRL_CYCLE Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CYCLECOUNT																															
0h																															

Table 30-54. PRU_ICSS_CTRL_CYCLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	CYCLECOUNT		0h	This value is incremented by 1 for every cycle during which the PRU is enabled and the counter is enabled (both bits ENABLE and COUNTENABLE set in the PRU control register). Counting halts while the PRU is disabled or counter is disabled, and resumes when re-eneabled. Counter clears the COUNTENABLE bit in the PRU control register when the count reaches 0xFFFFFFFF. (Count does does not wrap). The register can be read at any time. The register can be cleared when the counter or PRU is disabled. Clearing this register also clears the PRU Stall Count Register.

30.5.1.5 PRU_ICSS_CTRL_STALL Register (offset = 10h) [reset = 0h]

PRU_ICSS_CTRL_STALL is shown in Figure 30-67 and described in Table 30-55.

STALL COUNT. This register counts the number of cycles for which the PRU has been enabled, but unable to fetch a new instruction. It is linked to the Cycle Count Register (0x0C) such that this register reflects the stall cycles measured over the same cycles as counted by the cycle count register. Thus the value of this register is always less than or equal to cycle count.

<tr><td colspan="32">0h</td></tr>
</table>

Table 30-55. PRU_ICSS_CTRL_STALL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	STALLCOUNT		0h	This value is incremented by 1 for every cycle during which the PRU is enabled and the counter is enabled (both bits ENABLE and COUNTENABLE set in the PRU control register), and the PRU was unable to fetch a new instruction for any reason.

30.5.1.6 PRU_ICSS_CTRL_CTBIR0 Register (offset = 20h) [reset = 0h]

PRU_ICSS_CTRL_CTBIR0 is shown in Figure 30-68 and described in Table 30-56.

CONSTANT TABLE BLOCK INDEX REGISTER 0. This register is used to set the block indices which are used to modify entries 24 and 25 in the PRU Constant Table. This register can be written by the PRU whenever it needs to change to a new base pointer for a block in the State / Scratchpad RAM. This function is useful since the PRU is often processing multiple processing threads which require it to change contexts. The PRU can use this register to avoid requiring excessive amounts of code for repetitive context switching. The format of this register is as follows:

Figure 30-68. PRU_ICSS_CTRL_CTBIR0 Register

15-8	RESERVED	R/W	0h	
7-0	C26_BLK_IDX	R/W	0h	PRU Constant Entry 26 Block Index: This field sets the value that will appear in bits 11 to 8 of entry 26 in the PRU Constant Table.

30.5.1.8 PRU_ICSS_CTRL_CTPPR0 Register (offset = 28h) [reset = 0h]

PRU_ICSS_CTRL_CTPPR0 is shown in Figure 30-70 and described in Table 30-58.

CONSTANT TABLE PROGRAMMABLE POINTER REGISTER 0. This register allows the PRU to set up the 256-byte page index for entries 28 and 29 in the PRU Constant Table which serve as general purpose pointers which can be configured to point to any locations inside the session router address map. This register is useful when the PRU needs to frequently access certain structures inside the session router address space whose locations are not hard coded such as tables in scratchpad memory. This register is formatted as follows:

Figure 30-70. PRU_ICSS_CTRL_CTPPR0 Register

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>

Bit	Field	Type	Reset	Description
31-0	GP_REG29	R/W	0h	PRU Internal GP Register n: Reading / writing this field directly inspects/modifies the corresponding internal register in the PRU internal regfile.

30.5.2.31 PRU_ICSS_DBG_GPREG30 Register (offset = 78h) [reset = 0h]

PRU_ICSS_DBG_GPREG30 is shown in Figure 30-102 and described in Table 30-91.

DEBUG PRU GENERAL PURPOSE REGISTER 30. This register allows an external agent to debug the PRU while it is disabled. Reading or writing to these registers will have the same effect as a read or write to these registers from an internal instruction in the PRU. For R30, this includes generation of the pulse outputs whenever the register is written.

0	RESERVED	R/W	0h	

30.5.3.3 PRU_ICSS_INTC_GER Register (offset = 10h) [reset = 0h]

PRU_ICSS_INTC_GER is shown in Figure 30-138 and described in Table 30-128.

The Global Host Interrupt Enable Register enables all the host interrupts. Individual host interrupts are still enabled or disabled from their individual enables and are not overridden by the global enable.

31-1	RESERVED	R/W	0h	
0	EN_HINT_ANY	R/W	0h	The current global enable value when read. Writes set the global enable.

30.5.3.4 PRU_ICSS_INTC_GNLR Register (offset = 1Ch) [reset = 100h]

PRU_ICSS_INTC_GNLR is shown in Figure 30-139 and described in Table 30-129.

The Global Nesting Level Register allows the checking and setting of the global nesting level across all host interrupts when automatic global nesting mode is set. The nesting level is the channel (and all of lower priority) that are nested out because of a current interrupt. This register is only available when nesting is configured.

Figure 30-139. PRU_ICSS_INTC_GNLR Register

Bit	Field	Type	Reset	Description
31	AUTO_OVERRIDE	W	0h	Always read as 0. Writes of 1 override the automatic nesting and set the nesting_level to the written data.
30-9	RESERVED	R/W	0h	
8-0	GLB_NEST_LEVEL	R/W	100h	The current global nesting level (highest channel that is nested). Writes set the nesting level. In auto nesting mode this value is updated internally unless the auto_override bit is set.

30.5.3.5 PRU_ICSS_INTC_SISR Register (offset = 20h) [reset = 0h]

PRU_ICSS_INTC_SISR is shown in Figure 30-140 and described in Table 30-130.

The System Event Status Indexed Set Register allows setting the status of an event. The event to set is the index value written (0-63). This sets the Raw Status Register bit of the given index.

Figure 30-140. PRU_ICSS_INTC_SISR Register

30.5.3.9 PRU_ICSS_INTC_HIEISR Register (offset = 34h) [reset = 0h]

PRU_ICSS_INTC_HIEISR is shown in Figure 30-144 and described in Table 30-134.

The Host Interrupt Enable Indexed Set Register allows enabling a host interrupt output. The host interrupt to enable is the index value written (0-9). This enables the host interrupt output or triggers the output again if already enabled.

30.5.3.52 PRU_ICSS_INTC_SITR1 Register (offset = D84h) [reset = 0h]

PRU_ICSS_INTC_SITR1 is shown in Figure 30-187 and described in Table 30-177.

The System Event Type Register1 define the type of the system events 32 to 63. There is a type for each system event. The type of all system events is pulse; always write 0 to the bits of this register.

Table 30-177. PRU_ICSS_INTC_SITR1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	TYPE_63_32	R/W	0h	Interrupt type of the system events 32 to 63. 0 = level or pulse interrupt. 1 = edge interrupt (required edge detect).

30.5.3.53 PRU_ICSS_INTC_HINLR0 Register (offset = 1100h) [reset = 100h]

PRU_ICSS_INTC_HINLR0 is shown in Figure 30-188 and described in Table 30-178.

The Host Interrupt Nesting Level Register0 display and control the nesting level for host interrupt 0. The nesting level controls which channel and lower priority channels are nested. There is one register per host interrupt.

8-0	NEST_HINT_0	R/W	100h	Reads return the current nesting level for the host interrupt. Writes set the nesting level for the host interrupt. In auto mode the value is updated internally unless the auto_override is set and then the write data is used.

30.5.3.54 PRU_ICSS_INTC_HINLR1 Register (offset = 1104h) [reset = 100h]

PRU_ICSS_INTC_HINLR1 is shown in Figure 30-189 and described in Table 30-179.

The Host Interrupt Nesting Level Register1 display and control the nesting level for host interrupt 1. The nesting level controls which channel and lower priority channels are nested. There is one register per host interrupt.

8-0	NEST_HINT_1	R/W	100h	Reads return the current nesting level for the host interrupt. Writes set the nesting level for the host interrupt. In auto mode the value is updated internally unless the auto_override is set and then the write data is used.

30.5.3.55 PRU_ICSS_INTC_HINLR2 Register (offset = 1108h) [reset = 100h]

PRU_ICSS_INTC_HINLR2 is shown in Figure 30-190 and described in Table 30-180.

The Host Interrupt Nesting Level Register2 display and control the nesting level for host interrupt 2. The nesting level controls which channel and lower priority channels are nested. There is one register per host interrupt.

30.5.3.63 PRU_ICSS_INTC_HIER Register (offset = 1500h) [reset = 0h]

PRU_ICSS_INTC_HIER is shown in Figure 30-198 and described in Table 30-188.

The Host Interrupt Enable Registers enable or disable individual host interrupts. These work separately from the global enables. There is one bit per host interrupt. These bits are updated when writing to the Host Interrupt Enable Index Set and Host Interrupt Enable Index Clear registers.

30.5.5 PRU_ICSS_UART Registers

The system programmer has access to and control over any of the UART registers that are listed in Table 30-249. These registers, which control UART operations, receive data, and transmit data, are available at 32-bit addresses in the device memory map.

- RBR, THR, and DLL share one address. When the DLAB bit in LCR is 0, reading from the address gives the content of RBR, and writing to the address modifies THR. When DLAB = 1, all accesses at the address read or modify DLL. DLL can also be accessed with address offset 20h.
- IER and DLH share one address. When DLAB = 0, all accesses read or modify IER. When DLAB = 1, all accesses read or modify DLH. DLH can also be accessed with address offset 24h.
- IIR and FCR share one address. Regardless of the value of the DLAB bit, reading from the address gives the content of IIR, and writing modifies FCR.

30.5.5.1 Receiver Buffer Register (RBR)

The receiver buffer register (RBR) is shown in Figure 30-258 and described in Table 30-250.

The UART receiver section consists of a receiver shift register (RSR) and a receiver buffer register (RBR). When the UART is in the FIFO mode, RBR is a 16-byte FIFO. Timing is supplied by the 16x receiver clock or 13x receiver clock by programming OSM_SEL bit field of MDR register. Receiver section control is a function of the line control register (LCR).

RSR receives serial data from the UARTn_RXD pin. Then RSR concatenates the data and moves it into RBR (or the receiver FIFO). In the non-FIFO mode, when a character is placed in RBR and the receiver data-ready interrupt is enabled (DR = 1 in IER), an interrupt is generated. This interrupt is cleared when the character is read from RBR. In the FIFO mode, the interrupt is generated when the FIFO is filled to the trigger level selected in the FIFO control register (FCR), and it is cleared when the FIFO contents drop below the trigger level.

Access considerations:

RBR, THR, and DLL share one address. To read RBR, write 0 to the DLAB bit in LCR, and read from the shared address. When DLAB = 0, writing to the shared address modifies THR. When DLAB = 1, all accesses at the shared address read or modify DLL.

DLL also has a dedicated address. If you use the dedicated address, you can keep DLAB = 0, so that RBR and THR are always selected at the shared address.

30.5.5.2 Transmitter Holding Register (THR)

The transmitter holding register (THR) is shown in Figure 30-259 and described in Table 30-251.

The UART transmitter section consists of a transmitter hold register (THR) and a transmitter shift register (TSR). When the UART is in the FIFO mode, THR is a 16-byte FIFO. Transmitter section control is a function of the line control register (LCR).

THR receives data from the internal data bus and when TSR is idle, the UART moves the data from THR to TSR. The UART serializes the data in TSR and transmits the data on the TX pin. In the non-FIFO mode, if THR is empty and the THR empty (THRE) interrupt is enabled (ETBEI = 1 in IER), an interrupt is generated. This interrupt is cleared when a character is loaded into THR or the interrupt identification register (IIR) is read. In the FIFO mode, the interrupt is generated when the transmitter FIFO is empty, and it is cleared when at least one byte is loaded into the FIFO or IIR is read.

Access considerations:

RBR, THR, and DLL share one address. To load THR, write 0 to the DLAB bit of LCR, and write to the shared address. When DLAB = 0, reading from the shared address gives the content of RBR. When DLAB = 1, all accesses at the address read or modify DLL.

DLL also has a dedicated address. If you use the dedicated address, you can keep DLAB = 0, so that RBR and THR are always selected at the shared address.

7-0	DATA	0-FFh	Data to transmit

30.5.5.3 Interrupt Enable Register (IER)

The interrupt enable register (IER) is used to individually enable or disable each type of interrupt request that can be generated by the UART. Each interrupt request that is enabled in IER is forwarded to the CPU. IER is shown in Figure 30-260 and described in Table 30-252.

Access considerations:

IER and DLH share one address. To read or modify IER, write 0 to the DLAB bit in LCR. When DLAB = 1, all accesses at the shared address read or modify DLH.

DLH also has a dedicated address. If you use the dedicated address, you can keep DLAB = 0, so that IER is always selected at the shared address.

Bit	Field	Value	Description
31-4	Reserved	0	Reserved
3	EDSSI	0	Enable Modem Status Interrupt
2	ELSI		Receiver line status interrupt enable.
		0	Receiver line status interrupt is disabled.
		1	Receiver line status interrupt is enabled.
1	ETBEI		Transmitter holding register empty interrupt enable.
		0	Transmitter holding register empty interrupt is disabled.
		1	Transmitter holding register empty interrupt is enabled.
0	ERBI		Receiver data available interrupt and character timeout indication interrupt enable.
		0	Receiver data available interrupt and character timeout indication interrupt is disabled.
		1	Receiver data available interrupt and character timeout indication interrupt is enabled.

30.5.5.4 Interrupt Identification Register (IIR)

The interrupt identification register (IIR) is a read-only register at the same address as the FIFO control register (FCR), which is a write-only register. When an interrupt is generated and enabled in the interrupt enable register (IER), IIR indicates that an interrupt is pending in the IPEND bit and encodes the type of interrupt in the INTID bits. Reading IIR clears any THR empty (THRE) interrupts that are pending.

IIR is shown in Figure 30-261 and described in Figure 30-261.

The UART has an on-chip interrupt generation and prioritization capability that permits flexible communication with the CPU. The UART provides three priority levels of interrupts:

- Priority 1 - Receiver line status (highest priority)
- Priority 2 - Receiver data ready or receiver timeout
- Priority 3 - Transmitter holding register empty

The FIFOEN bit in IIR can be checked to determine whether the UART is in the FIFO mode or the non-FIFO mode.

Access consideration:

IIR and FCR share one address. Regardless of the value of the DLAB bit in LCR, reading from the address gives the content of IIR, and writing to the address modifies FCR.

Table 30-253. Interrupt Identification Register (IIR) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-6	FIFOEN	0-3h	FIFOs enabled.
		0	Non-FIFO mode
		1h-2h	Reserved
		3h	FIFOs are enabled. FIFOEN bit in the FIFO control register (FCR) is set to 1.
5-4	Reserved	0	Reserved
3-1	INTID	0-7h	Interrupt type. See Table 30-254.
		0	Reserved
		1h	Transmitter holding register empty (priority 3)
		2h	Receiver data available (priority 2)
		3h	Receiver line status (priority 1, highest)
		4h-5h	Reserved
		6h	Character timeout indication (priority 2)
		7h	Reserved
0	IPEND		Interrupt pending. When any UART interrupt is generated and is enabled in IER, IPEND is forced to 0. IPEND remains 0 until all pending interrupts are cleared or until a hardware reset occurs. If no interrupts are enabled, IPEND is never forced to 0.
		0	Interrupts pending.
		1	No interrupts pending.

