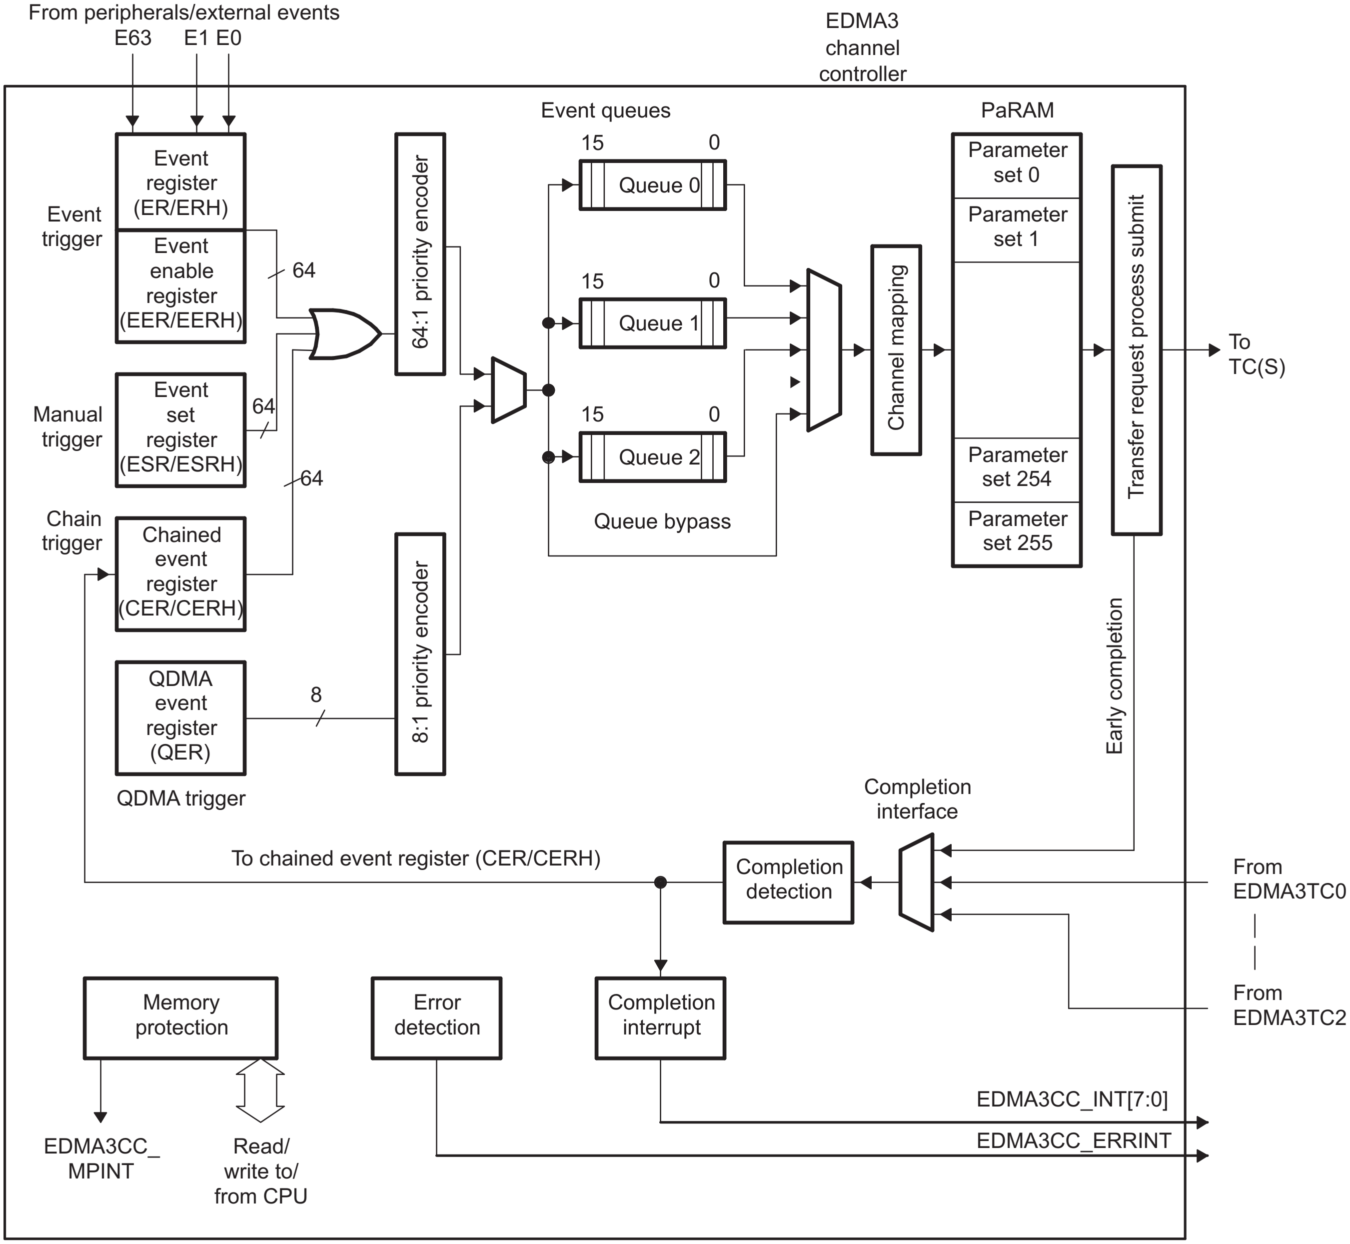
The EDMA3CC includes two channel types: DMA channels (64 channels) and QDMA channels (8 channels).

Each channel is associated with a given event queue/transfer controller and with a given PaRAM set. The main thing that differentiates a DMA channel from a QDMA channel is the method that the system uses to trigger transfers. See Section 10.3.4.

Figure 10-4. EDMA3 Channel Controller (EDMA3CC) Block Diagram



A trigger event is needed to initiate a transfer. A trigger event may be due to an external event, manual write to the event set register, or chained event for DMA channels. QDMA channels auto-trigger when a write to the trigger word that you program occurs on the associated PaRAM set. All such trigger events are logged into appropriate registers upon recognition.

Once a trigger event is recognized, the appropriate event gets queued in the EDMA3CC event queue. The assignment of each DMA/QDMA channel to an event queue is programmable. Each queue is 16 events deep; therefore, you can queue up to 16 events (on a single queue) in the EDMA3CC at a time. Additional pending events that are mapped to a full queue are queued when the event queue space becomes available. See Section 10.3.11.

If events on different channels are detected simultaneously, the events are queued based on a fixed priority arbitration scheme with the DMA channels being higher priority events than the QDMA channels. Among the two groups of channels, the lowest-numbered channel is the highest priority.

Each event in the event queue is processed in FIFO order. When the head of the queue is reached, the PaRAM associated with that channel is read to determine the transfer details. The TR submission logic evaluates the validity of the TR and is responsible for submitting a valid transfer request (TR) to the appropriate EDMA3TC (based on the event queue to the EDMA3TC association, Q0 goes to TC0 , Q1 goes to TC1, Q2 goes to TC2, and Q3 goes to TC3). For more information, refer to Section 10.3.3.

The EDMA3TC receives the request and is responsible for data movement, as specified in the transfer request packet (TRP), other necessary tasks like buffering, and ensuring transfers are carried out in an optimal fashion wherever possible. For more information on EDMA3TC, refer to Section 10.3.1.2.

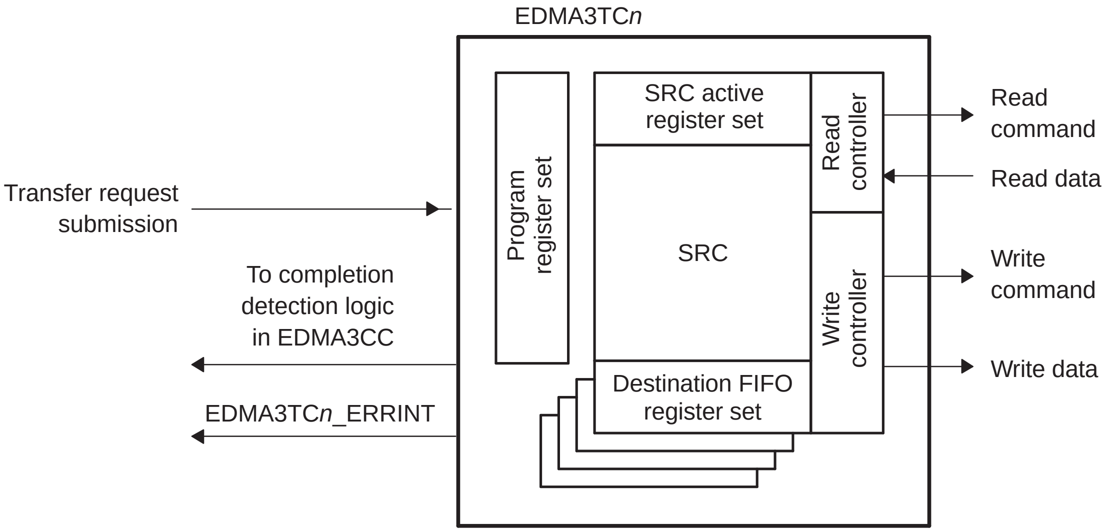
If you have decided to receive an interrupt or to chain to another channel on completion of the current transfer, the EDMA3TC signals completion to the EDMA3CC completion detection logic when the transfer is complete. You can alternately choose to trigger completion when a TR leaves the EDMA3CC boundary, rather than wait for all of the data transfers to complete. Based on the setting of the EDMA3CC interrupt registers, the completion interrupt generation logic is responsible for generating EDMA3CC completion interrupts to the CPU. For more information, refer to Section 10.3.5.