Table 30-254. Interrupt Identification and Interrupt Clearing Information

Priority Level	IIR Bits				Interrupt Type	Interrupt Source	Event That Clears Interrupt
	3	2	1	0			
None	0	0	0	1	None	None	None
1	0	1	1	0	Receiver line status	Overrun error, parity error, framing error, or break is detected.	For an overrun error, reading the line status register (LSR) clears the interrupt. For a parity error, framing error, or break, the interrupt is cleared only after all the erroneous data have been read.
2	0	1	0	0	Receiver data-ready	Non-FIFO mode: Receiver data is ready.	Non-FIFO mode: The receiver buffer register (RBR) is read.
						FIFO mode: Trigger level reached. If four character times (see Table 30-36) pass with no access of the FIFO, the interrupt is asserted again.	FIFO mode: The FIFO drops below the trigger level.[1]
2	1	1	0	0	Receiver time-out	FIFO mode only: No characters have been removed from or input to the receiver FIFO during the last four character times (see Table 30-36), and there is at least one character in the receiver FIFO during this time.	One of the following events: • A character is read from the receiver FIFO.[1] • A new character arrives in the receiver FIFO. • The URRST bit in the power and emulation management register (PWREMU_MGMT) is loaded with 0.
3	0	0	1	0	Transmitter holding register empty	Non-FIFO mode: Transmitter holding register (THR) is empty. FIFO mode: Transmitter FIFO is empty.	A character is written to the transmitter holding register (THR) or the interrupt identification register (IIR) is read.

[1] In the FIFO mode, the receiver data-ready interrupt or receiver time-out interrupt is cleared by the CPU or by the DMA controller, whichever reads from the receiver FIFO first.

30.5.5.5 FIFO Control Register (FCR)

The FIFO control register (FCR) is a write-only register at the same address as the interrupt identification register (IIR), which is a read-only register. Use FCR to enable and clear the FIFOs and to select the receiver FIFO trigger level FCR is shown in Figure 30-262 and described in Table 30-255. The FIFOEN bit must be set to 1 before other FCR bits are written to or the FCR bits are not programmed.

Access consideration:

IIR and FCR share one address. Regardless of the value of the DLAB bit, reading from the address gives the content of IIR, and writing to the address modifies FCR.

> **CAUTION**
>
> For proper communication between the UART and the EDMA controller, the DMAMODE1 bit must be set to 1. Always write a 1 to the DMAMODE1 bit, and after a hardware reset, change the DMAMODE1 bit from 0 to 1.

LEGEND: R = Read only; W = Write only; W1C = Write 1 to clear (writing 0 has no effect); -*n* = value after reset

[1] Always write 1 to the DMAMODE1 bit. After a hardware reset, change the DMAMODE1 bit from 0 to 1. DMAMODE = 1 is required for proper communication between the UART and the DMA controller.

Table 30-255. FIFO Control Register (FCR) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7-6	RXFIFTL	0-3h	Receiver FIFO trigger level. RXFIFTL sets the trigger level for the receiver FIFO. When the trigger level is reached, a receiver data-ready interrupt is generated (if the interrupt request is enabled). Once the FIFO drops below the trigger level, the interrupt is cleared.
		0	1 byte
		1h	4 bytes
		2h	8 bytes
		3h	14 bytes
5-4	Reserved	0	Reserved
3	DMAMODE1		DMA MODE1 enable if FIFOs are enabled. Always write 1 to DMAMODE1. After a hardware reset, change DMAMODE1 from 0 to 1. DMAMOD1 = 1 is a requirement for proper communication between the UART and the EDMA controller.
		0	DMA MODE1 is disabled.
		1	DMA MODE1 is enabled.
2	TXCLR		Transmitter FIFO clear. Write a 1 to TXCLR to clear the bit.
		0	No effect.
		1	Clears transmitter FIFO and resets the transmitter FIFO counter. The shift register is not cleared.
1	RXCLR		Receiver FIFO clear. Write a 1 to RXCLR to clear the bit.
		0	No effect.
		1	Clears receiver FIFO and resets the receiver FIFO counter. The shift register is not cleared.
0	FIFOEN		Transmitter and receiver FIFOs mode enable. FIFOEN must be set before other FCR bits are written to or the FCR bits are not programmed. Clearing this bit clears the FIFO counters.
		0	Non-FIFO mode. The transmitter and receiver FIFOs are disabled, and the FIFO pointers are cleared.
		1	FIFO mode. The transmitter and receiver FIFOs are enabled.

30.5.5.6 Line Control Register (LCR)

The line control register (LCR) is shown in Figure 30-263 and described in Table 30-256.

The system programmer controls the format of the asynchronous data communication exchange by using LCR. In addition, the programmer can retrieve, inspect, and modify the content of LCR; this eliminates the need for separate storage of the line characteristics in system memory.

Figure 30-263. Line Control Register (LCR)

Table 30-256. Line Control Register (LCR) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	DLAB		Divisor latch access bit. The divisor latch registers (DLL and DLH) can be accessed at dedicated addresses or at addresses shared by RBR, THR, and IER. Using the shared addresses requires toggling DLAB to change which registers are selected. If you use the dedicated addresses, you can keep DLAB = 0.
		0	Allows access to the receiver buffer register (RBR), the transmitter holding register (THR), and the interrupt enable register (IER) selected. At the address shared by RBR, THR, and DLL, the CPU can read from RBR and write to THR. At the address shared by IER and DLH, the CPU can read from and write to IER.
		1	Allows access to the divisor latches of the baud generator during a read or write operation (DLL and DLH). At the address shared by RBR, THR, and DLL, the CPU can read from and write to DLL. At the address shared by IER and DLH, the CPU can read from and write to DLH.
6	BC		Break control.
		0	Break condition is disabled.
		1	Break condition is transmitted to the receiving UART. A break condition is a condition where the UARTn_TXD signal is forced to the spacing (cleared) state.
5	SP		Stick parity. The SP bit works in conjunction with the EPS and PEN bits. The relationship between the SP, EPS, and PEN bits is summarized in Table 30-257.
		0	Stick parity is disabled.
		1	Stick parity is enabled. • When odd parity is selected (EPS = 0), the PARITY bit is transmitted and checked as set. • When even parity is selected (EPS = 1), the PARITY bit is transmitted and checked as cleared.
4	EPS		Even parity select. Selects the parity when parity is enabled (PEN = 1). The EPS bit works in conjunction with the SP and PEN bits. The relationship between the SP, EPS, and PEN bits is summarized in Table 30-257.
		0	Odd parity is selected (an odd number of logic 1s is transmitted or checked in the data and PARITY bits).
		1	Even parity is selected (an even number of logic 1s is transmitted or checked in the data and PARITY bits).
3	PEN		Parity enable. The PEN bit works in conjunction with the SP and EPS bits. The relationship between the SP, EPS, and PEN bits is summarized in Table 30-257.
		0	No PARITY bit is transmitted or checked.
		1	Parity bit is generated in transmitted data and is checked in received data between the last data word bit and the first STOP bit.

Table 30-256. Line Control Register (LCR) Field Descriptions (continued)

Bit	Field	Value	Description
2	STB		Number of STOP bits generated. STB specifies 1, 1.5, or 2 STOP bits in each transmitted character. When STB = 1, the WLS bit determines the number of STOP bits. The receiver clocks only the first STOP bit, regardless of the number of STOP bits selected. The number of STOP bits generated is summarized in Table 30-258.
		0	1 STOP bit is generated.
		1	WLS bit determines the number of STOP bits: • When WLS = 0, 1.5 STOP bits are generated. • When WLS = 1h, 2h, or 3h, 2 STOP bits are generated.
1-0	WLS	0-3h	Word length select. Number of bits in each transmitted or received serial character. When STB = 1, the WLS bit determines the number of STOP bits.
		0	5 bits
		1h	6 bits
		2h	7 bits
		3h	8 bits

Table 30-257. Relationship Between ST, EPS, and PEN Bits in LCR

ST Bit	EPS Bit	PEN Bit	Parity Option
x	x	0	Parity disabled: No PARITY bit is transmitted or checked
0	0	1	Odd parity selected: Odd number of logic 1s
0	1	1	Even parity selected: Even number of logic 1s
1	0	1	Stick parity selected with PARITY bit transmitted and checked as set
1	1	1	Stick parity selected with PARITY bit transmitted and checked as cleared

Table 30-258. Number of STOP Bits Generated

STB Bit	WLS Bits	Word Length Selected with WLS Bits	Number of STOP Bits Generated	Baud Clock (BCLK) Cycles
0	x	Any word length	1	16
1	0h	5 bits	1.5	24
1	1h	6 bits	2	32
1	2h	7 bits	2	32
1	3h	8 bits	2	32

30.5.5.7 Modem Control Register (MCR)

The modem control register (MCR) is shown in Figure 30-264 and described in Table 30-259. The modem control register provides the ability to enable/disable the autoflow functions, and enable/disable the loopback function for diagnostic purposes.

Figure 30-264. Modem Control Register (MCR)

31	16
Reserved	
R-0	

15	6	5	4	3	2	1	0
Reserved		AFE[1]	LOOP	OUT2	OUT1	RTS[1]	Rsvd
R-0		R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R-0

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

[1] All UARTs do not support this feature, see your device-specific data manual for supported features. If this feature is not available, this bit is reserved and should be cleared to 0.

Table 30-259. Modem Control Register (MCR) Field Descriptions

Bit	Field	Value	Description
31-6	Reserved	0	Reserved
5	AFE		Autoflow control enable. Autoflow control allows the $\overline{\text{UARTn\_RTS}}$ and $\overline{\text{UARTn\_CTS}}$ signals to provide handshaking between UARTs during data transfer. When AFE = 1, the RTS bit determines the autoflow control enabled. Note that all UARTs do not support this feature, see your device-specific data manual for supported features. If this feature is not available, this bit is reserved and should be cleared to 0.
		0	Autoflow control is disabled.
		1	Autoflow control is enabled: • When RTS = 0, $\overline{\text{UARTn\_CTS}}$ is only enabled. • When RTS = 1, $\overline{\text{UARTn\_RTS}}$ and $\overline{\text{UARTn\_CTS}}$ are enabled.
4	LOOP		Loop back mode enable. LOOP is used for the diagnostic testing using the loop back feature.
		0	Loop back mode is disabled.
		1	Loop back mode is enabled. When LOOP is set, the following occur: • The UARTn_TXD signal is set high. • The UARTn_RXD pin is disconnected • The output of the transmitter shift register (TSR) is lopped back in to the receiver shift register (RSR) input.
3	OUT2	0	OUT2 Control Bit
2	OUT1	0	OUT1 Control Bit
1	RTS		RTS control. When AFE = 1, the RTS bit determines the autoflow control enabled. Note that all UARTs do not support this feature, see your device-specific data manual for supported features. If this feature is not available, this bit is reserved and should be cleared to 0.
		0	$\overline{\text{UARTn\_RTS}}$ is disabled, $\overline{\text{UARTn\_CTS}}$ is only enabled.
		1	$\overline{\text{UARTn\_RTS}}$ and $\overline{\text{UARTn\_CTS}}$ are enabled.
0	Reserved	0	Reserved

30.5.5.8 Line Status Register (LSR)

The line status register (LSR) is shown in Figure 30-265 and described in Table 30-260. LSR provides information to the CPU concerning the status of data transfers. LSR is intended for read operations only; do not write to this register. Bits 1 through 4 record the error conditions that produce a receiver line status interrupt.

Figure 30-265. Line Status Register (LSR)

31–16

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	RXFIFOE		Receiver FIFO error.
			In non-FIFO mode:
		0	There has been no error, or RXFIFOE was cleared because the CPU read the erroneous character from the receiver buffer register (RBR).
		1	There is a parity error, framing error, or break indicator in the receiver buffer register (RBR).
			In FIFO mode:
		0	There has been no error, or RXFIFOE was cleared because the CPU read the erroneous character from the receiver FIFO and there are no more errors in the receiver FIFO.
		1	At least one parity error, framing error, or break indicator in the receiver FIFO.
6	TEMT		Transmitter empty (TEMT) indicator.
			In non-FIFO mode:
		0	Either the transmitter holding register (THR) or the transmitter shift register (TSR) contains a data character.
		1	Both the transmitter holding register (THR) and the transmitter shift register (TSR) are empty.
			In FIFO mode:
		0	Either the transmitter FIFO or the transmitter shift register (TSR) contains a data character.
		1	Both the transmitter FIFO and the transmitter shift register (TSR) are empty.
5	THRE		Transmitter holding register empty (THRE) indicator. If the THRE bit is set and the corresponding interrupt enable bit is set (ETBEI = 1 in IER), an interrupt request is generated.
			In non-FIFO mode:
		0	Transmitter holding register (THR) is not empty. THR has been loaded by the CPU.
		1	Transmitter holding register (THR) is empty (ready to accept a new character). The content of THR has been transferred to the transmitter shift register (TSR).
			In FIFO mode:
		0	Transmitter FIFO is not empty. At least one character has been written to the transmitter FIFO. You can write to the transmitter FIFO if it is not full.
		1	Transmitter FIFO is empty. The last character in the FIFO has been transferred to the transmitter shift register (TSR).

Table 30-260. Line Status Register (LSR) Field Descriptions (continued)

Bit	Field	Value	Description
4	BI		Break indicator. The BI bit is set whenever the receive data input (UARTn_RXD) was held low for longer than a full-word transmission time. A full-word transmission time is defined as the total time to transmit the START, data, PARITY, and STOP bits. If the BI bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in IER), an interrupt request is generated.
			In non-FIFO mode:
		0	No break has been detected, or the BI bit was cleared because the CPU read the erroneous character from the receiver buffer register (RBR).
		1	A break has been detected with the character in the receiver buffer register (RBR).
			In FIFO mode:
		0	No break has been detected, or the BI bit was cleared because the CPU read the erroneous character from the receiver FIFO and the next character to be read from the FIFO has no break indicator.
		1	A break has been detected with the character at the top of the receiver FIFO.
3	FE		Framing error (FE) indicator. A framing error occurs when the received character does not have a valid STOP bit. In response to a framing error, the UART sets the FE bit and waits until the signal on the RX pin goes high. Once the RX signal goes high, the receiver is ready to detect a new START bit and receive new data. If the FE bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in IER), an interrupt request is generated.
			In non-FIFO mode:
		0	No framing error has been detected, or the FE bit was cleared because the CPU read the erroneous data from the receiver buffer register (RBR).
		1	A framing error has been detected with the character in the receiver buffer register (RBR).
			In FIFO mode:
		0	No framing error has been detected, or the FE bit was cleared because the CPU read the erroneous data from the receiver FIFO and the next character to be read from the FIFO has no framing error.
		1	A framing error has been detected with the character at the top of the receiver FIFO.
2	PE		Parity error (PE) indicator. A parity error occurs when the parity of the received character does not match the parity selected with the EPS bit in the line control register (LCR). If the PE bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in IER), an interrupt request is generated.
			In non-FIFO mode:
		0	No parity error has been detected, or the PE bit was cleared because the CPU read the erroneous data from the receiver buffer register (RBR).
		1	A parity error has been detected with the character in the receiver buffer register (RBR).
			In FIFO mode:
		0	No parity error has been detected, or the PE bit was cleared because the CPU read the erroneous data from the receiver FIFO and the next character to be read from the FIFO has no parity error.
		1	A parity error has been detected with the character at the top of the receiver FIFO.
1	OE		Overrun error (OE) indicator. An overrun error in the non-FIFO mode is different from an overrun error in the FIFO mode. If the OE bit is set and the corresponding interrupt enable bit is set (ELSI = 1 in IER), an interrupt request is generated.
			In non-FIFO mode:
		0	No overrun error has been detected, or the OE bit was cleared because the CPU read the content of the line status register (LSR).
		1	Overrun error has been detected. Before the character in the receiver buffer register (RBR) could be read, it was overwritten by the next character arriving in RBR.
			In FIFO mode:
		0	No overrun error has been detected, or the OE bit was cleared because the CPU read the content of the line status register (LSR).
		1	Overrun error has been detected. If data continues to fill the FIFO beyond the trigger level, an overrun error occurs only after the FIFO is full and the next character has been completely received in the shift register. An overrun error is indicated to the CPU as soon as it happens. The new character overwrites the character in the shift register, but it is not transferred to the FIFO.