Additionally, the EDMA3CC also has an error detection logic that causes an error interrupt generation on various error conditions (like missed events, exceeding event queue thresholds, etc.). For more information on error interrupts, refer to Section 10.3.9.4.

10.3.1.2 EDMA3 Transfer Controller (EDMA3TC)

Section 10.3.9.4 shows a functional block diagram of the EDMA3 transfer controller (EDMA3TC).

Figure 10-5. EDMA3 Transfer Controller (EDMA3TC) Block Diagram



The main blocks of the EDMA3TC are:

- DMA program register set: The DMA program register set stores the transfer requests received from the EDMA3 channel controller (EDMA3CC).
- DMA source active register set: The DMA source active register set stores the context for the DMA transfer request currently in progress in the read controller.
- Read controller: The read controller issues read commands to the source address.
- Destination FIFO register set: The destination (DST) FIFO register set stores the context for the DMA transfer request(s) currently in progress in the write controller.
- Write controller: The write controller issues write commands/write data to the destination slave.
- Data FIFO: The data FIFO exists for holding temporary in-flight data.
- Completion interface: The completion interface sends completion codes to the EDMA3CC when a transfer completes, and generates interrupts and chained events (also, see Section 10.3.1.1 for more information on transfer completion reporting).

When the EDMA3TC is idle and receives its first TR, DMA program register set receives the TR, where it transitions to the DMA source active set and the destination FIFO register set immediately. The second TR (if pending from EDMA3CC) is loaded into the DMA program set, ensuring it can start as soon as possible when the active transfer completes. As soon as the current active set is exhausted, the TR is loaded from the DMA program register set into the DMA source active register set as well as to the appropriate entry in the destination FIFO register set.

The read controller issues read commands governed by the rules of command fragmentation and optimization. These are issued only when the data FIFO has space available for the data read. When sufficient data is in the data FIFO, the write controller starts issuing a write command again following the rules for command fragmentation and optimization. For more information on command fragmentation and optimization, refer to Section 10.3.12.1.1.

Depending on the number of entries, the read controller can process up to two or four transfer requests ahead of the destination subject to the amount of free data FIFO.

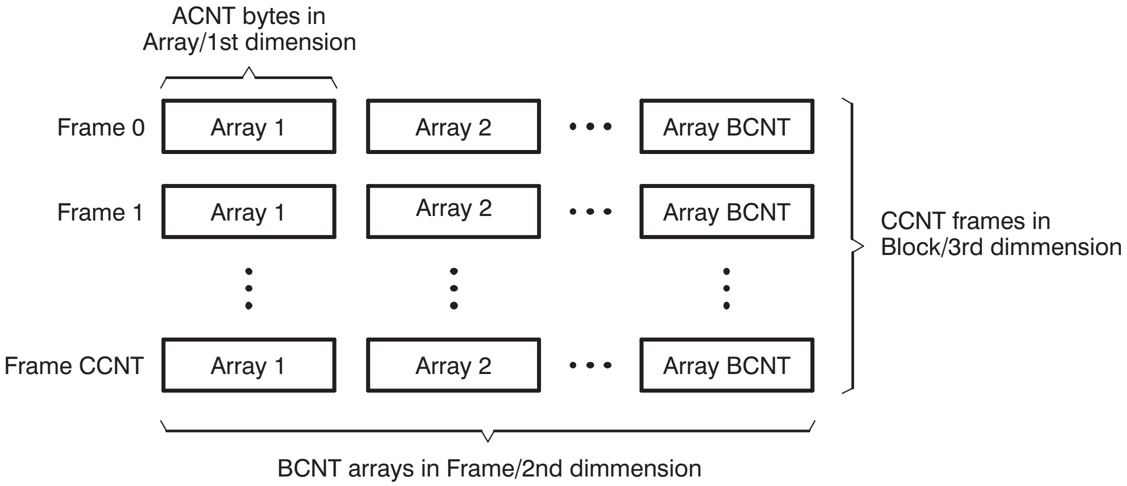
10.3.2 Types of EDMA3 Transfers

An EDMA3 transfer is always defined in terms of three dimensions. Figure 10-6 shows the three dimensions used by EDMA3 transfers. These three dimensions are defined as:

- 1st Dimension or Array (A): The 1st dimension in a transfer consists of ACNT contiguous bytes.
- 2nd Dimension or Frame (B): The 2nd dimension in a transfer consists of BCNT arrays of ACNT bytes. Each array transfer in the 2nd dimension is separated from each other by an index programmed using SRCBIDX or DSTBIDX.
- 3rd Dimension or Block (C): The 3rd dimension in a transfer consists of CCNT frames of BCNT arrays of ACNT bytes. Each transfer in the 3rd dimension is separated from the previous by an index programmed using SRCCIDX or DSTCIDX.

Note that the reference point for the index depends on the synchronization type. The amount of data transferred upon receipt of a trigger/synchronization event is controlled by the synchronization types (SYNCDIM bit in OPT). Of the three dimensions, only two synchronization types are supported: A-synchronized transfers and AB-synchronized transfers.

Figure 10-6. Definition of ACNT, BCNT, and CCNT



10.3.2.1 A-Synchronized Transfers

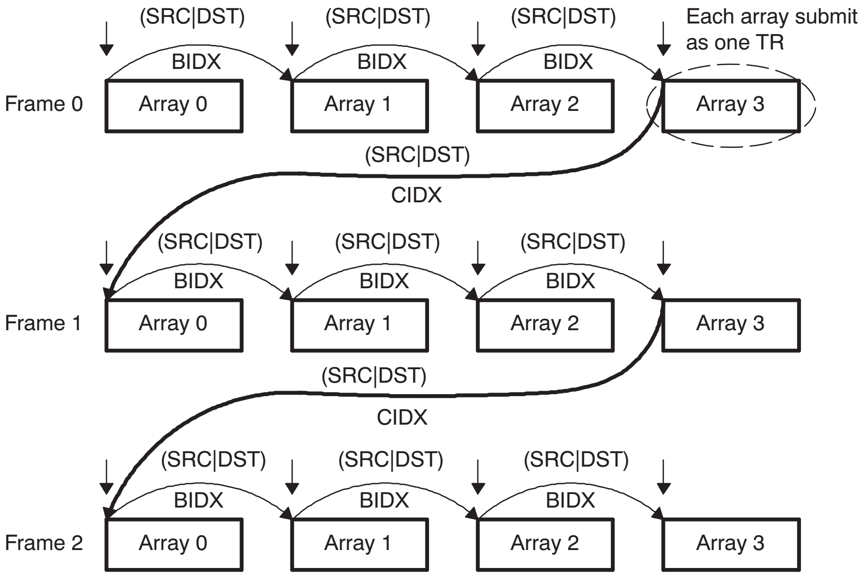
In an A-synchronized transfer, each EDMA3 sync event initiates the transfer of the 1st dimension of ACNT bytes, or one array of ACNT bytes. In other words, each event/TR packet conveys the transfer information for one array only. Thus, BCNT × CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by SRCBIDX and DSTBIDX, as shown in Figure 10-7, where the start address of Array N is equal to the start address of Array N – 1 plus source (SRC) or destination (DST) BIDX.

Frames are always separated by SRCCIDX and DSTCIDX. For A-synchronized transfers, after the frame is exhausted, the address is updated by adding SRCCIDX/DSTCIDX to the beginning address of the last array in the frame. As in Figure 10-7, SRCCIDX/DSTCIDX is the difference between the start of Frame 0 Array 3 to the start of Frame 1 Array 0.

Figure 10-7 shows an A-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of n (ACNT) bytes. In this example, a total of 12 sync events (BCNT × CCNT) exhaust a PaRAM set. See Section 10.3.3.6 for details on parameter set updates.

Figure 10-7. A-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)



10.3.2.2 AB-Synchronized Transfers

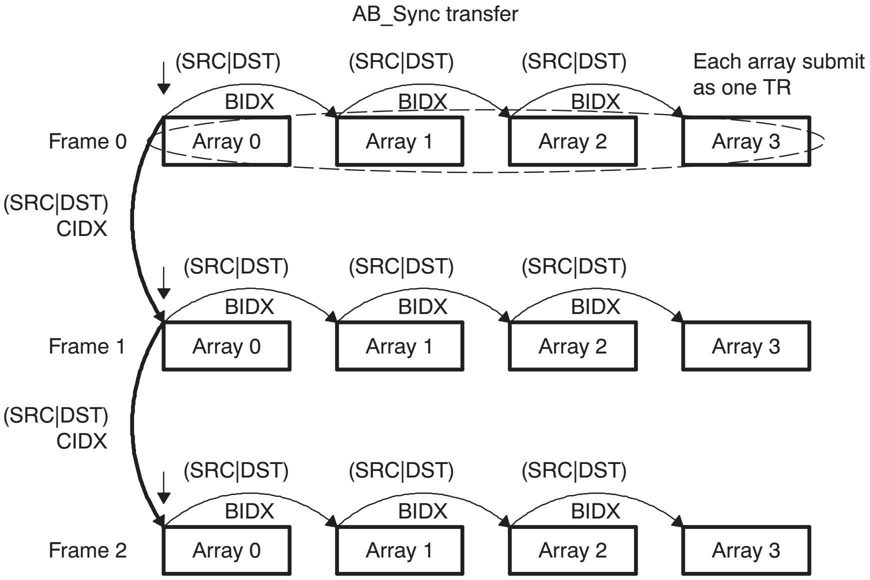
In a AB-synchronized transfer, each EDMA3 sync event initiates the transfer of 2 dimensions or one frame. In other words, each event/TR packet conveys information for one entire frame of BCNT arrays of ACNT bytes. Thus, CCNT events are needed to completely service a PaRAM set.

Arrays are always separated by SRCBIDX and DSTBIDX as shown in Figure 10-8. Frames are always separated by SRCCIDX and DSTCIDX.

Note that for AB-synchronized transfers, after a TR for the frame is submitted, the address update is to add SRCCIDX/DSTCIDX to the beginning address of the beginning array in the frame. This is different from A-synchronized transfers where the address is updated by adding SRCCIDX/DSTCIDX to the start address of the last array in the frame. See Section 10.3.3.6 for details on parameter set updates.

Figure 10-8 shows an AB-synchronized transfer of 3 (CCNT) frames of 4 (BCNT) arrays of *n* (ACNT) bytes. In this example, a total of 3 sync events (CCNT) exhaust a PaRAM set; that is, a total of 3 transfers of 4 arrays each completes the transfer.

Figure 10-8. AB-Synchronized Transfers (ACNT = n, BCNT = 4, CCNT = 3)



NOTE: ABC-synchronized transfers are not directly supported. But can be logically achieved by chaining between multiple AB-synchronized transfers.

10.3.3 Parameter RAM (PaRAM)

The EDMA3 controller is a RAM-based architecture. The transfer context (source/destination addresses, count, indexes, etc.) for DMA or QDMA channels is programmed in a parameter RAM table within EDMA3CC, referred to as PaRAM. The PaRAM table is segmented into multiple PaRAM sets. Each PaRAM set includes eight four-byte PaRAM set entries (32-bytes total per PaRAM set), which includes typical DMA transfer parameters such as source address, destination address, transfer counts, indexes, options, etc.

The PaRAM structure supports flexible ping-pong, circular buffering, channel chaining, and auto-reloading (linking).

The contents of the PaRAM include the following:

- 256 PaRAM sets
- 64 channels that are direct mapped and can be used as link or QDMA sets if not used for DMA channels
- 64 channels remain for link or QDMA sets

By default, all channels map to PaRAM set to 0. These should be remapped before use. For more information, see DCHMAP registers and QCHMAP registers.

Table 10-5. EDMA3 Parameter RAM Contents

PaRAM Set Number	Address	Parameters
0	EDMA Base Address + 4000h to EDMA Base Address + 401Fh	PaRAM set 0
1	EDMA Base Address + 4020h to EDMA Base Address + 403Fh	PaRAM set 1
2	EDMA Base Address + 4040h to EDMA Base Address + 405Fh	PaRAM set 2
3	EDMA Base Address + 4060h to EDMA Base Address + 407Fh	PaRAM set 3
4	EDMA Base Address + 4080h to EDMA Base Address + 409Fh	PaRAM set 4
5	EDMA Base Address + 40A0h to EDMA Base Address + 40BFh	PaRAM set 5
6	EDMA Base Address + 40C0h to EDMA Base Address + 40DFh	PaRAM set 6
7	EDMA Base Address + 40E0h to EDMA Base Address + 40FFh	PaRAM set 7
8	EDMA Base Address + 4100h to EDMA Base Address + 411Fh	PaRAM set 8
9	EDMA Base Address + 4120h to EDMA Base Address + 413Fh	PaRAM set 9
...	...	...
63	EDMA Base Address + 47E0h to EDMA Base Address + 47FFh	PaRAM set 63
64	EDMA Base Address + 4800h to EDMA Base Address + 481Fh	PaRAM set 64
65	EDMA Base Address + 4820h to EDMA Base Address + 483Fh	PaRAM set 65
...	...	...
254	EDMA Base Address + 5FC0h to EDMA Base Address + 5FDFh	PaRAM set 254
255	EDMA Base Address + 5FE0h to EDMA Base Address + 5FFFh	PaRAM set 255

10.3.3.1 PaRAM

Each parameter set of PaRAM is organized into eight 32-bit words or 32 bytes, as shown in Figure 10-9 and described in Table 10-6. Each PaRAM set consists of 16-bit and 32-bit parameters.

Figure 10-9. PaRAM Set

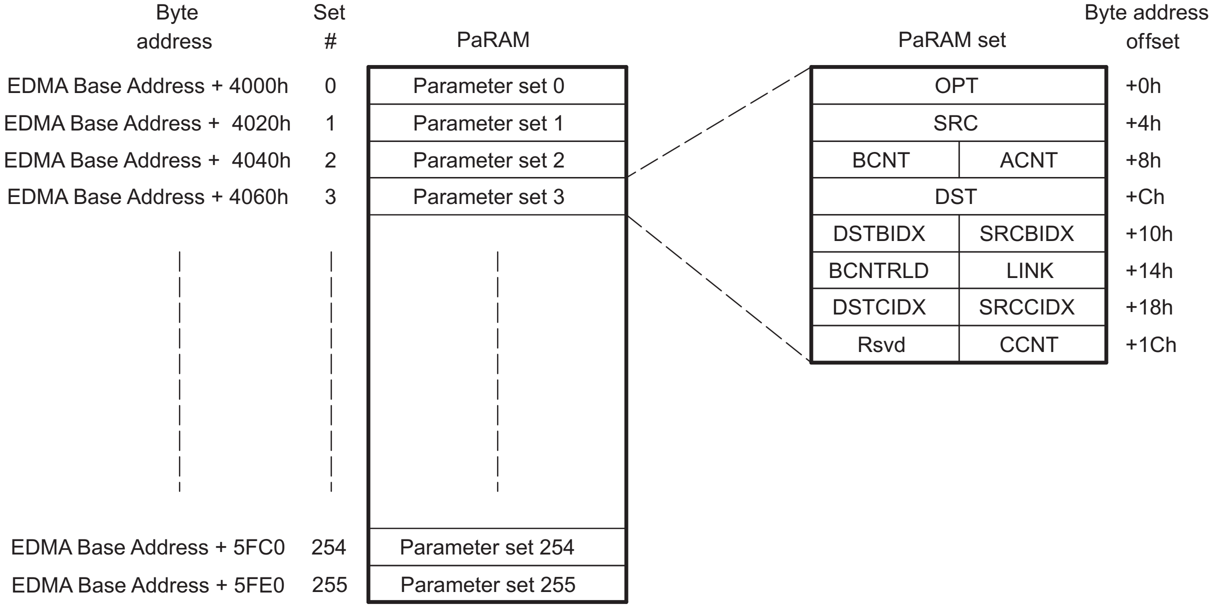


Table 10-6. EDMA3 Channel Parameter Description

Offset Address (bytes)	Acronym	Parameter	Description
0h	OPT	Channel Options	Transfer configuration options
4h	SRC	Channel Source Address	The byte address from which data is transferred
8h(1)	ACNT	Count for 1st Dimension	Unsigned value specifying the number of contiguous bytes within an array (first dimension of the transfer). Valid values range from 1 to 65 535.
	BCNT	Count for 2nd Dimension	Unsigned value specifying the number of arrays in a frame, where an array is ACNT bytes. Valid values range from 1 to 65 535.
Ch	DST	Channel Destination Address	The byte address to which data is transferred
10h(1)	SRCBIDX	Source BCNT Index	Signed value specifying the byte address offset between source arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
	DSTBIDX	Destination BCNT Index	Signed value specifying the byte address offset between destination arrays within a frame (2nd dimension). Valid values range from –32 768 and 32 767.
14h(1)	LINK	Link Address	The PaRAM address containing the PaRAM set to be linked (copied from) when the current PaRAM set is exhausted. A value of FFFFh specifies a null link.
	BCNTRLD	BCNT Reload	The count value used to reload BCNT when BCNT decrements to 0 (TR is submitted for the last array in 2nd dimension). Only relevant in A-synchronized transfers.
18h(1)	SRCCIDX	Source CCNT Index	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last source array in a frame to the beginning of the first source array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first source array in a frame to the beginning of the first source array in the next frame.
	DSTCIDX	Destination CCNT index	Signed value specifying the byte address offset between frames within a block (3rd dimension). Valid values range from –32 768 and 32 767. A-synchronized transfers: The byte address offset from the beginning of the last destination array in a frame to the beginning of the first destination array in the next frame. AB-synchronized transfers: The byte address offset from the beginning of the first destination array in a frame to the beginning of the first destination array in the next frame.
1Ch	CCNT	Count for 3rd Dimension	Unsigned value specifying the number of frames in a block, where a frame is BCNT arrays of ACNT bytes. Valid values range from 1 to 65 535.
	RSVD	Reserved	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