Table 30-260. Line Status Register (LSR) Field Descriptions (continued)

Bit	Field	Value	Description
0	DR		Data-ready (DR) indicator for the receiver. If the DR bit is set and the corresponding interrupt enable bit is set (ERBI = 1 in IER), an interrupt request is generated.
			In non-FIFO mode:
		0	Data is not ready, or the DR bit was cleared because the character was read from the receiver buffer register (RBR).
		1	Data is ready. A complete incoming character has been received and transferred into the receiver buffer register (RBR).
			In FIFO mode:
		0	Data is not ready, or the DR bit was cleared because all of the characters in the receiver FIFO have been read.
		1	Data is ready. There is at least one unread character in the receiver FIFO. If the FIFO is empty, the DR bit is set as soon as a complete incoming character has been received and transferred into the FIFO. The DR bit remains set until the FIFO is empty again.

30.5.5.9 Modem Status Register (MSR)

The Modem status register (MSR) is shown in Figure 30-266 and described in Table 30-261. MSR provides information to the CPU concerning the status of modem control signals. MSR is intended for read operations only; do not write to this register.

Figure 30-266. Modem Status Register (MSR)

31–16

Table 30-261. Modem Status Register (MSR) Field Descriptions

Bit	Field	Value	Description
31-8	Reserved	0	Reserved
7	CD	0	Complement of the Carrier Detect input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 3 (OUT2).
6	RI	0	Complement of the Ring Indicator input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 2 (OUT1).
5	DSR	0	Complement of the Data Set Ready input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 0 (DTR).
4	CTS	0	Complement of the Clear To Send input. When the UART is in the diagnostic test mode (loopback mode MCR[4] = 1), this bit is equal to the MCR bit 1 (RTS).
3	DCD	0	Change in DCD indicator bit. DCD indicates that the DCD input has changed state since the last time it was read by the CPU. When DCD is set and the modem status interrupt is enabled, a modem status interrupt is generated.
2	TERI	0	Trailing edge of RI (TERI) indicator bit. TERI indicates that the RI input has changed from a low to a high. When TERI is set and the modem status interrupt is enabled, a modem status interrupt is generated.
1	DDSR	0	Change in DSR indicator bit. DDSR indicates that the DSR input has changed state since the last time it was read by the CPU. When DDSR is set and the modem status interrupt is enabled, a modem status interrupt is generated.
0	DCTS	0	Change in CTS indicator bit. DCTS indicates that the CTS input has changed state since the last time it was read by the CPU. When DCTS is set (autoflow control is not enabled and the modem status interrupt is enabled), a modem status interrupt is generated. When autoflow control is enabled, no interrupt is generated.

30.5.5.10 Scratch Pad Register (SCR)

The Scratch Pad register (SCR) is shown in Figure 30-267 and described in Table 30-262. SCR is intended for programmer's use as a scratch pad. It temporarily holds the programmer's data without affecting UART operation.

31-8	Reserved	0	Reserved
7-0	SCR	0	These bits are intended for the programmer's use as a scratch pad in the sense that it temporarily holds the programmer's data without affecting any other UART operation.

30.5.5.11 Divisor Latches (DLL and DLH)

Two 8-bit register fields (DLL and DLH), called divisor latches, store the 16-bit divisor for generation of the baud clock in the baud generator. The latches are in DLH and DLL. DLH holds the most-significant bits of the divisor, and DLL holds the least-significant bits of the divisor. These divisor latches must be loaded during initialization of the UART in order to ensure desired operation of the baud generator. Writing to the divisor latches results in two wait states being inserted during the write access while the baud generator is loaded with the new value.

Access considerations:

- RBR, THR, and DLL share one address. When DLAB = 1 in LCR, all accesses at the shared address are accesses to DLL. When DLAB = 0, reading from the shared address gives the content of RBR, and writing to the shared address modifies THR.
- IER and DLH share one address. When DLAB = 1 in LCR, accesses to the shared address read or modify to DLH. When DLAB = 0, all accesses at the shared address read or modify IER.

DLL and DLH also have dedicated addresses. If you use the dedicated addresses, you can keep the DLAB bit cleared, so that RBR, THR, and IER are always selected at the shared addresses.

The divisor LSB latch (DLL) is shown in Figure 30-268 and described in Table 30-263. The divisor MSB latch (DLH) is shown in Figure 30-269 and described in Table 30-264.

Bit	Field	Value	Description
31-16	Reserved	0	Reserved
15	Reserved	0	Reserved. This bit must always be written with a 0.
14	UTRST		UART transmitter reset. Resets and enables the transmitter.
		0	Transmitter is disabled and in reset state.
		1	Transmitter is enabled.
13	URRST		UART receiver reset. Resets and enables the receiver.
		0	Receiver is disabled and in reset state.
		1	Receiver is enabled.
12-1	Reserved	1	Reserved
0	FREE		Free-running enable mode bit. This bit determines the emulation mode functionality of the UART. When halted, the UART can handle register read/write requests, but does not generate any transmission/reception, interrupts or events.
		0	If a transmission is not in progress, the UART halts immediately. If a transmission is in progress, the UART halts after completion of the one-word transmission.
		1	Free-running mode is enabled; UART continues to run normally.

30.5.5.14 Mode Definition Register (MDR)

The Mode Definition register (MDR) determines the over-sampling mode for the UART. MDR is shown in Figure 30-273 and described in Table 30-268.

Table 30-272. TXCFG0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RESERVED	R	0h	
30-28	TX_CLK_DELAY	R/W	0h	In order to guarantee the MII_RT IO timing values published in the device data manual, the ocp_clk must be configured for 200MHz and TX_CLK_DELAY must be set to 6h.
27-26	RESERVED	R	0h	
25-16	TX_START_DELAY	R/W	2h	Defines the minimum time interval (delay) between receiving the RXDV for the current frame and the start of the transmit interface sending data to the MII interface. Delay value is in units of MII_RT clock cycles, which uses the ocp_clk (default is 200MHz, or 5ns). Default TX_START_DELAY value is 320ns, which is optimized for minimum latency at 16 bit processing. Counter is started with RX_DV signal going active. Transmit interface stops sending data when no more data is written into transmit interface by PRU along with TX_EOF marker bit set. If the TX FIFO has data when the delay expires, then TX will start sending data. But if the TX FIFO is empty, it will not start until the TX FIFO is not empty. It is possible to overflow the TX FIFO with the max delay setting when auto-forwarding is enabled since the time delay is larger than the amount of data it needs to store. As long as TX L1 FIFO overflows, software will need to issue a TX_RESET to reset the TX FIFO. The total delay is 64-byte times (size of TX FIFO), but you need to allow delays for synchronization. Do to this fact, the maximum delay should be 80ns less when auto forwarding is enabled. Therefore, 0x3F0 is the maximum in this configuration.
15-10	RESERVED	R	0h	

Table 30-272. TXCFG0 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	TX_AUTO_SEQUENCE	R/W	0h	Enables transmit auto-sequence. Note the transmit data source is determined by TX_MUX_SEL setting. 0x 0: Disable 0x 1: Enable, transmit state machine based on events on receiver path that is connected to the respective transmitter. Also, the masking logic is disabled and only the MII data is used.
8	TX_MUX_SEL	R/W	0h	Selects transmit data source. The default/reset setting for TX Port 0 is 1. This setting permits MII TX Port 0 to receive data from PRU1 and the MII TX Port 1 which is connected to PRU0 by default. 0x 0: Data from PRU0 (default for TXCFG1) 0x 1: Data from PRU1 (default for TXCFG0)
7-4	RESERVED	R	1h	
3	TX_BYTE_SWAP	R/W	0h	Defines the order of Byte0/1 placement for TX R30. This bit must be selected/updated when the port is disabled or there is no traffic. 0x 0: R30 [15:8] = Byte1{Nibble3,Nibble2} R30[7:0] = Byte0{Nibble1,Nibble0} R30 [31:24] = TX_MASK [15:8] R30 [23:16] = TX_MASK [7:0] 0x 1: R30 [15:8] = Byte0{Nibble1,Nibble0} R30[7:0] = Byte1{Nibble3,Nibble2} R30 [31:24] = TX_MASK [7:0] R30 [23:16] = TX_MASK [15:8] Nibble0 is the first nibble received.
2	TX_EN_MODE	R/W	0h	Enables transmit self clear on TX_EOF event. Note that iep.cmp[3] must be set before transmission will start for TX0, and iep_cmp[4] for TX1. This is a new dependency, in addition to TX L1 FIFO not empty and TX_START_DELAY expiration, to start transmission. 0x 0: Disable 0x 1: Enable, TX_ENABLE will be clear for a TX_EOF event by itself.
1	TX_AUTO_PREAMBLE	R/W	0h	Transmit data auto-preamble. 0x 0: PRU will provide full preamble 0x 1: TX FIFO will insert pre-amble automatically. Note that the TX FIFO does not get preloaded with the preamble until the first write occurs. This can cause the latency to be larger than the minimum latency.
0	TX_ENABLE	R/W	0h	Enables transmit traffic on TX PORT. If TX_EN_MODE is set, then TX_ENABLE will self clear during a TX_EOF event. Note Software can use this to pre-fill the TX FIFO and then start the TX frame during non-ECS operations. 0x 0: TX PORT is disabled/stopped immediately 0x 1: TX PORT is enabled and the frame will start once the IPG counter expired and TX Start Delay counter has expired

30.5.7.4 TXCFG1 Register (Offset = 14h) [reset = 00400000h]

30-28	TX_CLK_DELAY	R/W	0h	In order to guarantee the MII_RT IO timing values published in the device data manual, the ocp_clk must be configured for 200MHz and TX_CLK_DELAY must be set to 6h.
27-26	RESERVED	R	0h	
25-16	TX_START_DELAY	R/W	40h	Defines the minimum time interval (delay) between receiving the RXDV for the current frame and the start of the transmit interface sending data to the MII interface. Delay value is in units of MII_RT clock cycles, which uses the ocp_clk (default is 200MHz, or 5ns). Default TX_START_DELAY value is 320ns, which is optimized for minimum latency at 16 bit processing. Counter is started with RX_DV signal going active. Transmit interface stops sending data when no more data is written into transmit interface by PRU along with TX_EOF marker bit set. If the TX FIFO has data when the delay expires, then TX will start sending data. But if the TX FIFO is empty, it will not start until the TX FIFO is not empty. It is possible to overflow the TX FIFO with the max delay setting when auto-forwarding is enabled since the time delay is larger than the amount of data it needs to store. As long as TX L1 FIFO overflows, software will need to issue a TX_RESET to reset the TX FIFO. The total delay is 64-byte times (size of TX FIFO), but you need to allow delays for synchronization. Do to this fact, the maximum delay should be 80ns less when auto forwarding is enabled. Therefore, 0x3F0 is the maximum in this configuration.
15-10	RESERVED	R	0h	

Table 30-273. TXCFG1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	TX_AUTO_SEQUENCE	R/W	0h	Enables transmit auto-sequence. Note the transmit data source is determined by TX_MUX_SEL setting. 0x 0: Disable 0x 1: Enable, transmit state machine based on events on receiver path that is connected to the respective transmitter. Also, the masking logic is disabled and only the MII data is used.
8	TX_MUX_SEL	R/W	0h	Selects transmit data source. The default/reset setting for TX Port 0 is 1. This setting permits MII TX Port 0 to receive data from PRU1 and the MII TX Port 1 which is connected to PRU0 by default. 0x 0: Data from PRU0 (default for TXCFG1) 0x 1: Data from PRU1 (default for TXCFG0)
7-4	RESERVED	R	0h	
3	TX_BYTE_SWAP	R/W	0h	Defines the order of Byte0/1 placement for TX R30. This bit must be selected/updated when the port is disabled or there is no traffic. 0x 0: R30 [15:8] = Byte1{Nibble3,Nibble2} R30[7:0] = Byte0{Nibble1,Nibble0} R30 [31:24] = TX_MASK [15:8] R30 [23:16] = TX_MASK [7:0] 0x 1: R30 [15:8] = Byte0{Nibble1,Nibble0} R30[7:0] = Byte1{Nibble3,Nibble2} R30 [31:24] = TX_MASK [7:0] R30 [23:16] = TX_MASK [15:8] Nibble0 is the first nibble received.
2	TX_EN_MODE	R/W	0h	Enables transmit self clear on TX_EOF event. Note that iep.cmp[3] must be set before transmission will start for TX0, and iep_cmp[4] for TX1. This is a new dependency, in addition to TX L1 FIFO not empty and TX_START_DELAY expiration, to start transmission. 0x 0: Disable 0x 1: Enable, TX_ENABLE will be clear for a TX_EOF event by itself.
1	TX_AUTO_PREAMBLE	R/W	0h	Transmit data auto-preamble. 0x 0: PRU will provide full preamble 0x 1: TX FIFO will insert pre-amble automatically. Note that the TX FIFO does not get preloaded with the preamble until the first write occurs. This can cause the latency to be larger than the minimum latency.
0	TX_ENABLE	R/W	0h	Enables transmit traffic on TX PORT. If TX_EN_MODE is set, then TX_ENABLE will self clear during a TX_EOF event. Note Software can use this to pre-fill the TX FIFO and then start the TX frame during non-ECS operations. 0x 0: TX PORT is disabled/stopped immediately 0x 1: TX PORT is enabled and the frame will start once the IPG counter expired and TX Start Delay counter has expired

30.5.7.5 TXCRC0 Register (Offset = 20h) [reset = 0h]

TXCRC0 is shown in Figure 30-278 and described in Table 30-274.

Return to Summary Table.

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	X	
7-0	TX_FIFO_LEVEL	R	0h	Define the number of valid nibbles in the TX FIFO 0 = empty 1 = 1 Nibble 2 = 1 Byte/ 2 Nibble ... 128 = 64 Bytes/ 128 Nibbles

30.5.8 PRU_ICSS_MDIO Registers

For additional details about the MDIO registers, see *MDIO Registers* in the AM437x TRM (SPRUHL7).

30.5.9 PRU_ICSS_CFG Registers

Table 30-290 lists the memory-mapped registers for the PRU_ICSS_CFG. All register offset addresses not listed in Table 30-290 should be considered as reserved locations and the register contents should not be modified.

30.5.9.7 PRU_ICSS_CFG_ISP Register (Offset = 18h) [reset = 0h]

PRU_ICSS_CFG_ISP is shown in Figure 30-300 and described in Table 30-297.

Return to Summary Table.

The IRQ Status Parity Register is a snapshot of the IRQ status for the PRU ICSS memory parity events. The status is set only if the event is enabled. Write 1 to clear the status after the interrupt has been serviced.

Table 30-303. PRU_ICSS_CFG_SPP Register Field Descriptions

Bit	Field	Type	Reset	Description
31-2	RESERVED	R/W	0h	
1	XFR_SHIFT_EN	R/W	0h	Enables XIN/XOUT shift functionality. When enabled, R0 [4:0] (internal to PRU) defines the 32-bit offset for XIN and XOUT operations with the scratch pad. 0h (R/W) = Disabled 1h (R/W) = Enabled
0	PRU1_PAD_HP_EN	R/W	0h	Defines which PRU wins write cycle arbitration to a common scratch pad bank. The PRU which has higher priority will always perform the write cycle with no wait states. The lower PRU will get stalled/wait states until higher PRU is not performing write cycles. If the lower priority PRU writes to the same byte has the higher priority PRU, then the lower priority PRU will over write the bytes. 0h (R/W) = PRU0 has highest priority 1h (R/W) = PRU1 has highest priority

30.5.9.14 PRU_ICSS_CFG_PIN_MX Register (Offset = 40h) [reset = 0h]

PRU_ICSS_CFG_PIN_MX is shown in Figure 30-307 and described in Table 30-304.