(1) If OPT, SRC, or DST is the trigger word for a QDMA transfer, then doing a 32-bit access is required for that field. TI also recommends performing only 32-bit accesses on the parameter RAM for best code compatibility. For example, switching the endianness of the processor swaps addresses of the 16-bit fields, but 32-bit accesses avoid the issue entirely.

10.3.3.2 EDMA3 Channel PaRAM Set Entry Fields

10.3.3.2.1 Channel Options Parameter (OPT)

The channel options parameter (OPT) is shown in Figure 10-10 and described in Table 10-7.

Figure 10-10. Channel Options Parameter (OPT)

31	30 28	27 24	23	22	21	20	19 18	17 16
PRIV	Reserved	PRIVID	ITCCHEN	TCCHEN	ITCINTEN	TCINTEN	Reserved	TCC
R-0	R-0	R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

15 12	11	10 8	7 4	3	2	1	0
TCC	TCCMODE	FWID	Reserved	STATIC	SYNCDIM	DAM	SAM
R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

Table 10-7. Channel Options Parameters (OPT) Field Descriptions

Bit	Field	Value	Description
31	PRIV		Privilege level (supervisor versus user) for the host/CPU/DMA that programmed this PaRAM set. This value is set with the EDMA3 master's privilege value when any part of the PaRAM set is written.
		0	User level privilege.
		1	Supervisor level privilege.
30-28	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
27-24	PRIVID	0-Fh	Privilege identification for the external host/CPU/DMA that programmed this PaRAM set. This value is set with the EDMA3 master's privilege identification value when any part of the PaRAM set is written.
23	ITCCHEN		Intermediate transfer completion chaining enable.
		0	Intermediate transfer complete chaining is disabled.
		1	Intermediate transfer complete chaining is enabled.
			When enabled, the chained event register (CER/CERH) bit is set on every intermediate chained transfer completion (upon completion of every intermediate TR in the PaRAM set, except the final TR in the PaRAM set). The bit (position) set in CER or CERH is the TCC value specified.
22	TCCHEN		Transfer complete chaining enable.
		0	Transfer complete chaining is disabled.
		1	Transfer complete chaining is enabled.
			When enabled, the chained event register (CER/CERH) bit is set on final chained transfer completion (upon completion of the final TR in the PaRAM set). The bit (position) set in CER or CERH is the TCC value specified.
21	ITCINTEN		Intermediate transfer completion interrupt enable.
		0	Intermediate transfer complete interrupt is disabled.
		1	Intermediate transfer complete interrupt is enabled.
			When enabled, the interrupt pending register (IPR / IPRH) bit is set on every intermediate transfer completion (upon completion of every intermediate TR in the PaRAM set, except the final TR in the PaRAM set). The bit (position) set in IPR or IPRH is the TCC value specified. To generate a completion interrupt to the CPU, the corresponding IER [TCC] / IERH [TCC] bit must be set.
20	TCINTEN		Transfer complete interrupt enable.
		0	Transfer complete interrupt is disabled.
		1	Transfer complete interrupt is enabled.
			When enabled, the interrupt pending register (IPR / IPRH) bit is set on transfer completion (upon completion of the final TR in the PaRAM set). The bit (position) set in IPR or IPRH is the TCC value specified. To generate a completion interrupt to the CPU, the corresponding IER[TCC] / IERH [TCC] bit must be set.
19-18	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.

Table 10-7. Channel Options Parameters (OPT) Field Descriptions (continued)

Bit	Field	Value	Description
17-12	TCC	0-3Fh	Transfer complete code. This 6-bit code sets the relevant bit in the chaining enable register (CER [TCC] /CERH [TCC]) for chaining or in the interrupt pending register (IPR [TCC] / IPRH [TCC]) for interrupts.
11	TCCMODE		Transfer complete code mode. Indicates the point at which a transfer is considered completed for chaining and interrupt generation.
		0	Normal completion: A transfer is considered completed after the data has been transferred.
		1	Early completion: A transfer is considered completed after the EDMA3CC submits a TR to the EDMA3TC. TC may still be transferring data when the interrupt/chain is triggered.
10-8	FWID	0-7h	FIFO Width. Applies if either SAM or DAM is set to constant addressing mode.
		0	FIFO width is 8-bit.
		1h	FIFO width is 16-bit.
		2h	FIFO width is 32-bit.
		3h	FIFO width is 64-bit.
		4h	FIFO width is 128-bit.
		5h	FIFO width is 256-bit.
		6h-7h	Reserved.
7-4	Reserved	0	Reserved. Always write 0 to this bit; writes of 1 to this bit are not supported and attempts to do so may result in undefined behavior.
3	STATIC		Static set.
		0	Set is not static. The PaRAM set is updated or linked after a TR is submitted. A value of 0 should be used for DMA channels and for non-final transfers in a linked list of QDMA transfers.
		1	Set is static. The PaRAM set is not updated or linked after a TR is submitted. A value of 1 should be used for isolated QDMA transfers or for the final transfer in a linked list of QDMA transfers.
2	SYNCDIM		Transfer synchronization dimension.
		0	A-synchronized. Each event triggers the transfer of a single array of ACNT bytes.
		1	AB-synchronized. Each event triggers the transfer of BCNT arrays of ACNT bytes.
1	DAM		Destination address mode.
		0	Increment (INCR) mode. Destination addressing within an array increments. Destination is not a FIFO.
		1	Constant addressing (CONST) mode. Destination addressing within an array wraps around upon reaching FIFO width.
0	SAM		Source address mode.
		0	Increment (INCR) mode. Source addressing within an array increments. Source is not a FIFO.
		1	Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width.

10.3.3.2.2 Channel Source Address (SRC)

The 32-bit source address parameter specifies the starting byte address of the source. For SAM in increment mode, there are no alignment restrictions imposed by EDMA3. For SAM in constant addressing mode, you must program the source address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). The EDMA3TC will signal an error, if this rule is violated. See Section 10.3.12.3 for additional details.

10.3.3.2.3 Channel Destination Address (DST)

The 32-bit destination address parameter specifies the starting byte address of the destination. For DAM in increment mode, there are no alignment restrictions imposed by EDMA3. For DAM in constant addressing mode, you must program the destination address to be aligned to a 256-bit aligned address (5 LSBs of address must be 0). The EDMA3TC will signal an error, if this rule is violated. See Section 10.3.12.3 for additional details.

10.3.3.2.4 Count for 1st Dimension (ACNT)

ACNT represents the number of bytes within the 1st dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65 535. Therefore, the maximum number of bytes in an array is 65 535 bytes (64K – 1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to EDMA3TC. A transfer with ACNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in OPT.

See Section 10.3.3.5 and Section 10.3.5.3 for details on dummy/null completion conditions.

10.3.3.2.5 Count for 2nd Dimension (BCNT)

BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT are between 1 and 65 535. Therefore, the maximum number of arrays in a frame is 65 535 (64K – 1 arrays). A transfer with BCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in OPT.

See Section 10.3.3.5 and Section 10.3.5.3 for details on dummy/null completion conditions.

10.3.3.2.6 Count for 3rd Dimension (CCNT)

CCNT is a 16-bit unsigned value that specifies the number of frames in a block. Valid values for CCNT are between 1 and 65 535. Therefore, the maximum number of frames in a block is 65 535 (64K – 1 frames). A transfer with CCNT equal to 0 is considered either a null or dummy transfer. A dummy or null transfer generates a completion code depending on the settings of the completion bit fields in OPT.

A CCNT value of 0 is considered either a null or dummy transfer. See Section 10.3.3.5 and Section 10.3.5.3 for details on dummy/null completion conditions.