Return to Summary Table.

The Pin Mux Select Register defines the state of the PRU ICSS internal pinmuxing.

Figure 30-307. PRU_ICSS_CFG_PIN_MX Register

Debug Subsystem

This chapter describes the debug subsystem of the device.

Topic **Page**

31.1 Chip Architecture Specification

31.1.1 Debug Resource Manager (DRM)

31.1.1.1 Debug Suspend Support for Peripherals

When a processor is halted, peripherals associated with the processor must appropriately respond to this event to avoid incorrect actions.

An example of this is the action of the Watchdog Timer (WDT) during a debug halt. Typically watchdog timers fire a reset to restart a system after a timeout. The reset could be misfired during debug if a processor is halted for a fairly long time and prevents a WDT monitor from refreshing the timer.

To prevent this incorrect action, the watchdog timer supports a debug suspend event. This event allows the WDT to stop counting during a CPU halt.

Other peripherals also support a debug suspend event. The list of supported peripherals is shown in Section 31.5.

Note that several peripherals have local control to gate the suspend event coming from the Debug Subsystem. For example, the WDT has an EMUFREE bit in the WDSC register to block the suspend event coming from the Debug Subsystem. Ensure this bit is set correctly to allow the suspend event to properly control the peripheral module.

Recommended Suspend Control Register Value:
  Normal mode: 0x0
  Suspend peripheral during debug halt: 0x9

31.1.2 On-Chip Debug and Trace

31.1.2.1 Introduction

Debugging a system containing an embedded processor involves an environment that connects high-level debugging software, executing on a host computer, to a low-level debug interface supported by the target device. In between these levels is a debug and trace controller (DTC) that facilitates communication between the host debugger and the debug support logic on the target chip.

A combination of hardware and software that connects the host debugger to the target system, the DTC uses one or more hardware interfaces and protocols to convert actions dictated by the debugger user to JTAG commands and scans that execute the core hardware. The debug software and hardware components let the user control multiple central processing unit (CPU) cores embedded in the device in a global or local manner. This environment provides:

- Synchronized global starting and stopping of multiple processors
- Starting and stopping of an individual processor
- Each processor can generate triggers than can be used to alter the execution flow of other processors.

System topics include but are not limited to:

- System clocking and power-down issues
- Interconnection of multiple devices
- Trigger channels

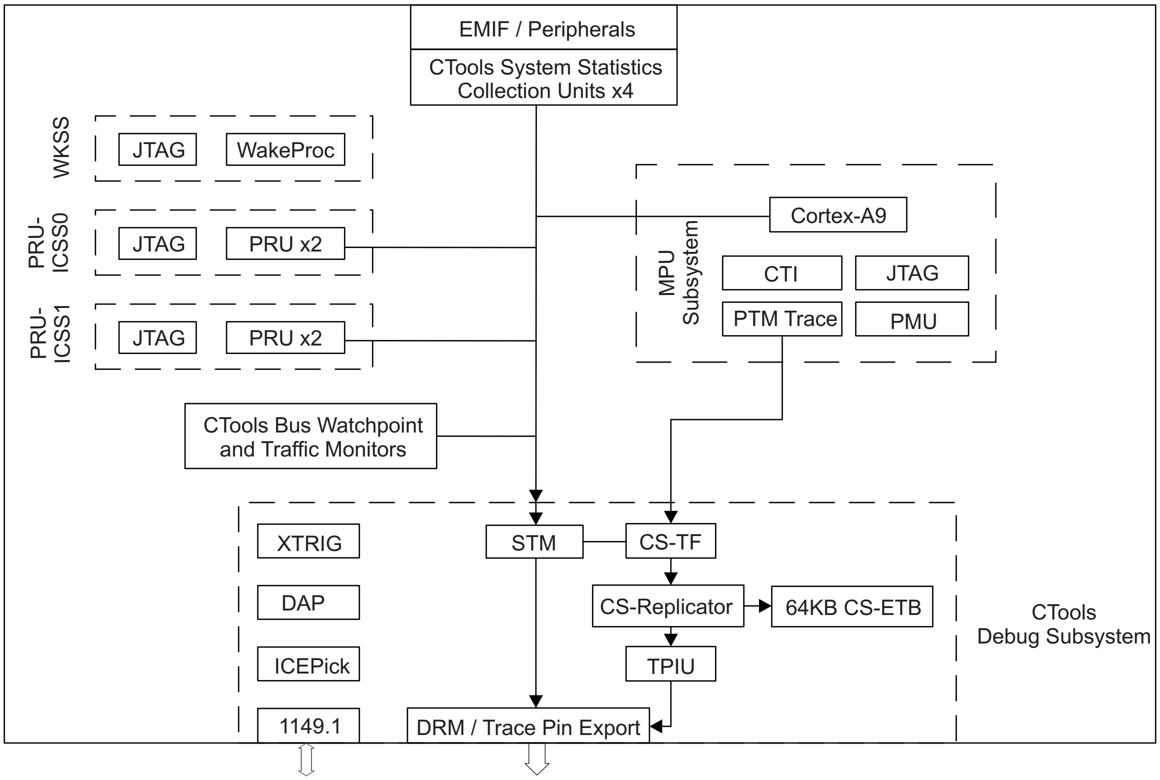
For easy integration into applications, a set of libraries (APIs) for debug-IP programming and a software message library are provided. More information about the APIs, download files, and other useful links for available libraries can be found on the CToolsLib Wiki site:

http://processors.wiki.ti.com/index.php/CToolsLib

CToolsLib is a collection of embedded target APIs and libraries that enable easy access to the chip tools (CTools), which are system-level debug facilities included in the debug subsystem of TI devices.

Figure 31-1 shows a high-level debug view of the functional block diagram.

Figure 31-1. Functional Block Diagram Debug View



31.1.2.1.1 Key Features

This device deploys the Texas Instruments CTools debug technology for on-chip debug and trace support.

CTools includes the following features:

- JTAG based single processor debugging on:
  - Cortex-A9 in MPU Subsystem
  - Wakeup Processor in Wakeup Subsystem
  - PRU x2 in PRU-ICSS1
  - PRU x2 in PRU-ICSS0
- Multiprocessor debugging lets users control multiple CPU cores embedded in the device, such as:
  - Global starting and stopping of individual or multiple processors
  - Each processor can generate triggers to alter the execution flow of other processors
  - System clocking and power down
  - Interconnection of multiple devices
  - Channel triggering
- Target debugging using the JTAG (IEEE1149.1) port
- Reduced power consumption in normal operating mode
- Real-time software trace allows software masters to transmit trace data from OS processes or tasks on 256 different channels

The debug subsystem includes:

- CTools Power Aware JTAG Router (ICEPick-D™)
- Debug access port (DAP)
- Processor trace subsystem
  - 64KB CoreSight Embedded Trace Buffer (CS-ETB)
- System trace subsystem
- EMU configuration interconnect
- Cross-triggering unit (XTRIGGER)
- Debug resource manager (DRM)
- CoreSight Trace Port Interface Unit (CS-TPIU)
- CORE instrumentation interconnect:
  - Initiator ports:
    - L3 interconnect for software instrumentation and performance probes
    - CTools System Bus Watchpoint and Traffic Monitors (OCP-WP)
  - Target port:
    - EMU instrumentation interconnect

CTools System Bus Watchpoint and Traffic Monitors (OCP-WP):

- Monitors L3 interconnect transaction when target transaction attributes match the user-defined attributes or trigger on external debug event
- Only one instance, shared among the following L3 targets:
  - GPMC
  - L4_FAST
  - L4_SLOW
  - L4_WAKEUP
  - EMIF
  - OCM_RAM

CTools System Statistics Collection Units (Statistics Collector): The L3 interconnect supports a built-in performance monitoring feature by implementing a statistics collector component, which computes traffic statistics within a user-defined window and periodically reports to the user through the MIPI-STM interface.

31.1.2.2 Debug Ports

31.1.2.2.1 IEEE 1149.1

The target debug interface has the following signals:

- Five standard IEEE1149.1 JTAG signals: nTRST, TCK, TMS, TDI, and TDO
- Two EMU [1:0] or five EMU [4:0] TI extensions, depending on the pin count (14 pins or 20 pins) in the JTAG header of the device.

Table 31-1 describes the IEEE1149.1 signals.

Table 31-1. IEEE 1149.1 Signals

Pin	Type	Name	Description
nTRST	I	Test Logic Reset	When asserted (active low) causes all test and debug logic in the device to be reset along with the IEEE 1149.1 interface
TCK	I	Test Clock	This is the test clock used to drive an IEEE 1149.1 TAP state machine and logic. Depending on the DTS attached to the device, this is a free running clock or a gated clock depending on RTCK monitoring.

Table 31-1. IEEE 1149.1 Signals (continued)

Pin	Type	Name	Description		
RTCK	O	Returned Test Clock	Synchronized TCK. Depending on the DTS attached to the device, the JTAG signals are clocked from RTCK or RTCK is monitored by the DTS to gate TCK.		
TMS	I	Test Mode Select	Directs the next state of the IEEE 1149.1 test access port state machine		
TDI	I	Test Data Input	Scan data input to the device		
TDO	O	Test Data Output	Scan data output of the device		
EMU0	I/O	Emulation 0	Channel 0 trigger	ICEPick Boot Mode	Trace port
EMU1	I/O	Emulation 1	Channel 1 trigger		
EMU2	O	Emulation 2	20-pins JTAG header only		
EMU3	O	Emulation 3			
EMU4	O	Emulation 4			

Table 31-2 describes the device's JTAG ID code, which is accessed through the ICEPick module embedded in the debug subsystem.

Table 31-2. JTAG ID Code

Device	JTAG ID
AM43xx	0000-1011-1001-1000-1100-0000-0010-1111
	0x0B98C02F

31.1.2.2.2 Trace Port

On-chip debug and trace events can be exported to external equipment through the trace port in the device. The following exportable debug events and trace sources are supported:

- Debug events:
  - Triggers. For more information about triggers, see Section 12.4.2, *Cross-Triggering*.
- Trace sources
  - Processor trace: Cortex-A9 MPU trace supported by CS_PTM module.
  - System trace: Trace coming from various system Instrumentation modules and supported by system trace module (STM). For more information about system trace, see Section 31.2, *System Instrumentation*.

Note that not all debug and trace features can be used simultaneously due to limited amount of pins allocated to debug. Thus, a multiplexing among debug and trace sources is implemented. The configuration and the selection of debug and trace sources is done through the debug resource manager (DRM) module embedded in the debug subsystem.

Table 31-3 describes the trace port signals.

Table 31-3. Trace Port Signals

Pin Name	Internal Signal Name	I/O	Description
dpm_emu11	EMU11	O	Debug Resource manager pin 11
dpm_emu10	EMU10	O	Debug Resource manager pin 10
dpm_emu9	EMU9	O	Debug Resource manager pin 9
dpm_emu8	EMU8	O	Debug Resource manager pin 8
dpm_emu7	EMU7	O	Debug Resource manager pin 7

Table 31-3. Trace Port Signals (continued)

Pin Name	Internal Signal Name	I/O	Description
dpm_emu6	EMU6	O	Debug Resource manager pin 6
dpm_emu5	EMU5	O	Debug Resource manager pin 5
dpm_emu4	EMU4	O	Debug Resource manager pin 4
dpm_emu3	EMU3	O	Debug Resource manager pin 3
dpm_emu2	EMU2	O	Debug Resource manager pin 2
dpm_emu1	EMU1	I/O	Debug Resource manager pin 1
dpm_emu0	EMU0	I/O	Debug Resource manager pin 0

NOTE: The dpm_emu[11:2] pins are shared with other functional (application) pins on the device boundary. To use the dpm_emu[4:2] pins, user must program the device application pin manager (control module) appropriately. For more information, see Chapter 7, *Control Module*.

31.1.2.2.3 Target Connection

TI supports a variety of eXtended Development System (XDS) JTAG controllers with various debug capabilities beyond only JTAG support. If your device supports the export of core trace or system trace over the EMU pins, and you want the target to be compatible with XDS products that are capable of acquiring either trace type, see the *Emulation and Trace Headers Technical Reference Manual* (SPRU655). You can also find more information at the “XDS Target Connection Guide” wiki page:

http://processors.wiki.ti.com/index.php/XDS_Target_Connection_Guide

31.1.3 Debugger Connection

31.1.3.1 ICEPick Module

The debugger connects to the device through its JTAG interface. The first level of debug interface seen by the debugger is connected to the ICEPick (version D) module that is embedded in the debug system.

System-on-chip (SoC) designs typically have multiple processors, each having a JTAG test access port (TAP) embedded in the processor. The ICEPick module manages these TAPs and the power, reset, and clock controls for modules that have TAPs.

ICEPick provides the following debug capabilities:

- Debug connect logic for enabling or disabling most ICEPick instructions
- Dynamic TAP insertion
  - Serially link up to 32 TAP controllers
  - Individually select one or more of the TAPS for scan without disrupting the instruction register (IR) state of other TAPs
- Power, reset and clock management
  - Provides the power and clock states of each domain
  - Provides debugger control of the processor power domain. Can force the domain power and clocks on, and prohibit the domain from being clock-gated or powered down while a debugger is connected.
  - Applies system reset

  - Provides wait-in-reset (WIR) boot mode
  - Provides global and local WIR release
  - Provides global and local reset block

The ICEPick module implements a connect register, which must be configured with a predefined key to enable the full set of JTAG instructions. Once the debug connect key is properly programmed, the emulation logics for the ICEPick signals and subsystems emulation logics should be turned on.

For more information about ICEPick dynamic TAP insertion, see Section 31.1.3.3, Dynamic TAP insertion.

For more information about ICEPick power, reset, and clock management features, see Section 31.1.6, *Power, Reset, and Clock Management Debug Support*.

31.1.3.2 Boot Modes

The initial configuration of ICEPick is determined by the level of the dpm_emu0 and dpm_emu1 pins upon POR release. At POR, dpm_emu0 and dpm_emu1 are automatically configured as inputs. The dpm_emu0 and dpm_emu1 pins are free once POR has been released.

Table 31-4 summarizes the ICEPick boot modes.

Table 31-4. ICEPick Boot Modes upon POR

dpm_emu1	dpm_emu0	TAPs in the TDI → TDO Path	Other Effects/Comments
0	0	None	Reserved (do not use)
0	1	None	Reserved (do not use)
1	0	ICEPick	TAP only + wait-in-reset mode
1	1	ICEPick	TAP only (default mode)

31.1.3.2.1 Default Boot Mode

In ICEPick-only configuration, none of the secondary TAPs are selected. The ICEPick TAP is the only TAP between device-level TDI and TDO pins. This is the recommended boot mode.

31.1.3.2.2 Wait-In-Reset (WIR)

The device can boot to invoke WIR mode. If the device is booted in WIR mode, all processors within the device that support a TAP through ICEPick are held in reset until released. Individual processors may be released from reset (local), or all processors held in the reset state may be released at the same time (global).

Note: The PRU processors in PRU-ICSS do not support WIR mode.

31.1.3.3 Dynamic TAP insertion

31.1.3.3.1 ICEPick Secondary TAPS

To include additional or fewer secondary TAPS in the scan chain, the debugger **must** use the ICEPick TAP router to program the TAPs. At its root, ICEPick is a scan-path linker that lets the DTC selectively choose which subsystem TAPs are accessible through the device-level debug interface. Each secondary TAP can be dynamically included in or excluded from the scan path. To the external JTAG interface, the secondary TAPs that are not selected appear not to exist.

Table 31-5 shows the secondary debug TAPs connect to the ICEPick scan chain along with the modules that can be accessed. The TAP number shows the position of the TAP in the scan chain.

Table 31-5. ICEPick Secondary Debug TAP Mapping

Secondary JTAG port	CoreSight	TAP	Modules Accessed through that JTAG Port

4	PRU1 in PRU-ICSS0
5-8	Reserved

31.1.4 Primary Debug Support

31.1.4.1 Processor Native Debug Support

31.1.4.1.1 Cortex-A9 MPU Subsystem

The Cortex-A9 processor supports the following native features:

- Halt mode and monitor mode debug
- Hardware breakpoints and watch points
- Performance monitoring

For more information about Cortex-A9 subsystem native debug support features, see the ARM Cortex-A9 Technical Reference Manual.

The PTM can send trace data to the ETB. The DAP handles all scan communications. The ARM Cortex-A9 core, the TI debug extender, the PTM, and the ETB are all accessible via memory-map transactions controlled by the DAP.

For details about the core, the PTM, and the ETB, see the ARM Limited documentation.

31.1.4.1.2 Wakeup Processor MPU

The wakeup processor supports the following native debug features:

- Program halt and stepping
- Hardware breakpoints, breakpoint instruction
- Data watch point on access to data add, add range, and data value
- Register value accesses
- Debug monitor exception
- Memory accesses

The Wake-up Subsystem includes one Cortex-M3 processor.

For more information about Cortex-M3 MPU native debug support features, see the ARM Cortex-M3 Technical Reference Manual.

31.1.4.1.3 PRU

The PRU processors in the PRU-ICSS1 and PRU-ICSS0 support the following native debug features:

- Manual halt
- Single-step execution
- Software Breakpoint

31.1.4.2 Cross Triggering

The device supports a cross-triggering feature, which propagates debug (trigger) events from one processor subsystem or module to another. For example, a given subsystem, A, can be programmed to generate a debug event, which can then be exported as a global trigger across the device. Another subsystem, B, can be programmed to be sensitive to the trigger line input and to generate an action upon trigger detection.

Examples of debug events include:

- Processor entering debug state
- Watch point match
- PTM trigger
- ETB full
- ETB acquisition complete

Examples of debug actions include:

- Debug request generation
- Restart (Cortex-A9 synchronous run)
- Interrupt request generation
- Start and stop trace

Subsystems cross-triggering is consolidated at the device level by the XTRIGGER module, which is embedded in the debug subsystem.

NOTE: XTRIGGER is not programmatically visible from the JTAG interface or any device processor. Cross-triggering is programmed at the subsystem level.

31.1.4.3 SOC Level Cross-Triggering

Table 31-7 summarizes the device cross-triggering capabilities.

Table 31-7. Cross-Triggering

	Trigger Source		MPU Cores	PTM/ ETB	PRU-ICSS1 PRU0	PRU-ICSS0 PRU1	PRU-ICSS0 PRU0	PRU-ICSS0 PRU1	Wakeup Processor	NOC_ SC	OCP_ WP	EMU0, EMU1
		Trigger Input	●	●	●	●	●	●	●	●	●	●
MPU	●	MPU Cores		●					●	●	●	●
	●	PTM / ETB	●							●	●	●
PRU-ICSS1	●	PRU0										
	●	PRU1										
PRU-ICSS0	●	PRU0										
	●	PRU1										
Wakeup	●	Wakeup Processor	●							●	●	●
SOC	-	NOC_ SC										
	●	OCP_ WP	●	●					●	●		●
	●	EMU0, EMU1	●	●					●	●	●	

The cross-trigger lines are shared by all the subsystems implementing cross-triggering. An MPU subsystem trigger event can, therefore, be propagated to any application subsystem or system trace component. The remote subsystem or system trace component can be programmed to be sensitive to the global SOC trigger lines for the following actions:

- Generate a processor debug request
- Generate an interrupt request
- Start processor trace
- Stop processor trace
- Start OCP target traffic monitoring
- Stop OCP target traffic monitoring
- Start NOC performance monitoring
- Stop NOC performance monitoring
- Start external logic analyzer trace
- Stop external logic analyzer trace

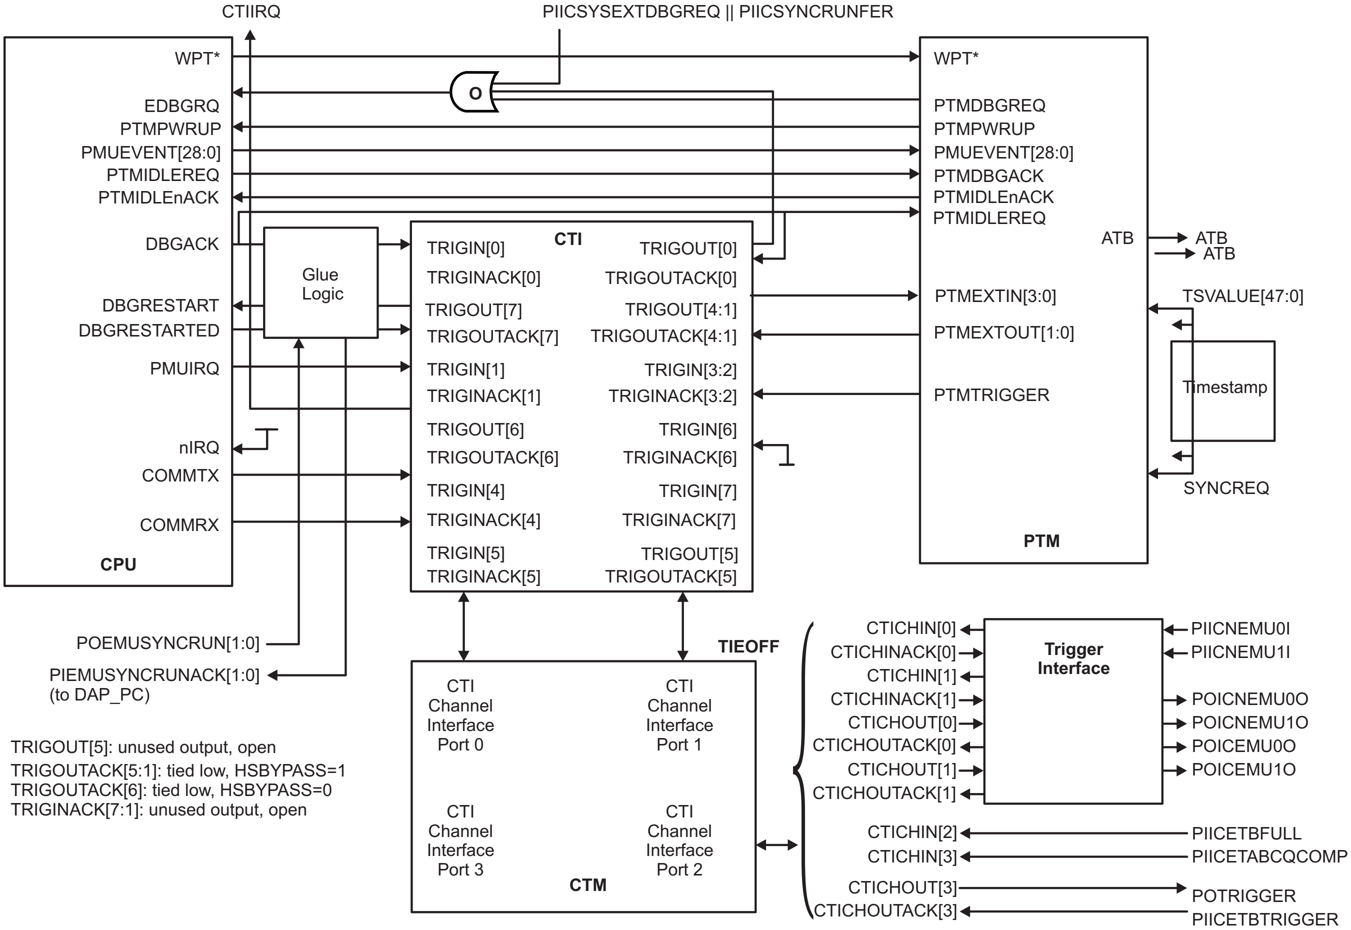
31.1.4.4 MPU Subsystem Cross-Triggering

The MPU subsystem (MPUSS) implements standard CoreSight components to perform SMP debug and emulation. There is one CTI and PTM module to handle cross-trigger and trace. The CTI is connected to a CTM (Cross Trigger Matrix) to enable cross trigger across CPUs. Since the MPUSS supports only one CPU, the other input of the CTM is tied-off. A trace funnel selects traces from the CPU and sends them to a single ATB interface. A time-stamp counter is included to enable correlation of trace stream from multiple processors.

Figure 31-2 shows the cross trigger connections of the MPUSS. The MPUSS does not include the ICECrusherCS. A trigger interface block is used to convert TI trigger format (EMU0/EMU1) to ARM CTI format.

The four ports of the CTM are connected to CTI0, CTI1 (tied-off), and the Trigger interface.

Figure 31-2. MPU Subsystem Cross Trigger Connections



TRIGOUT[5]: unused output, open
TRIGOUTACK[5:1]: tied low, HSBYPASS=1
TRIGOUTACK[6]: tied low, HSBYPASS=0
TRIGINACK[7:1]: unused output, open

31.1.5 Suspend

The device supports a suspend feature, which provides a way to stop a "closely-coupled" hardware process running on a peripheral-IP when the host processor enters debug state. The suspend mechanism is important for debug, because it ensures that peripheral-IPs operate in a lock-step manner with a host controller processor.

An entry is provided for each peripheral-IP that must consider the suspend signals from a number of processors (MPU or DSP). For each peripheral-IP, sensitivity to the suspend signals is defined within two possibilities (and so coded using 1bit):

- Peripheral-IP is sensitive to the suspend line request.
- Peripheral-IP ignores the suspend line request.

For more information about how to program the sensitivity, see the peripheral-IP chapter in this document.

31.1.5.1 Debug Aware Peripherals and Host Processors

Table 31-8 lists the mapping of the device peripheral-IPs to the suspend control output lines.

Table 31-8. Debug Subsystem Suspend Output Lines

Suspend Output Line	Peripheral-IP Module
0	System Watchdog Timer1
1	DM Timer0

26	Reserved
27	PWM3
28	PWM4
29	PWM5

NOTE: DM Timer7–11 are grouped together to share the same suspend output. Additional logic is needed at the SoC level to combine the suspend out for all the timers.

31.1.6 Power, Reset and Clock Management Debug Support

The global PRCM module implements facilities to support debug across power and clock domain cycles. The debugger can control or receive the status of each power and clock domain associated with an ICEPick secondary TAP.

ICEPick provides a set of directives that allow the debugger to:

- Access information on the associated power and clock domains state. This includes:
  - Current power setting indicating whether the power domain is on or off
  - Loss of power detected since the software last checked the power status
  - Current clock setting indicating whether the clock domain is on or off
  - Sleep desired (PM and CM indicate that the debug settings in ICEPick are changing the application state. If it were not for the ICEPick controls, the power or clock would be turned off.)
  - Subsystem reset state
  - Subsystem has entered a debug state that requires the attention of the host debug software
- Override power and clock control settings to wake up a power or clock domain or to prevent a power or clock domain from going to sleep once it is in ACTIVE state
- Assert, block, or extend reset and also release from extended reset (WIR)

ICEPick handles debug power management at the device level.

31.1.7 Performance Monitoring

31.1.7.1 Cortex-A9 MPU Subsystem Performance Monitoring

31.1.7.1.1 Performance Monitoring Unit

The Cortex-A9 processor includes a performance monitoring unit (PMU) that enables events, such as cache misses and instructions executed, to be counted over a period of time. The PMU gathers statistics about the operation of the processor and memory system.

For details of PMU events, please refer to the Cortex-A9 TRM.

31.1.8 Processor Trace

The device supports Cortex-A9 processor trace.

31.1.8.1 Cortex-A9 Processor Trace

The Cortex-A9 processor trace characteristics are:

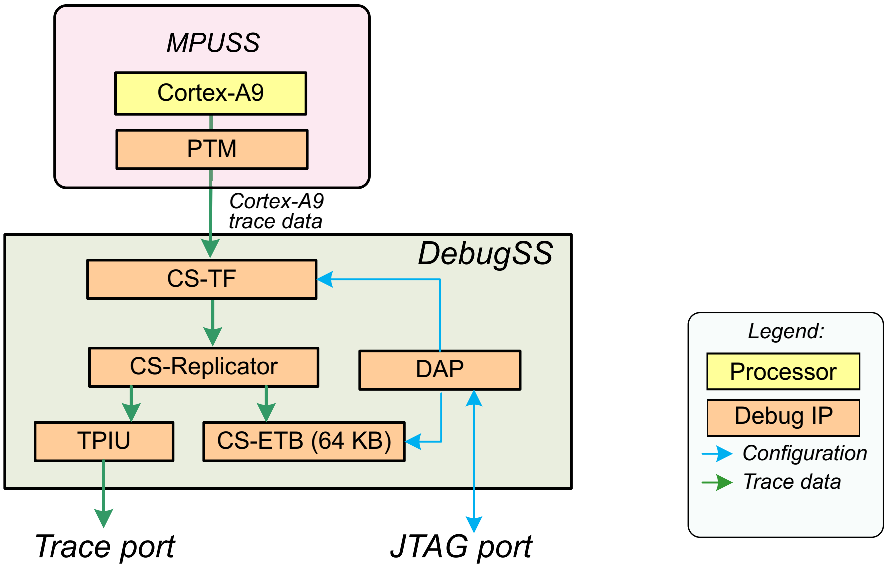
- Program trace
- Data trace (data address only, no data value)
- Trace can be stored on-chip to ETB or exported off chip via TPIU through CS-TF in the Debug Subsystem
- Optional: Trace can be cycle accurate (useful to profile sections of code)

For more details on the Cortex-A9 trace features, see the Cortex-A9 TRM.

31.1.8.2 SoC Processor Trace Flow

Figure 31-3 shows an overview of the SoC level processor trace flow for a Cortex-A9 trace.

Figure 31-3. SoC Processor Trace Flow



31.1.8.3 Trace Exported to an External Trace Receiver

31.1.8.3.1 Debug Resources Manager

Processor trace can be exported to an external trace receiver through the TPIU module. For this purpose, the debugger or application software must program the DRM module properly.

31.1.8.3.2 Trace Port Width Configuration

The TPIU has a software configurable export width of 10 or 12 data pins (TRACEDATA) plus a dedicated export clock (TRACECLK) and a control signal (TRACECTL).

31.1.8.3.3 Tuning Export Clock Frequency

The device implements two processor trace export clock (TRACECLK) generation schemes:

- Trace export clock generated from the Debug Subsystem Programmable Delay Line Oscillator (PDLO)
- Programmable DPLL reference clock shared with application with programmable post-dividers

---

NOTE:

1. Selection between PDLO and PMD schemes is done at the DRM level.
2. The debug subsystem also implements a dedicated PDLO module for STM.

31.1.8.3.4 Tuning Export Clock Frequency Through PDLO

The Debug Subsystem implements a dedicated PDLO module for Processor Trace export clock generation. The PDLO provides a wide operating frequency range to compensate for process, voltage and temperature variations. The PDLO also contains a post clock divider to further extend the operating frequency range.