10.3.3.2.7 BCNT Reload (BCNTRLD)

BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-synchronized transfers. In this case, the EDMA3CC decrements the BCNT value by 1 on each TR submission. When BCNT reaches 0, the EDMA3CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value.

For AB-synchronized transfers, the EDMA3CC submits the BCNT in the TR and the EDMA3TC decrements BCNT appropriately. For AB-synchronized transfers, BCNTRLD is not used.

10.3.3.2.8 Source B Index (SRCBIDX)

SRCBIDX is a 16-bit signed value (2s complement) used for source address modification between each array in the 2nd dimension. Valid values for SRCBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the source array to the beginning of the next source array. It applies to both A-synchronized and AB-synchronized transfers. Some examples:

- SRCBIDX = 0000h (0): no address offset from the beginning of an array to the beginning of the next array. All arrays are fixed to the same beginning address.
- SRCBIDX = 0003h (+3): the address offset from the beginning of an array to the beginning of the next array in a frame is 3 bytes. For example, if the current array begins at address 1000h, the next array begins at 1003h.
- SRCBIDX = FFFFh (–1): the address offset from the beginning of an array to the beginning of the next array in a frame is –1 byte. For example, if the current array begins at address 5054h, the next array begins at 5053h.

10.3.3.2.9 Destination B Index (DSTBIDX)

DSTBIDX is a 16-bit signed value (2s complement) used for destination address modification between each array in the 2nd dimension. Valid values for DSTBIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the destination array to the beginning of the next destination array within the current frame. It applies to both A-synchronized and AB-synchronized transfers. See SRCBIDX for examples.

10.3.3.2.10 Source C Index (SRCCIDX)

SRCCIDX is a 16-bit signed value (2s complement) used for source address modification in the 3rd dimension. Valid values for SRCCIDX are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by SRC address) to the beginning of the first source array in the next frame. It applies to both A-synchronized and AB-synchronized transfers. Note that when SRCCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 10-7), while the current array in an AB-synchronized transfer is the first array in the frame (Figure 10-8).

10.3.3.2.11 Destination C Index (DSTCIDX)

DSTCIDX is a 16-bit signed value (2s complement) used for destination address modification in the 3rd dimension. Valid values are between –32 768 and 32 767. It provides a byte address offset from the beginning of the current array (pointed to by DST address) to the beginning of the first destination array TR in the next frame. It applies to both A-synchronized and AB-synchronized transfers. Note that when DSTCIDX is applied, the current array in an A-synchronized transfer is the last array in the frame (Figure 10-7), while the current array in a AB-synchronized transfer is the first array in the frame (Figure 10-8).

10.3.3.2.12 Link Address (LINK)

The EDMA3CC provides a mechanism, called linking, to reload the current PaRAM set upon its natural termination (that is, after the count fields are decremented to 0) with a new PaRAM set. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the EDMA3CC loads/reloads the next PaRAM set during linking.

You must program the link address to point to a valid aligned 32-byte PaRAM set. The 5 LSBs of the LINK field should be cleared to 0.

The EDMA3CC ignores the upper 2 bits of the LINK entry, allowing the programmer the flexibility of programming the link address as either an absolute/literal byte address or use the PaRAM-base-relative offset address. Therefore, if you make use of the literal address with a range from 4000h to 7FFFh, it will be treated as a PaRAM-base-relative value of 0000h to 3FFFh.

You should make sure to program the LINK field correctly, so that link update is requested from a PaRAM address that falls in the range of the available PaRAM addresses on the device.

A LINK value of FFFFh is referred to as a NULL link that should cause the EDMA3CC to perform an internal write of 0 to all entries of the current PaRAM set, except for the LINK field that is set to FFFFh. Also, see Section 10.3.5 for details on terminating a transfer.

10.3.3.3 Null PaRAM Set

A null PaRAM set is defined as a PaRAM set where all count fields (ACNT, BCNT, and CCNT) are cleared to 0. If a PaRAM set associated with a channel is a NULL set, then when serviced by the EDMA3CC, the bit corresponding to the channel is set in the associated event missed register (EMR, EMRH, or QEMR). This bit remains set in the associated secondary event register (SER, SERH, or QSER). *This implies that any future events on the same channel are ignored by the EDMA3CC and you are required to clear the bit in SER, SERH, or QSER for the channel.* This is considered an error condition, since events are not expected on a channel that is configured as a null transfer. For more information, see the SER and EMR registers.

10.3.3.4 Dummy PaRAM Set

A dummy PaRAM set is defined as a PaRAM set where at least one of the count fields (ACNT, BCNT, or CCNT) is cleared to 0 and at least one of the count fields is nonzero.

If a PaRAM set associated with a channel is a dummy set, then when serviced by the EDMA3CC, it will not set the bit corresponding to the channel (DMA/QDMA) in the event missed register (EMR, EMRH, or QEMR) and the secondary event register (SER, SERH, or QSER) bit gets cleared similar to a normal transfer. Future events on that channel are serviced. A dummy transfer is a legal transfer of 0 bytes. For more information, see the SER and EMR registers.

10.3.3.5 Dummy Versus Null Transfer Comparison

There are some differences in the way the EDMA3CC logic treats a dummy versus a null transfer request. A null transfer request is an error condition, but a dummy transfer is a legal transfer of 0 bytes. A null transfer causes an error bit (E*n*) in EMR to get set and the E*n* bit in SER remains set, essentially preventing any further transfers on that channel without clearing the associated error registers.

Table 10-8 summarizes the conditions and effects of null and dummy transfer requests.

Table 10-8. Dummy and Null Transfer Request

Feature	Null TR	Dummy TR
EMR/EMRH/QEMR is set	Yes	No
SER/SERH/QSER remains set	Yes	No
Link update (STATIC = 0 in OPT)	Yes	Yes
QER is set	Yes	Yes
IPR/IPRH CER/CERH is set using early completion	Yes	Yes

10.3.3.6 Parameter Set Updates

When a TR is submitted for a given DMA/QDMA channel and its corresponding PaRAM set, the EDMA3CC is responsible for updating the PaRAM set in anticipation of the next trigger event. For events that are not final, this includes address and count updates; for final events, this includes the link update.

The specific PaRAM set entries that are updated depend on the channel’s synchronization type (A-synchronized or B-synchronized) and the current state of the PaRAM set. A B-update refers to the decrementing of BCNT in the case of A-synchronized transfers after the submission of successive TRs. A C-update refers to the decrementing of CCNT in the case of A-synchronized transfers after BCNT TRs for ACNT byte transfers have submitted. For AB-synchronized transfers, a C-update refers to the decrementing of CCNT after submission of every transfer request.

See Table 10-9 for details and conditions on the parameter updates. A link update occurs when the PaRAM set is exhausted, as described in Section 10.3.3.7.

After the TR is read from the PaRAM (and is in process of being submitted to EDMA3TC), the following fields are updated if needed:

- A-synchronized: BCNT, CCNT, SRC, DST.
- AB-synchronized: CCNT, SRC, DST.

The following fields are not updated (except for during linking, where all fields are overwritten by the link PaRAM set):

- A-synchronized: ACNT, BCNTRLD, SRCBIDX, DSTBIDX, SRCCIDX, DSTCIDX, OPT, LINK.
- AB-synchronized: ACNT, BCNT, BCNTRLD, SRCBIDX, DSTBIDX, SRCCIDX, DSTCIDX, OPT, LINK.

Note that PaRAM updates only pertain to the information that is needed to properly submit the next transfer request to the EDMA3TC. Updates that occur while data is moved within a transfer request are tracked within the transfer controller, and is detailed in Section 10.3.12. For A-synchronized transfers, the EDMA3CC always submits a TRP for ACNT bytes (BCNT = 1 and CCNT = 1). For AB-synchronized transfers, the EDMA3CC always submits a TRP for ACNT bytes of BCNT arrays (CCNT = 1). The EDMA3TC is responsible for updating source and destination addresses within the array based on ACNT and FWID (in OPT). For AB-synchronized transfers, the EDMA3TC is also responsible to update source and destination addresses between arrays based on SRCBIDX and DSTBIDX.

Table 10-9 shows the details of parameter updates that occur within EDMA3CC for A-synchronized and AB-synchronized transfers.