The PDLO contains two identical delay lines with 32 x TAPs each. The delays lines are operated in ring oscillator mode. The PDLO output frequency will be programmed by the debug software by measuring the delay line output frequency, adjusting the delay TAP and post divider until the desired frequency is reached. After the delay lines are set to the correct operating frequency, the high and low limit registers are programmed with the maximum and minimum tolerances. The PDLO periodically monitors the output frequency, and if it detects the frequency is drifting out of tolerance, it initiates a calibration cycle (typically 3 to 79 times per second).

The calibration cycle will select the alternate delay line and measure its operating frequency. The delay tap select value is incremented or decremented, adjusting the frequency until it is within tolerance. Once the alternate delay line frequency is in tolerance, the controller will synchronously switch between the two delay lines. When the switch occurs, the export clock will stop for two clock cycles. During these two cycles, the processor trace is not exported.

The system clock input frequency is used as the reference for all measurements. The PDLO allows for a range of system clock frequencies.

31.1.8.3.5 Tuning Export Clock Frequency Through DPLL

The processor trace export clock can be derived from the CORE DPLL. Selection of the DPLL reference clock is done through the Clock Manager (CM) module. The CM module also provides a means of tuning the frequency of the processor trace export clock by dividing it to 1, 2, or 4 at the PRCM level. It is then possible to slow down the interface clock at the debug subsystem level.

For more information, see the EMU Clock Domain in Chapter 6, *Power, Reset, and Clock Management (PRCM)*.

31.1.8.4 Trace Captured Into On-chip Trace Buffer

The processor trace flow can be re-directed to the on-chip trace buffer (ETB). The ETB provides on-chip storage of trace information using a 64KB RAM memory.

Through its ATB port, the ETB receives trace flow from CoreSight trace source components. The debugger can then access trace information through DAP-APB.

The ETB can act like a circular buffer, that is, continuously capturing and writing data into memory when trace capture is enabled and either its trigger counter is static at 0, or has not yet decremented to 0.

Trace window can be adjusted around a specific trigger spot using ETB trigger counter:

- Trace before
- Trace after
- Trace around

For more information about ETB, see the ARM CoreSight™ Components Technical Reference Manual.

31.1.9 Crash Dump

Because the ETB is mapped to the emulation power domain, the trace history (last 64KB) can be preserved even while the Cortex-A9 processor domain is shut down. For a post-mortem analysis use case, the ETB memory can be dumped at a later stage independent of the processor domain state. Upon crash alert, ETB trace data is typically moved to external memory.

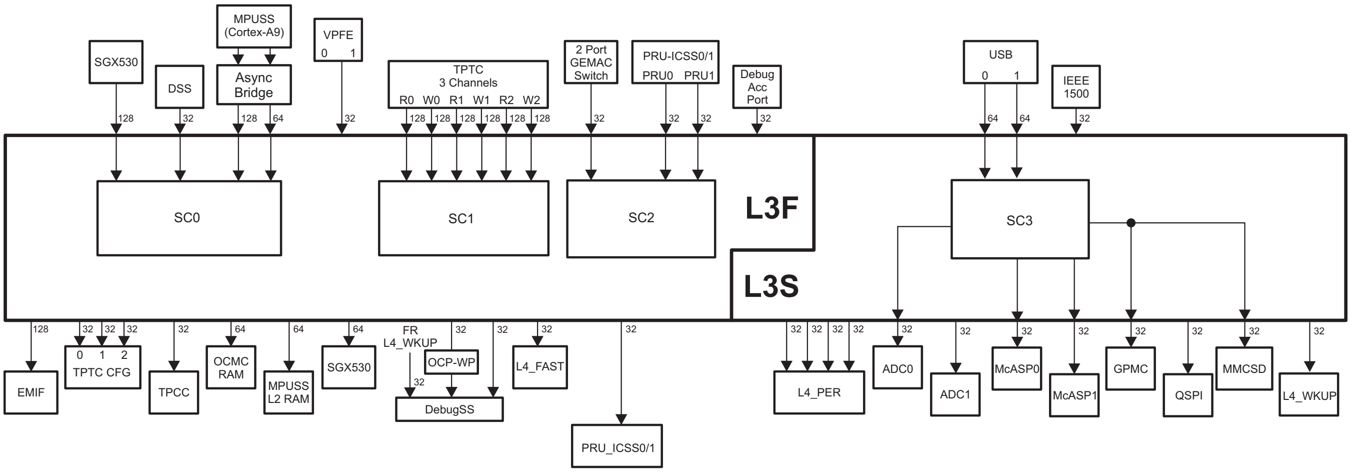
31.2 System Instrumentation

The device supports the following system instrumentation features:

- Real-time software trace (see Section 31.2.4, *Software Instrumentation*)
- OCP target traffic monitoring (see Section 31.2.5, *OCP Watch-Point*)
- OCP target load and master latency monitoring (see Section 31.2.6, *NoC Statistics Collector*)

Figure 31-4 is an overview of the device system instrumentation framework.

Figure 31-4. SoC L3 System Instrumentation Topology



31.2.1 MIPI STM

MIPI-STM is a trace module that aids in software debugging. The main features of this module are:

- Implements MIPI STP protocol (rev 1.0) with the following characteristics:
  - Highly optimized for software-generated traces
  - Automatic timestamping of messages
  - Support for 8-, 16-, and 32-bit data types
- Collects the following information:
  - Software messages
  - Hardware instrumentation trace from hardware agents:
    - OCP-WP
    - L3 NoC CTools System Statistics Collection Units (Statistics Collectors)
- Exports trace data to:
  - Off chip to external trace receiver via device pins
  - On-chip ETB buffer
- Available in 1-, 2-, or 4-pin mode with single- or dual-edge clock, depending on the trace bandwidth requirements and the trace receiver characteristics
- Dedicated 128 × 32-bit FIFO buffer

A maximum of 255 different bus masters can be connected to the STM trace port through a bus arbiter. STP recognizes two distinct modes of tracing, software and hardware types, which use slightly different message combinations to output different types of data. The bus masters can be configured for either type to optimize the system for the different types of trace data.

31.2.2 Trace Exported to an External Trace Receiver

31.2.2.1 Debug Resources Manager

System trace data can be exported to an external trace receiver through the STM module. To achieve this, the debugger or application software must properly program the DRM module.

31.2.2.2 Trace Port Width Configuration

The STM has a configurable export width of 1, 2, or 4 data pins (STM_DATA) plus a dedicated export clock (STM_CLK).

31.2.2.3 Tuning Export Clock Frequency

The device implements two system trace export clock (STM_CLK) generation schemes:

- Trace export clock, generated from programmable DPLL reference clock, shared with application with programmable post-dividers
- Trace export clock, generated from the programmable delay line oscillator (PDLO), embedded in the debug subsystem

31.2.2.3.1 Tuning Export Clock Frequency Through DPLL

The MIPI-STM trace export clock (STM_CLK) can be derived from the CORE DPLL. Selection of the DPLL reference clock is done through the CM module. The CM module also provides a way to tune the STM export clock frequency by dividing it to 1, 2, or 4 at the PRCM level.

31.2.2.3.2 Tuning Export Clock Frequency Through PDLO

The debug subsystem implements a dedicated PDLO module for system trace export clock generation. Because the STM PDLO is functionally equivalent to the processor trace PDLO. For more information about PDLO functionality, see Section 31.1.8.3.3, *Tuning Export Clock Frequency Through PDLO*.

31.2.2.4 Trace Streams Interleaving

Two levels of interleaving system instrumentation flow and arbitration are implemented between instrumentation masters:

- CORE L3 instrumentation interconnect interleaves data coming from the following bus masters:
  - OCP-WP
  - L3 NoC statistics collectors, or software instrumentation (interleaving at the L3 level)
- EMU L3 instrumentation interconnect interleaves data coming from the following bus masters:
  - CORE L3 instrumentation interconnect

31.2.3 Trace Captured into On-chip Trace Buffer

If a trace receiver cannot be attached to the device, or relevant STM trace port pins are unavailable for a particular reason, the user can configure the MIPI-STM module to redirect the STP trace stream to the on-chip trace buffer (ETB) and enable local timestamping. This is accomplished by outputting a local timestamp granularity (LTSG) message, which is a TI addition to the MIPI standard messages.

NOTE: For STM timestamps when output to the ETB, the TS field is no longer the STM FIFO depth, but is the time from the previous message.

Granularity is a function of the instrumentation port clock frequency.

31.2.4 Software Instrumentation

The device provides support for real-time software trace through user-defined message writes to specific, memory mapped register (MMR) locations. Software masters can transmit trace data from the operating system (OS) processes or tasks on 256 different channels, with each channel being defined by the implemented software protocol. The different channels logically group different types of data so that it is easy to filter out the data that is irrelevant to the on-going debugging task. The message structures in STP are optimized to provide an efficient transport for software data through the STM module.

The software masters are:

- Cortex-A9 MPU subsystem
- DAP (for testing purpose)
- Dual PRU processors in PRU-ICSS1
- Dual PRU processors in PRU-ICSS0
- EDMA TPTC WR0 Channels

Each software master has a master-ID assigned to it.

Software messages can be interleaved with other hardware messages. Software messages are intrusive and use both processor cycles and memory.

Table 31-9 describes the master-ID of the software masters.

Table 31-9. STM Message Software Masters

Initiator		MReqMstID			Restriction / Comment
		7	6:02	1:00	
MPU		0	1	0	Cortex-A9 MPU
CS_DAP		0	100	-	STP link testing
PRU0	PRU-ICSS1	0	1100	-	Software messages
	PRU-ICSS0	0	1100	-	
PRU1	PRU-ICSS1	0	1101	-	Software messages
	PRU-ICSS0	0	1101	-	
Wakeup Processor		0	10100	-	Via L4 interconnect
TPTC0_WR		0	11001	-	Data logging

NOTE: The Wakeup Processor can access the instrumentation port via the L4 interconnect. It cannot directly access the instrumentation port via the L3 interconnect.

31.2.5 CTools System Bus Watchpoint and Traffic Monitors (OCP_WP)

The L3 interconnect provides five functional probes, which are embedded and attached to the following L3 targets:

- GPMC
- L4-FAST/SLOW/WAKEUP
- OCMC RAM
- EMIF

The output of all probes is multiplexed together and then sent to the L3 interconnect debug port. A component called OCP-WP is used to collect data from functional probes and then transmit captured data to the STM module. The OCP-WP drives a Probe-ID signal to the L3 interconnect for probe selection. The probe selection is exclusive, meaning that interleaving is not possible.

The OCP-WP provides the following main features:

- Monitoring the OCP traffic originated by all initiators that can access the selected target where the probe is attached
- Filtering OCP monitored bus traffic by:
  - Address range
  - Initiator -ID
  - Transaction type
  - Transaction qualifier
- Generating a trigger upon watch-point match
- Starting and stopping OCP traffic monitoring upon:
  - WP address match
  - External trigger
- OCP-WP messages can be interleaved with software messages
- Programming from:
  - Debugger
  - Application

NOTE: The OCP-WP module is restricted to monitor request flow.

Table 31-10 summarizes the OCP targets that can be monitored by the OCP-WP module and their respective probe-ID.

Table 31-10. L3 Interconnect Functional Probe Mapping

Probe-ID	L3 OCP Target
0	Reserved
1	GPMC
10	L4_FAST
11	L4_SLOW
100	OCMC_RAM
101	L4_WAKEUP
110	EMIF
111	Reserved

The user can program the OCP_WP to extract the traffic from a specific set of initiators (maximum 4 Master-IDs).Table 31-11 shows the Master-ID reported by the L3_MAIN debug port for the device initiators

Table 31-11. L3 Master ID Mapping (Debug View)

Initiator	6-bit MConnID (Debug)
MPUSS M2 (64-bit)	0x01
DAP	0x04

31.2.6 L3 NoC Statistics Collector

The L3 interconnect supports a built-in performance monitoring feature by implementing a statistics collector (STATCOLL) component, which computes traffic statistics within a user-defined window and periodically reports to the user through the MIPI-STM interface. Four STATCOLL instances are instantiated in the device:

- Load monitoring, see Section 31.2.6.1, *OCP Target Load Monitoring*, for more information
- Master latency monitoring

Statistics collectors can report:

- Average burst length in bytes/packet per sampling window
- Average throughput in bytes per cycle
- Link occupancy on the request link (for store transactions) during a sampling window
- Link occupancy on the response link (for load transactions) during a sampling window
- Arbitration conflict cycles on the request link
- Initiator busy cycles on the response link
- Histogram of payload length in bytes (for example, 0–16 , 16–32, 32–128) for each sampling window.

The performance metrics are interleaved with software instrumentation data at the L3 interconnect level.

The performance monitoring probes implement three main functions:

- Events detection
- Transactions filtering
- Aggregation

The probes can be configured to detect the events summarized in Table 31-12.

Table 31-12. Performance Monitoring Events Detection

Event	Definition
NONE	No event selected
ANY	Any clock cycles
TRANSFER	Word has been accepted by the receiver
WAIT	Transfer has been initiated but the transmitter currently has no data to send
BUSY	Receiver applies flow control
PKT	Transfer of a new packet header
DATA	Transfer of a payload word
IDLES	No communication over the link
LATENCY	Debug bit detection

The probes can be configured to filter the traffic based on the criteria summarized in Table 31-13.

Table 31-13. Performance Filtering Options

Filters	Comments
Master address	Mask and match
Slave address	
User Info	
Read	Opcode is a load
Write	Opcode is a store
Error	-

The probes implement a user-defined set of counters that aggregate the events sampled by the detector and filtered according to the user setup.

NOTE: Statistics collectors counter values are not accessible by application software.

The master address mapping for all statistics collectors are summarized in Table 31-14.

Table 31-14. Statistics Collector Master Address Mapping

Table 31-16 summarizes the performance probe aggregation modes.

Table 31-16. Performance Filtering Options

Aggregation Mode	Description
FILTER_HIT	The counter increments by 1 when filter hits.
MIN_MAX_HIT	The counter increments by 1 when the filter hits and the sleeted event information is within range. • Payload length (bytes) • Pressure value • Request and response latency (clock cycles)
EVT_INFO	The selected event information is added to the counter value when the filter hits.
AND_FILTER	The counter increments by 1 when all unit filters hit
OR-FILTER	The counter increments by 1 when at least one unit filter hit
SUM_REQ_EVT	The counter sums the events from any request port
SUM_RSP_EVT	The counter sums the events from any response port
SUM_ALL_EVT	The counter sums the events from any port.
EXT_EVT	The counter increments by 1 when selected external event input signal is sampled high.

31.2.6.1 OCP Target Load Monitoring

The L3 interconnect uses performance monitoring probes on target (slave) interfaces. The OCP traffic statistics are computed within a user-defined window and periodically reported to the user through the MIPI-STM interface.

The performance metrics, the software events, and the system hardware events being exported through a unified export channel, it allows correlating latency trends versus on-going execution and system context.

31.2.6.2 Statistics Collectors Configuration

The device instantiates four statistics collectors in the L3 interconnect. Table 31-17, Table 31-18, Table 31-19, Tables below, and Tables below describe the performance probes and configuration for each statistics collector.

All the statistic collectors will dump frames:

- At slave address 0x1F (DEBUGSS). This cannot be changed.
- By default at slave offset 0x800 inside DEBUGSS address range.

Table 31-17. Statistics Collector Counters

statcoll	Number of Counters	Domains	Bits of Counters	Identifier
statcoll_0	4	L3 Fast	12	0x0
statcoll_1	6	L3 Fast	12	0x1
statcoll_2	4	L3 Fast	12	0x2

31.2.7 Hardware Masters

The Master-ID of Hardware message reaching to STM module is described in Table 31-22.

Table 31-22. Master-ID for Hardware Masters

Initiator	MReqMstID			Restriction / Comment
	7	6:02	1:00	
OCP_WP	1	0	0	Traffic probe
OCP_WP	1	1	0	DMA profiling
OCP_WP	1	10	0	System event
Stat_Coll 0	1	11100	0	Statistics Collector 0
Stat_Coll 1	1	11101	0	Statistics Collector 1
Stat_Coll 2	1	11110	0	Statistics Collector 2
Stat_Coll 3	1	11111	0	Statistics Collector 3

31.3 Concurrent Debug Mode

The debugger or application software can program the DRM to route a specific debug function to each device debug port pin. Because of the limited number of pins allocated to debug, debug and trace source signals are multiplexed.

Table 31-23 summarizes the trace port configuration.

Table 31-23. Trace Port Configuration

Pin Name	Internal Signal Name	I/O	Trigger	JTAG 20-pin Header	CS_TPIU (MPU Trace)		STM (System Trace)
					8-bit Mode	10-bit Mode	
dmp_emu11	EMU11	O			TRACEDATA[7]	TRACEDATA[9]	STM_DATA[x]/ STM_CLK(1)
dmp_emu10	EMU10	O			TRACEDATA[6]	TRACEDATA[8]	STM_DATA[x]/ STM_CLK(1)

(1) STM data and clock can be configured on any debug pin that is available to support various devices with limited pin options.

Table 31-23. Trace Port Configuration (continued)

Pin Name	Internal Signal Name	I/O	Trigger	JTAG 20-pin Header	CS_TPIU (MPU Trace)		STM (System Trace)
					8-bit Mode	10-bit Mode	
dmp_emu9	EMU9	O			TRACEDATA[5]	TRACEDATA[7]	STM_DATA[x]/ STM_CLK (1)
dmp_emu8	EMU8	I/O			TRACEDATA[4]	TRACEDATA[6]	STM_DATA[x]/ STM_CLK (1)
dmp_emu7	EMU7	I/O			TRACEDATA[3]	TRACEDATA[5]	STM_DATA[x]/ STM_CLK (1)
dmp_emu6	EMU6	I/O			TRACEDATA[2]	TRACEDATA[4]	STM_DATA[x]/ STM_CLK (1)
dmp_emu5	EMU5	I/O			TRACEDATA[1]	TRACEDATA[3]	STM_DATA[x]/ STM_CLK (1)
dmp_emu4	EMU4	O			TRACEDATA[0]	TRACEDATA[2]	STM_DATA[x]/ STM_CLK (1)
dmp_emu3	EMU3	O			TRACECTL	TRACECTL	STM_DATA[x]/ STM_CLK (1)
dmp_emu2	EMU2	O			TRACECLK	TRACECLK	STM_DATA[x]/ STM_CLK (1)
dmp_emu1	EMU1	I/O	Trigger 1	EMU1		TRACEDATA[1]	STM_DATA[x]/ STM_CLK (1)
dmp_emu0	EMU0	I/O	Trigger 0	EMU0		TRACEDATA[0]	STM_DATA[x]/ STM_CLK (1)

NOTE: The configuration of the trace port must comply with Table 31-23; otherwise, it will be ignored by DRM hardware. For example, if Trigger0 is programmed on EMU3 and Trigger1 is programmed on EMU4, this configuration will be ignored.

The application or debugger software can program the DRM to route a specific debug function to each debug port pin. The programming model is making provision for debug support enhancement and reuse by other platforms.

Table 31-24 summarizes the concurrent debug and trace use cases.

Table 31-24. Concurrent Debug and Trace

Debug Use case	Concurrent Debug flows	Debug pins	Trace pins		
		Triggers	Data	Control	Clock
0	PTM		10	1	1
	STM				
	Triggers				
1	PTM		8	1	1
	STM				
	Triggers	2			
2	PTM		8	1	1
	STM		1	-	1
	Triggers				
3	PTM		3	1	1
	STM		4	-	1
	Triggers	2			

31.4 Memory Mapping

Table 31-25 summarizes the memory mapping of the debug modules.

Table 31-25. Debug Modules Memory Mapping

Appendix A

SPRUHL7H–April 2014–Revised January 2018

Glossary

Numerical

2D— Two dimensional

3D— Three dimensional

3GPP— 3rd Generation Partnership Project

A

ABS— Absolute value

ACA —Accessory Charger Adaptor

ADC— Analog-to-digital converter/conversion

A-dev —A USB OTG device with an A-plug connected to its port (ID pin grounded). Default host

ADP —Attach Detection Protocol: detects USB OTG attach/detach events.

AEW— Adaptive multirate

AHB— Advanced high-performance bus

AMR— Adaptive multirate; also Audio modem riser: An Intel specification that defines a new architecture for the design of motherboards.

APB— Advanced peripheral bus

APE— Applicative processor engine

API— Application programming interface; also ARM port interface

ARAU— Auxiliary register arithmetic unit

ARGB— Alpha, red, green, blue

ASIC— Application-specific integrated circuit: A chip built for a specific application. In the context of this document, ASIC refers to the FPGA that resides on the EVM board.

ASCII— American standard code for information

ATR— Answer to reset

AVC— Advanced video coding (MPEG4 - Part 10 also known as H264)

AXI— Advanced extensible interface

B

BB— Busy bus

BCD— Binary-coded decimal: A representation of decimal digits (0–9) using a nibble that uses a certain number of bits. For example, using 4 bits, two BCDs can be packed into 1 byte.

B-dev —A USB OTG device with a B-plug connected to its port (ID pin floating). Default peripheral.

BER — Bit Error Rate.

BGA— Ball grid array

BGAPTS— Band gap voltage and temperature sensor

BGT— Block guard time

BIOS— Built-in operating system

BIST— Built-in self-test

Bluetooth®— A short-range radio technology designed to simplify communications among network devices and between devices and the Internet. It also simplifies data synchronization between network devices and other computers.

BPP— Bits per pixel

BTA— Bus turn around

C

CALU— Central arithmetic logic unit

CAVLC— Context-adaptive variable length coder

CAVLD— Context-adaptive variable length decoder

CBUFF— Circular buffer

CCP— Compact camera port

CDC — Communication Device Class: USB device class.

CDL— Controlled delay line

CE— Chip enable

CH— Configuration header. To use settings other than ROM code defaults, (that is, clock frequencies, SDRAM/DDRAM settings, or GPMC settings).

CID— Card identification number

CIF— Common intermediate format. A video format used in video conferencing systems that easily supports both NTSC and PAL signals. CIF is part of the ITU H.261 video conferencing standard. It specifies a data rate of 30 fps, with each frame containing 288 lines and 352 pixels per line.

CLE— Command latch enable

CLK— Clock

CLUT— Color look-up table

CMOS— Complementary metal oxide semiconductor

CMT— Cellular mobile telephone

Codec— Coder/decoder or compression/decompression: A device that codes in one direction of transmission and decodes in another direction of transmission.

ConnID— Connection identifier: An initiator module identifier. A ConnID transmitted in-band with the request and is used for protection and error logging mechanism.

CP15— Coprocessor 15: This coprocessor controls the operation and configuration of the TI925T.

CPSR— Current program status register

CPU— Central processing unit: The CPU is the portion of the processor involved in arithmetic, shifting, and Boolean logic operations, as well as the generation of data and program memory addresses. The CPU includes the CALU, the multiplier, and the ARAU.

CRC— Cyclic redundancy check

CS— Chip-select

CTRL— Control

CVBS— Composite video broadcast signal

CWT— Command wire tracer

D

D2D— Die-to-die

DAC— Digital-to-analog converter

DBB— Digital baseband

DBI— Display date interface

DCS— Display command set

DCO— Digitally controlled oscillator

DCT— Discrete cosine transform: A fast Fourier transform used to manipulate compressed still and moving picture data.

DDR— Dual data rate

DE— Date enable

DFF— Digital flip-flop

DFT— Design for test

DI— Data identifier

DISPC— Display controller

DLL— Delay-locked loop

DMA— Direct memory access: A mechanism whereby a device other than the host processor contends for and receives mastery of the memory bus so that data transfers can occur independent of the host.

DMC— Data memory controller

DPCM— Differential pulse code modulation

DPD, DPDM— Deep power-down mode

DPF— Dynamic power framework

DPI— Display parallel interface. Digital implementation of PLL

DPLL— Digital phase-locked loop

DRD— Dual role device: USB Host and Peripheral capable.

DRDY— Data ready

DRM— Digital rights management

DS — Down Stream (A USB port facing from a Host or Hub to a Device/Peripheral).

DSI— Display serial interface

DSP— Digital signal processor: A semiconductor that manipulates discrete or discontinuous electrical impulses in a manner that implements a desired algorithm.

DSS— Display subsystem

DT— Data type

DVFS— Dynamic voltage and frequency scaling

E

EAV— End of active video

ECC— Error checking and correction; also error correction code.

ED— Endpoint descriptor

EDC— Error detection code

eFuse— Electrical fuse: A one-time programmable memory location usually set at the factory

EHCI— Enhanced host controller interface

EMC— External memory controller

EMI— Electromagnetic interference

EMV— Initial letters of Europay, MasterCard, and VISA, the three companies which originally cooperated to develop the EMV standard

EOF— End of frame

EOI —End of interrupt

EOP —End of packet

EOT— End of transfer

EP — Endpoint: USB communication channel between the USB link partners carrying a single transfer type (BULK, ISOCH, INT, or CONTROL) and bus sharing arbitration scheme.

ES— Erase status

ETB— Embedded trace buffer

ETSI— European Telecommunications Standard Institute

ETM— Embedded trace macrocell

F

FC— Frame counter

FE— Framing error: An error that occurs when the asynchronous serial port receives a data character that does not have a valid stop-bit.

FIFO— First in first out: A queue; a data structure or hardware buffer from which items are removed in the same order they were put in. A FIFO is useful for buffering a stream of data between a sender and receiver which are not synchronized; that is, the sender and receiver are not sending and receiving at exactly the same rate. If the rates differ by too much in one direction for too long, the FIFO becomes either full (blocking the sender) or empty (blocking the receiver).

FIQ— Fast interrupt request

FlatLink™ 3G— A Texas Instruments display interface protocol

FS— Frame synchronization or Full-Speed USB data rate (12 Mbps).

FSM— Finite state-machine: A model of computation consisting of a set of states, a start state, an input alphabet, and a transition function that maps input symbols and current states to a next state.

FSR— Fault status register

FT— Feed through

G

GDD— Generic distributed DMA

GP device— General-purpose device

GPIO— General-purpose input/output: Pins that can accept input signals and/or send output signals but are not linked to specific uses.

GPMC— General-purpose memory controller

GSM— Global system for mobile communications

H

HC— Host controller

HCD — Host Controller Driver, designates the USB SW.

HDTV— High-definition television

HFP— Horizontal Front Porch

HNP — Host Negotiation Protocol, OTG extension to swap USB host and peripheral roles.

HPI— Host port interface

HS — High-Speed USB data rate (480 Mbps).

HSEC— Horizontal sync end code

HSSC— Horizontal sync start code

HSYNC— Horizontal synchronization: A bidirectional horizontal timing signal occurring once per line with a pulse width defined as an integral number of FCLK periods. Synchronization signals can be used to enable retrace of the electron beam of a display screen. Also HS.

HSW— Horizontal Synchronization Pulse Width

HVGA— Half-size video graphics array. One-half the resolution of VGA

HW, H/W— Hardware

HWA— Hardware accelerators

I

I^{2}C— Inter-integrated circuit: A multimaster bus where multiple chips can be connected. Each chip can act as a master by initiating a data transfer.

I2S— Inter-IC sound: A digital audio interface standard.

IA— Initiator agent, also Identifier address

IC— Integrated circuit

ICR— Intersystem communication registers

IF— Interface

INT— Interrupt: A signal sent by hardware or software to a processor requesting attention. An interrupt tells the processor to suspend its current operation, save the current task status, and perform a particular set of instructions. Interrupts communicate with the operating system and prioritize tasks to be performed.

INTC— Interrupt controller

I/O— Input/output

IP— Intellectual property

IPC— Interprocessor communication. Also referred to as *mailbox.*

IrDA— Infrared Data Association: Represents the group of device manufacturers that developed a standard for transmitting data via infrared light waves.

IRQ— Interrupt request: IRQs are hardware lines over which devices can send interrupt signals to the microprocessor.

ISO— Isochronous: This refers to processes where data must be delivered within certain time constraints. For example, multimedia streams require an isochronous transport mechanism to ensure that data is delivered as fast as it is displayed and to ensure that the audio is synchronized with the video. Also, *International Standards Organization.*

ISOCH — Isochronous transfer type.

ISP— Image sensing product; also image signal processor

ISR— Interrupt service routine: A function or set of functions that are called when an interrupt is encountered.

ITP — Isochronous Timestamp Packet: USB SS micro-frame boundary packets.

ITU— International Telecommunications Union

IVA— Image and video accelerator

J

J — Logical USB2 line level: Diff1 in HS/FS, Diff0 in LS. Idle FS/LS bus state.

JPEG— Joint Photographics Experts Group

JTAG— Joint Test Action Group: The JTAG was formed in 1985 to develop economical test methodologies for systems designed around complex integrated circuits and assembled with surface-mount technologies. The group drafted a standard that was subsequently adopted by IEEE as IEEE Standard 1149.1-1990, IEEE Standard Test Access Port, and Boundary-Scan Architecture.

K

K — Logical USB2 line level: Diff0 in HS/FS, Diff1 in LS. Resume bus state.

Kb— Kilobits

KB— Kilobyte, 1024 B

Kbps— Kilobits per second

L

L1— Level 1 cache/memory

L2— Level 2 cache/memory

L3— First level of interconnect in OMAP platform

L4— Second level of interconnect in OMAP platform

LCD— Liquid crystal display: A display that uses two sheets of polarizing material with a liquid crystal solution between them.

LCh— Logical DMA channel

LDM— Load multiple

LDO— Low dropout

LFPS —Low-Frequency Periodic Signal.

LH— Local host

LINK— Link layer device

LLP— Low-level protocol

LMP —Link Management Packet.

LP— Low power, operation mode for PHY

LPDDR— Low-power, double-data rate (SDRAM)

LPM— Low-power mode

LPP— Lines per panel

LPSDR— Low-power, single-data rate (SDRAM)

LRC— Longitudinal redundancy check

LRU— Least recently used

LS— Level shifter; also low speed or Low-Speed USB data rate (1.5 Mbps).

LSB— Least-significant bit

LUT— Look-up table

LVDS— Low-voltage differential signaling

M

Mailbox— See *IPC*

Mb— Megabit

Mbps— Megabits per second

McBSP— Multichannel buffered serial port: An enhanced buffered serial port that includes the following standard features: buffered data registers, full duplex communication, and independent clocking and framing for receive and transmit. In addition, the McBSP includes the following enhanced features: internal programmable clock and frame generation, multichannel mode, and general-purpose I/O.

MCSPI— Multichannel serial port interface

MCP— Multi-chip package

MCU— Microcontroller unit (refers to the MPU)

MDDR— Mobile double-data-rate SDRAM, dedicated to mobile applications

MHz —Megahertz.

MIPI®— Mobile industry processor interface

MMC— Multimedia card

MMC/SD— Multimedia card/secure data

MMR —Memory Mapped Register.

MMU— Memory management unit: The MMU performs virtual-to-physical address translations, performs access permission checks for access to the system memory, and provides the flexibility and protection required for the OS to manage a shared physical memory space between the two processors.

MPEG— Motion Pictures Expert Group: A compression scheme for full-motion video.