Table 10-9. Parameter Updates in EDMA3CC (for Non-Null, Non-Dummy PaRAM Set)

	A-Synchronized Transfer			AB-Synchronized Transfer		
	B-Update	C-Update	Link Update	B-Update	C-Update	Link Update
Condition:	**BCNT > 1**	**BCNT == 1 && CCNT > 1**	**BCNT == 1 && CCNT == 1**	**N/A**	**CCNT > 1**	**CCNT == 1**
SRC	+= SRCBIDX	+= SRCCIDX	= Link.SRC	in EDMA3TC	+= SRCCIDX	= Link.SRC
DST	+= DSTBIDX	+= DSTCIDX	= Link.DST	in EDMA3TC	+= DSTCIDX	= Link.DST
ACNT	None	None	= Link.ACNT	None	None	= Link.ACNT
BCNT	–= 1	= BCNTRLD	= Link.BCNT	in EDMA3TC	N/A	= Link.BCNT
CCNT	None	–= 1	= Link.CCNT	in EDMA3TC	–=1	= Link.CCNT
SRCBIDX	None	None	= Link.SRCBIDX	in EDMA3TC	None	= Link.SRCBIDX
DSTBIDX	None	None	= Link.DSTBIDX	None	None	= Link.DSTBIDX
SRCCIDX	None	None	= Link.SRCBIDX	in EDMA3TC	None	= Link.SRCBIDX
DSTCIDX	None	None	= Link.DSTBIDX	None	None	= Link.DSTBIDX
LINK	None	None	= Link.LINK	None	None	= Link.LINK
BCNTRLD	None	None	= Link.BCNTRLD	None	None	= Link.BCNTRLD
OPT(1)	None	None	= LINK.OPT	None	None	= LINK.OPT

(1) In all cases, no updates occur if OPT.STATIC == 1 for the current PaRAM set.

NOTE: The EDMA3CC includes no special hardware to detect when an indexed address update calculation overflows/underflows. The address update will wrap across boundaries as programmed by the user. You should ensure that no transfer is allowed to cross internal port boundaries between peripherals. A single TR must target a single source/destination slave endpoint.

10.3.3.7 Linking Transfers

The EDMA3CC provides a mechanism known as linking, which allows the entire PaRAM set to be reloaded from a location within the PaRAM memory map (for both DMA and QDMA channels). Linking is especially useful for maintaining ping-pong buffers, circular buffering, and repetitive/continuous transfers with no CPU intervention. Upon completion of a transfer, the current transfer parameters are reloaded with the parameter set pointed that the 16-bit link address field of the current parameter set points to. Linking only occurs when the STATIC bit in OPT is cleared.

NOTE: You should always link a transfer (EDMA3 or QDMA) to another useful transfer. If you must terminate a transfer, then you should link the transfer to a NULL parameter set. See Section 10.3.3.3.

The link update occurs after the current PaRAM set event parameters have been exhausted. An event's parameters are exhausted when the EDMA3 channel controller has submitted all of the transfers that are associated with the PaRAM set.

A link update occurs for null and dummy transfers depending on the state of the STATIC bit in OPT and the LINK field. In both cases (null or dummy), if the value of LINK is FFFFh, then a null PaRAM set (with all 0s and LINK set to FFFFh) is written to the current PaRAM set. Similarly, if LINK is set to a value other than FFFFh, then the appropriate PaRAM location that LINK points to is copied to the current PaRAM set.

Once the channel completion conditions are met for an event, the transfer parameters that are located at the link address are loaded into the current DMA or QDMA channel’s associated parameter set. This indicates that the EDMA3CC reads the entire set (eight words) from the PaRAM set specified by LINK and writes all eight words to the PaRAM set that is associated with the current channel. Figure 10-11 shows an example of a linked transfer.

Any PaRAM set in the PaRAM can be used as a link/reload parameter set. The PaRAM sets associated with peripheral synchronization events (see Section 10.3.6) should only be used for linking if the corresponding events are disabled.

If a PaRAM set location is defined as a QDMA channel PaRAM set (by QCHMAP*n*), then copying the link PaRAM set into the current QDMA channel PaRAM set is recognized as a trigger event. It is latched in QER because a write to the trigger word was performed. You can use this feature to create a linked list of transfers using a single QDMA channel and multiple PaRAM sets. See Section 10.3.4.2.

Linking to itself replicates the behavior of auto-initialization, thus facilitating the use of circular buffering and repetitive transfers. After an EDMA3 channel exhausts its current PaRAM set, it reloads all of the parameter set entries from another PaRAM set, which is initialized with values that are identical to the original PaRAM set. Figure 10-11 shows an example of a linked to self transfer. Here, the PaRAM set 255 has the link field pointing to the address of parameter set 255 (linked to self).

NOTE: If the STATIC bit in OPT is set for a PaRAM set, then link updates are not performed.

10.3.3.8 Constant Addressing Mode Transfers/Alignment Issues

If either SAM or DAM is set (constant addressing mode), then the source or destination address must be aligned to a 256-bit aligned address, respectively, and the corresponding BIDX should be an even multiple of 32 bytes (256 bits). The EDMA3CC does not recognize errors here, but the EDMA3TC asserts an error if this is not true. See Section 10.3.12.3.

NOTE: The constant addressing (CONST) mode has limited applicability. The EDMA3 should be configured for the constant addressing mode (SAM/DAM = 1) only if the transfer source or destination (on-chip memory, off-chip memory controllers, slave peripherals) support the constant addressing mode. See the device-specific data manual or chapter in this TRM to verify if the constant addressing mode is supported. If the constant addressing mode is not supported, the similar logical transfer can be achieved using the increment (INCR) mode (SAM/DAM =0) by appropriately programming the count and indices values.

10.3.3.9 Element Size

The EDMA3 controller does not use element-size and element-indexing. Instead, all transfers are defined in terms of all three dimensions: ACNT, BCNT, and CCNT. An element-indexed transfer is logically achieved by programming ACNT to the size of the element and BCNT to the number of elements that need to be transferred. For example, if you have 16-bit audio data and 256 audio samples that must be transferred to a serial port, you can only do this by programming the ACNT = 2 (2 bytes) and BCNT = 256.