MPEG1— The first MPEG compression scheme specification

MPEG4— The most current MPEG compression scheme specification, intended for very narrow bandwidths.

MPU— Microprocessor unit

MS— Mobile station

MSB— Most-significant bit: The highest order bit in a word. The plural form (MSBs) refers to a specified number of high-order bits, beginning with the highest order bit and counting to the right. For example, the 8 MSBs of a 16-bit value are bits 15 through 8.

MSC —Mass Storage Class.

MUX— Multiplex/multiplexer

Muxed pin— A pin is muxed when its pin control register field can be reconfigured by software to change the function associated with the pin.

MuxMode— A 3-bit field of the pin control register field which enables to change the mode. Mode programming is assumed by software and selects a function on the device external interface.

N

N/A— Not applicable

NAK— Not acknowledged

NAND— NAND flash memory that is a high-capacity, low-cost, embedded, permanent data storage solution

NF— Noise filter

NMI— Nonmaskable interrupt: An interrupt that cannot be masked or disabled.

NOP— No operation (DSP/CPU instruction)

NR— Noise reduction

NSC— National Semiconductor Corporation

NTSC— National Television System Committee (television broadcast system)

O

OCM— On-chip memory

OCO— One change only

OCP— Open-core protocol

OCPI— Open-core protocol interface

OEM— Original equipment manufacturer

OGL— Open GL (programming API) enable

OHCI— Open host controller interface: This is an industry standard USB host controller interface.

OMAP— An open software and hardware platform targeted at second- and third-generation cellular phones with multimedia capabilities.

OneNand™ — A memory chip based on NAND architecture integrating SRAM buffers and NOR logic interface. It combines the advanced data storage function of NAND flash with fast read speed function of NOR flash.

OTG— On-the-go (USB 2.0 specification)

P

PBIAS— PMOS bias transistor to provide the bias voltage to extended drain I/Os

PCB— Printed circuit board

PCLK— Pixel clock

PCM— Pulse code modulation: A technique for digitizing speech by sampling the sound waves and converting each sample into a binary number.

PDA— Personal digital assistant

PDE— Personal down enable

PE— Packet end

PF— Packet footer

PH— Packet header

PG— Protection group

PGA— Pin grid array

PHY— Physical layer device

PI— Packet identifier

PID— Protocol identifier: The PID register is used in Windows CE mode only.

PIPE —PHY Interface for PCI Express, also used in USB3 SS PHY interface.

PIPE3 —PIPE Interface for USB3 SS PHY interface.

PLD— Programmable logic device

PLL— Phase-locked loop: A closed loop frequency control system whose function is based on the phase-sensitive detection of the phase difference between the input signal and the output signal of the controlled oscillator (CO).

PMC— Program memory controller

POP— Package-on-package technology

PMP— Power management port

POR— Power-on reset

PPI— Physical layer protocol interface

PPS— Protocol and parameter selection

PRCM— Power, reset, and clock management

PRM— Power and reset manager

PS— Packet start

PSA— Parallel signature analyzer

PT— Packet type

PVT— Process, voltage, and temperature (that is, PVT dispersion)

PWB— Printed wiring board

PWM— Pulse width modulation

PWR— Power

Q

QCIF— Quarter common intermediate format: A video conferencing format that specifies data rates of 30 fps, with each frame containing 144 lines and 176 pixels per line. This is one-fourth the resolution of CIF. QCIF support is required by the ITU H.261 video conferencing standard.

QVGA— Quarter video graphics array (one-fourth the resolution of VGA).

R

R— Read only

RAM —Random Access Memory.

RBL— Read buffer logic

RC— Read-Clear

RC/W— Read-Clear / Write

RC/W1C— Read-Clear / Write 1 to Clear

RC/W1CP— Read-Clear / Write 1 to Clear (Privilege Only)

RC/W1S— Read-Clear / Write 1 to Set

RC/W1SP— Read-Clear / Write 1 to Set (Privilege Only)

RC/WP— Read-Clear / Write (Privilege Only)

RCP— Read-Clear (Requires Privilege)

RCP/W— Read-Clear (Privilege Only) / Write

RCP/W1C— Read-Clear (Privilege Only) / Write 1 to Clear

RCP/W1CP— Read-Clear (Privilege Only) / Write 1 to Clear (Privilege Only)

RCP/W1S— Read-Clear (Privilege Only) / Write 1 to Set

RCP/W1SP— Read-Clear (Privilege Only) / Write 1 to Set (Privilege Only)

RCP/WP— Read-Clear (Privilege Only) / Write (Privilege Only)

RFBI— Remote frame buffer interface

RFU— Reserved for future use

RGB— Red, green, blue

RGBA— Red, green, blue, alpha

ROM— Read only memory: A semiconductor storage element containing permanent data that cannot be changed.

RP— Read (Requires Privilege)

RP/W— Read (Privilege Only) / Write

RP/W1C— Read (Privilege Only) / Write 1 to Clear

RP/W1CP— Read (Privilege Only) / Write 1 to Clear (Privilege Only)

RP/W1S— Read (Privilege Only) / Write 1 to Set

RP/W1SP— Read (Privilege Only) / Write 1 to Set (Privilege Only)

RP/WP— Read (Privilege Only) / Write (Privilege Only)

RST— Reset

RT— Real-time

RVLC— Reversible variable length coder

RVLD— Reversible variable length decoder

R/W— Read / Write

R/W1C— Read / Write 1 to Clear

R/W1CP— Read / Write 1 to Clear (Privilege Only)

R/W1S— Read / Write 1 to Set

R/W1SP— Read / Write 1 to Set (Privilege Only)

R/WP— Read / Write (Privilege Only)

RX— Receive/receiver

S

S3220— Abbreviation of Sonics3220. It refers to the L4 interconnect.

SAM— Shared access mode: The mode that allows both the DSP and the host to access host port interface (HPI) memory. In this mode, asynchronous host accesses are synchronized internally, and, in case of conflict, the host has access priority and the DSP waits one cycle.

SAR— Save and restore: Hardware context saving for power saving

SAV— Start of active video

SCCB— Serial camera control interface: 3-wire and 2-wire serial bus defined and deployed by Omnivision Technologies, Inc.

SCL— Serial clock: Programmable serial clock used in the I^{2}C interface. Also SCLK.

SCM— Scan combiner module; also statistic collection module

SCP— Serial configuration port

SD— Starting delimiter

SDA— Serial data: Serial data bus in the I^{2}C interface.

SDI— Serial display interface

SDIO— Secure digital input/output

sDMA— System direct memory access

SDR— Single data rate

SDRC— SDRAM controller

SDRAM— Synchronous dynamic random access memory

SDTI— System debug trace interface

SDTV— Standard digital television

SE — Single-Ended: USB state based on individual lines’ state (D+/D-).

SE0 — Single-Ended zero line state where D+=D-=0. Used for reset, FS/LS EOP.

SER — Soft Error Rate.

SGX— Abbreviation for graphic accelerator (GFX in ES1.0)

SIM— Subscriber identity module

SIMD— Single instruction multiple data

SILVS— Scalable low-voltage signaling

SMS— SDRAM memory scheduler

SMX— Abbreviation of SonicsMX. It refers to the L3 interconnect.

SNR— Signal-to-noise ratio

SOC — System On a Chip.

SOF— Start of frame

SOT— Start of transmission

SRAM— Static random access memory. Fast memory that does not require refreshing, as DRAM does. It is more expensive than DRAM, though, and is not available in as high a density as DRAM.

SRG— Sample rate generator

SRP — Session Request Protocol. OTG extension to wake-up a system, allowing a B-device to request an A-device to turn on the VBUS power and start session.

SRRP— Session RAM restoration pointer

SS— Subsystem or Super Speed

SSC — Spread Spectrum Clocking.

SSR— Serial synchronous receiver

SST— Serial synchronous transmitter

ST— Start timer

STM— Synchronous transfer mode; also store multiple

STN— Super-Twist Nematic: A technique for improving LCD display screens by twisting light rays.

SVGA— Super video graphic adapter

SW— Software

SWI— Software interrupt

T

TC— Traffic controller. Allows asynchronous operation among the external memory interface, the MPU, and the DSP.

TCK— Test clock

TD— Transfer descriptor

TDM— Time division multiplex/multiplexing: The process by which a single serial bus is shared by multiple devices with each device taking turns to communicate on the bus. The total number of time slots (channels) depends on the number of devices connected. During a time slot, a given device may talk to any combination of devices on the bus.

TFT— Thin film transistor. A type of LCD flat panel display screen in which each pixel is controlled by one to four transistors.

TLB— Translation lookaside buffer: A cache that contains entries for virtual-to-physical address translation and access permission checking.

TLL— Transceiverless link: This is logic that lets the user connect two USB transceiver interfaces together directly without the use of differential transceivers.

TM— Target module: A target module cannot generate read/write requests to the chip interconnects, but it responds to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers).

TOC— Table of contents

TRB —Transfer Request Block.

TRM— Technical reference manual

TRX— USB transceiver: The USB analog driver/receiver.

TTB— Translation table base: It points to the base of a table in physical memory that contains section and page table descriptors.

TWL— Table walking logic

TX— Transmit/transmitter

U

UART— Universal asynchronous receiver/transmitter: Another name for the asynchronous serial port.

UAS —USB-Attached SCSI: ANSI standard for USB-attached storage.

UICC— Universal integrated circuit card

ULPM— Ultra-low power mode

ULPI— UTMI+ low pincount interface

ULPS— Ultra-low power state

UMC— United memory controller

UNP— Unpredictable

US — Upstream facing from a device (or hub) to the host (or a hub).

USAR— Universal synchronous/asynchronous receiver

USART— Universal synchronous/asynchronous receiver/transmitter

USB— Universal serial bus: An external bus standard that supports data transfer rates of 12M bps (12 million bits per second). A single USB port can be used to connect up to 127 peripheral devices.

USB IF —USB Implementers Forum. The governing organization that develops and maintains the USB specifications and compliance standard. www.usb.org

UTMI —USB 2.0 PHY Transceiver Macrocell Interface specification.

UTMI+ —UTMI plus extensions to the UTMI spec. Among other improvements, it defines the PHY interface for OTG 2.0.

V

VA— Volt-amps: A form of power management. A VA rating is the volts rating multiplied by the amps (current) rating, used to indicate the output capacity of an uninterruptible power supply (UPS) or other power source.

VC— Virtual channel

VENC— Video encoder

VESA— Video Electronics Standards Association

VFP— Vertical front porch

VGA— Video graphics array: An industry standard for video cards.

VLC— Variable length decoder

VLCD— Variable length coding and decoding coprocessor

VLD— Variable length coder

VMODE— Bi-level voltage control interface

VPBE— Video processing back end

VSEC— Vertical synchronization end code

VSSC— Vertical synchronization start code

VSYNC, VS— Vertical synchronization: A bidirectional vertical timing signal occurring once per frame with a pulse-width defined as an integral number of lines (half-lines for interlaced mode).

W

W— Write

W1C— Write 1 to Clear

W1CP— Write 1 to Clear (Requires Privilege)

W1S— Write 1 to Set

W1SP— Write 1 to Set (Requires Privilege)

WBL— Write buffer logic

WC— Word count

WD— Watchdog: A timer that requires the user program or OS periodically write to the count register before the counter underflows.

WDT— Watchdog timer

WLAN— Wireless local area network

WMV— Windows media video

WMA— Windows media audio

Word16— 16-bit word

Word32— 32-bit word

WP— Write (Requires Privilege)

WSS— Wide-screen signaling

WWT— Work waiting time

X

XGA, XVGA— Extended graphics array

xHC — Host Controller, designates the USB HW that implements the xHCI specification.

xHCI — eXtensible Host Controller Interface. The specification that defines the register level interface for host controller.

XIP— Execution in place

Y

YUV— Luminance-Bandwidth-Chrominance

IMPORTANT NOTICE FOR TI DESIGN INFORMATION AND RESOURCES

Texas Instruments Incorporated ('TI") technical, application or other design advice, services or information, including, but not limited to, reference designs and materials relating to evaluation modules, (collectively, "TI Resources") are intended to assist designers who are developing applications that incorporate TI products; by downloading, accessing or using any particular TI Resource in any way, you (individually or, if you are acting on behalf of a company, your company) agree to use it solely for this purpose and subject to the terms of this Notice.

TI's provision of TI Resources does not expand or otherwise alter TI's applicable published warranties or warranty disclaimers for TI products, and no additional obligations or liabilities arise from TI providing such TI Resources. TI reserves the right to make corrections, enhancements, improvements and other changes to its TI Resources.

You understand and agree that you remain responsible for using your independent analysis, evaluation and judgment in designing your applications and that you have full and exclusive responsibility to assure the safety of your applications and compliance of your applications (and of all TI products used in or for your applications) with all applicable regulations, laws and other applicable requirements. You represent that, with respect to your applications, you have all the necessary expertise to create and implement safeguards that (1) anticipate dangerous consequences of failures, (2) monitor failures and their consequences, and (3) lessen the likelihood of failures that might cause harm and take appropriate actions. You agree that prior to using or distributing any applications that include TI products, you will thoroughly test such applications and the functionality of such TI products as used in such applications. TI has not conducted any testing other than that specifically described in the published documentation for a particular TI Resource.

You are authorized to use, copy and modify any individual TI Resource only in connection with the development of applications that include the TI product(s) identified in such TI Resource. NO OTHER LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE TO ANY OTHER TI INTELLECTUAL PROPERTY RIGHT, AND NO LICENSE TO ANY TECHNOLOGY OR INTELLECTUAL PROPERTY RIGHT OF TI OR ANY THIRD PARTY IS GRANTED HEREIN, including but not limited to any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information regarding or referencing third-party products or services does not constitute a license to use such products or services, or a warranty or endorsement thereof. Use of TI Resources may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

TI RESOURCES ARE PROVIDED "AS IS" AND WITH ALL FAULTS. TI DISCLAIMS ALL OTHER WARRANTIES OR REPRESENTATIONS, EXPRESS OR IMPLIED, REGARDING TI RESOURCES OR USE THEREOF, INCLUDING BUT NOT LIMITED TO ACCURACY OR COMPLETENESS, TITLE, ANY EPIDEMIC FAILURE WARRANTY AND ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND NON-INFRINGEMENT OF ANY THIRD PARTY INTELLECTUAL PROPERTY RIGHTS.

TI SHALL NOT BE LIABLE FOR AND SHALL NOT DEFEND OR INDEMNIFY YOU AGAINST ANY CLAIM, INCLUDING BUT NOT LIMITED TO ANY INFRINGEMENT CLAIM THAT RELATES TO OR IS BASED ON ANY COMBINATION OF PRODUCTS EVEN IF DESCRIBED IN TI RESOURCES OR OTHERWISE. IN NO EVENT SHALL TI BE LIABLE FOR ANY ACTUAL, DIRECT, SPECIAL, COLLATERAL, INDIRECT, PUNITIVE, INCIDENTAL, CONSEQUENTIAL OR EXEMPLARY DAMAGES IN CONNECTION WITH OR ARISING OUT OF TI RESOURCES OR USE THEREOF, AND REGARDLESS OF WHETHER TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

You agree to fully indemnify TI and its representatives against any damages, costs, losses, and/or liabilities arising out of your non-compliance with the terms and provisions of this Notice.

This Notice applies to TI Resources. Additional terms apply to the use and purchase of certain types of materials, TI products and services. These include; without limitation, TI's standard terms for semiconductor products http://www.ti.com/sc/docs/stdterms.htm), evaluation modules, and samples (http://www.ti.com/sc/docs/sampterms.htm).

Mailing Address: Texas Instruments, Post Office Box 655303, Dallas, Texas 75265