Figure 10-11. Linked Transfer

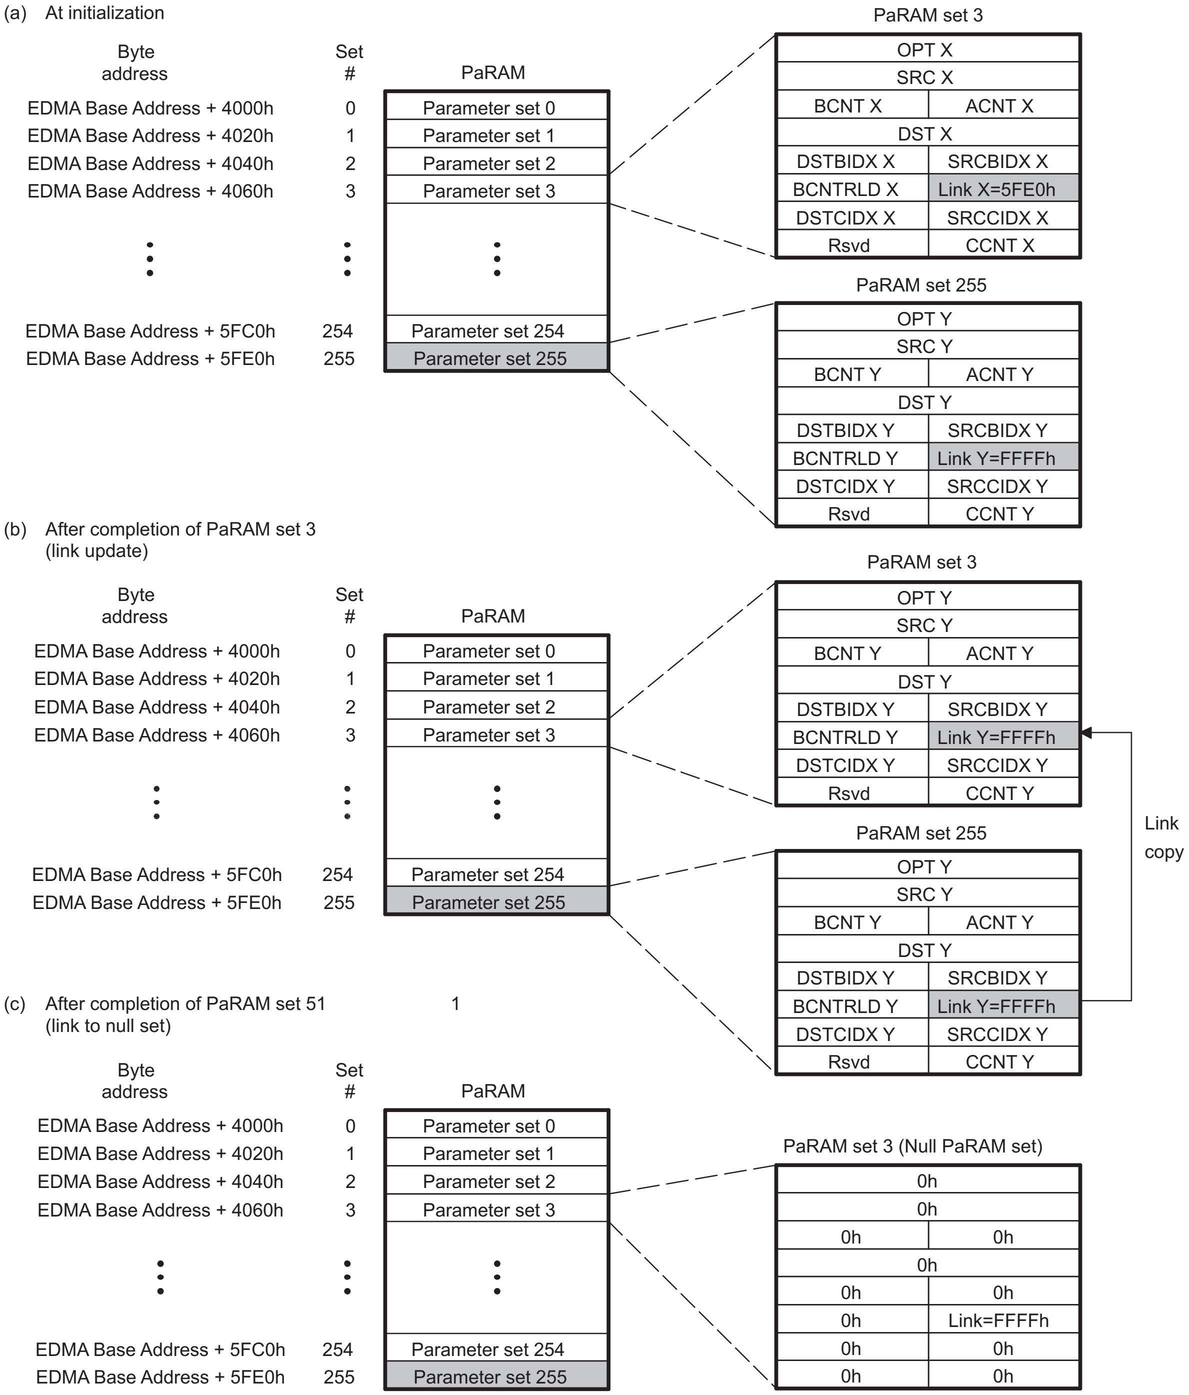

Figure 10-12. Link-to-Self Transfer

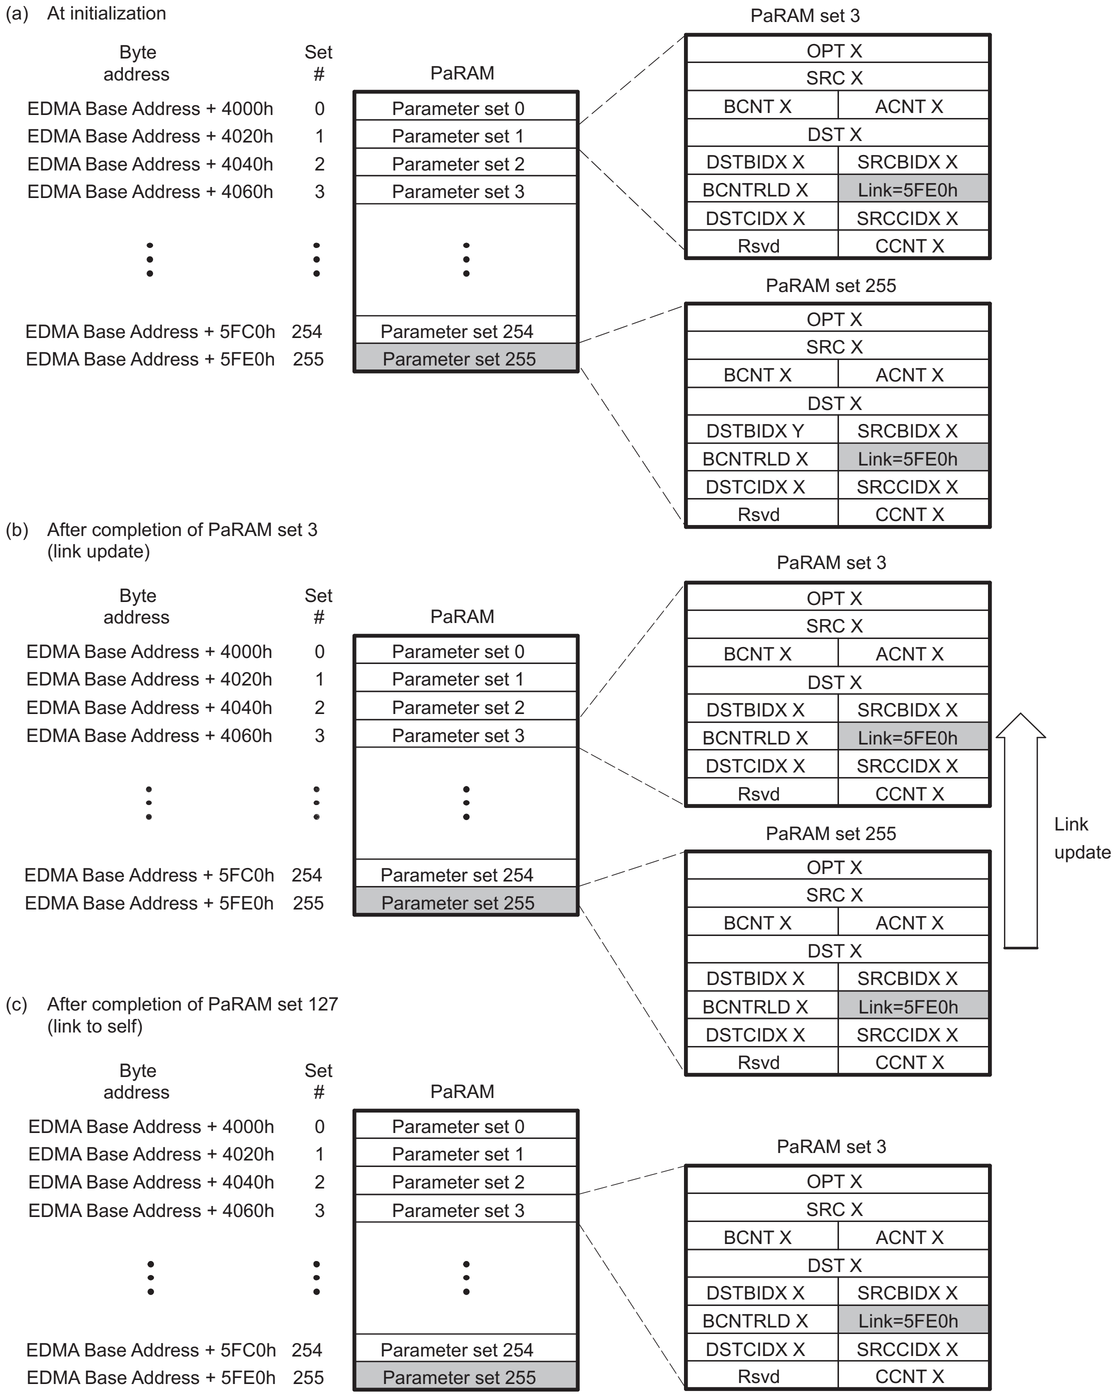


10.3.4 Initiating a DMA Transfer

There are multiple ways to initiate a programmed data transfer using the EDMA3 channel controller. Transfers on DMA channels are initiated by three sources.

They are listed as follows:

- **Event-triggered transfer request** (this is the more typical usage of EDMA3): A peripheral, system, or externally-generated event triggers a transfer request.
- **Manually-triggered transfer request:**The CPU to manually triggers a transfer by writing a 1 to the

corresponding bit in the event set register (ESR/ESRH).

- **Chain-triggered transfer request:** A transfer is triggered on the completion of another transfer or sub-transfer.

Transfers on QDMA channels are initiated by two sources. They are as follows:

- **Auto-triggered transfer request:** Writing to the programmed trigger word triggers a transfer.
- **Link-triggered transfer requests:** Writing to the trigger word triggers the transfer when linking occurs.

10.3.4.1 DMA Channel

10.3.4.1.1 Event-Triggered Transfer Request

When an event is asserted from a peripheral or device pins, it gets latched in the corresponding bit of the event register (ER.E*n* = 1). If the corresponding event in the event enable register (EER) is enabled (EER.E*n* = 1), then the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

If the PaRAM set is valid (not a NULL set), then a transfer request packet (TRP) is submitted to the EDMA3TC and the E*n* bit in ER is cleared. At this point, a new event can be safely received by the EDMA3CC.

If the PaRAM set associated with the channel is a NULL set (see Section 10.3.3.3), then no transfer request (TR) is submitted and the corresponding E*n* bit in ER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EMR.E*n* = 1) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include cleaning the event missed error before re-triggering the DMA channel.

When an event is received, the corresponding event bit in the event register is set (ER.E*n* = 1), regardless of the state of EER.E*n*. If the event is disabled when an external event is received (ER.E*n* = 1 and EER.E*n* = 0), the ER.E*n* bit remains set. If the event is subsequently enabled (EER.E*n* = 1), then the pending event is processed by the EDMA3CC and the TR is processed/submitted, after which the ER.E*n* bit is cleared.

If an event is being processed (prioritized or is in the event queue) and another sync event is received for the same channel prior to the original being cleared (ER.E*n* != 0), then the second event is registered as a missed event in the corresponding bit of the event missed register (EMR.E*n* = 1).

See Section 7.2.2, *EDMA Event Multiplexing*, for a description of how DMA events map to the EDMA event crossbar. See Section 10.3.20, *EDMA Events*, for a table of direct and crossbar mapped EDMA events.

10.3.4.1.2 Manually Triggered Transfer Request

The CPU or any EDMA programmer initiates a DMA transfer by writing to the event set register (ESR). Writing a 1 to an event bit in the ESR results in the event being prioritized/queued in the appropriate event queue, regardless of the state of the EER.E*n* bit. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 10.3.3.3), then no transfer request (TR) is submitted and the corresponding E*n* bit in ER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EMR.E*n* = 1) to indicate that the event was discarded due to a null TR being serviced. Good programming practices should include clearing the event missed error before re-triggering the DMA channel.

If an event is being processed (prioritized or is in the event queue) and the same channel is manually set by a write to the corresponding channel bit of the event set register (ESR.E*n* = 1) prior to the original being cleared (ESR.E*n* = 0), then the second event is registered as a missed event in the corresponding bit of the event missed register (EMR.E*n* = 1).

10.3.4.1.3 Chain-Triggered Transfer Request

Chaining is a mechanism by which the completion of one transfer automatically sets the event for another channel. When a chained completion code is detected, the value of which is dictated by the transfer completion code (TCC[5:0] in OPT of the PaRAM set associated with the channel), it results in the corresponding bit in the chained event register (CER) to be set (CER.E[TCC] = 1).

Once a bit is set in CER, the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If the PaRAM set associated with the channel is a NULL set (see Section 10.3.3.3), then no transfer request (TR) is submitted and the corresponding E*n* bit in CER is cleared and simultaneously the corresponding channel bit is set in the event miss register (EMR.E*n* = 1) to indicate that the event was discarded due to a null TR being serviced. In this case, the error condition must be cleared by you before the DMA channel can be re-triggered. Good programming practices might include clearing the event missed error before re-triggering the DMA channel.

If a chaining event is being processed (prioritized or queued) and another chained event is received for the same channel prior to the original being cleared (CER.E*n* != 0), then the second chained event is registered as a missed event in the corresponding channel bit of the event missed register (EMR.E*n* = 1).

NOTE: Chained event registers, event registers, and event set registers operate independently. An event (E*n*) can be triggered by any of the trigger sources (event-triggered, manually-triggered, or chain-triggered).

10.3.4.2 QDMA Channels

10.3.4.2.1 Auto-triggered and Link-Triggered Transfer Request

QDMA-based transfer requests are issued when a QDMA event gets latched in the QDMA event register (QER.E*n* = 1). A bit corresponding to a QDMA channel is set in the QDMA event register (QER) when the following occurs:

- A CPU (or any EDMA3 programmer) write occurs to a PaRAM address that is defined as a QDMA channel trigger word (programmed in the QDMA channel mapping register (QCHMAP*n*)) for the particular QDMA channel and the QDMA channel is enabled via the QDMA event enable register (QEER.E*n* = 1).
- EDMA3CC performs a link update on a PaRAM set address that is configured as a QDMA channel (matches QCHMAP*n* settings) and the corresponding channel is enabled via the QDMA event enable register (QEER.E*n* = 1).

Once a bit is set in QER, the EDMA3CC prioritizes and queues the event in the appropriate event queue. When the event reaches the head of the queue, it is evaluated for submission as a transfer request to the transfer controller.

As in the event-triggered transfers, if the PaRAM set associated with the channel is valid (it is not a null set) then the TR is submitted to the associated EDMA3TC and the channel can be triggered again.

If a bit is already set in QER (QER.E*n* = 1) and a second QDMA event for the same QDMA channel occurs prior to the original being cleared, the second QDMA event gets captured in the QDMA event miss register (QEMR.E*n* = 1).

10.3.4.3 Comparison Between DMA and QDMA Channels

The primary difference between DMA and QDMA channels is the event/channel synchronization. QDMA events are either auto-triggered or link triggered. auto-triggering allows QDMA channels to be triggered by CPUs with a minimum number of linear writes to PaRAM. Link triggering allows a linked list of transfers to be executed, using a single QDMA PaRAM set and multiple link PaRAM sets.

A QDMA transfer is triggered when a CPU (or other EDMA3 programmer) writes to the trigger word of the QDMA channel parameter set (auto-triggered) or when the EDMA3CC performs a link update on a PaRAM set that has been mapped to a QDMA channel (link triggered). Note that for CPU triggered (manually triggered) DMA channels, in addition to writing to the PaRAM set, it is required to write to the event set register (ESR) to kick-off the transfer.

QDMA channels are typically for cases where a single event will accomplish a complete transfer since the CPU (or EDMA3 programmer) must reprogram some portion of the QDMA PaRAM set in order to re-trigger the channel. In other words, QDMA transfers are programmed with BCNT = CCNT = 1 for A-synchronized transfers, and CCNT = 1 for AB-synchronized transfers.

Additionally, since linking is also supported (if STATIC = 0 in OPT) for QDMA transfers, it allows you to initiate a linked list of QDMAs, so when EDMA3CC copies over a link PaRAM set (including the write to the trigger word), the current PaRAM set mapped to the QDMA channel will automatically be recognized as a valid QDMA event and initiate another set of transfers as specified by the linked set.

10.3.5 Completion of a DMA Transfer

A parameter set for a given channel is complete when the required number of transfer requests is submitted (based on receiving the number of synchronization events). The expected number of TRs for a non-null/non-dummy transfer is shown in Table 10-10 for both synchronization types along with state of the PaRAM set prior to the final TR being submitted. When the counts (BCNT and/or CCNT) are this value, the next TR results in a:

- Final chaining or interrupt codes to be sent by the transfer controllers (instead of intermediate).
- Link updates (linking to either null or another valid link set).

Table 10-10. Expected Number of Transfers for Non-Null Transfer

Sync Mode	Counts at time 0	Total # Transfers	Counts prior to final TR
A-synchronized	ACNT BCNT CCNT	(BCNT × CCNT) TRs of ACNT bytes each	BCNT == 1 && CCNT == 1
AB-synchronized	ACNT BCNT CCNT	CCNT TRs for ACNT × BCNT bytes each	CCNT == 1

You must program the PaRAM OPT field with a specific transfer completion code (TCC) along with the other OPT fields (TCCHEN, TCINTEN, ITCCHEN, and ITCINTEN bits) to indicate whether the completion code is to be used for generating a chained event or/and for generating an interrupt upon completion of a transfer.

The specific TCC value (6-bit binary value) programmed dictates which of the 64-bits in the chain event register (CER[TCC]) and/or interrupt pending register (IPR[TCC]) is set.

You can also selectively program whether the transfer controller sends back completion codes on completion of the final transfer request (TR) of a parameter set (TCCHEN or TCINTEN), for all but the final transfer request (TR) of a parameter set (ITCCHEN or ITCINTEN), or for all TRs of a parameter set (both). See Section 10.3.8 for details on chaining (intermediate/final chaining) and Section 10.3.9 for details on intermediate/final interrupt completion.

A completion detection interface exists between the EDMA3 channel controller and transfer controllers. This interface sends back information from the transfer controller to the channel controller to indicate that a specific transfer is completed. Completion of a transfer is used for generating chained events and/or generating interrupts to the CPUs.

All DMA/QDMA PaRAM sets must also specify a link address value. For repetitive transfers such as ping-pong buffers, the link address value should point to another predefined PaRAM set. Alternatively, a non-repetitive transfer should set the link address value to the null link value. The null link value is defined as FFFFh. See Section 10.3.3.7 for more details.

NOTE: Any incoming events that are mapped to a null PaRAM set results in an error condition. The error condition should be cleared before the corresponding channel is used again. See Section 10.3.3.5.

There are three ways the EDMA3CC gets updated/informed about a transfer completion: normal completion, early completion, and dummy/null completion. This applies to both chained events and completion interrupt generation.

10.3.5.1 Normal Completion

In normal completion mode (TCCMODE = 0 in OPT), the transfer or sub-transfer is considered to be complete when the EDMA3 channel controller receives the completion codes from the EDMA3 transfer controller. In this mode, the completion code to the channel controller is posted by the transfer controller after it receives a signal from the destination peripheral. Normal completion is typically used to generate an interrupt to inform the CPU that a set of data is ready for processing.

10.3.5.2 Early Completion

In early completion mode (TCCMODE = 1 in OPT), the transfer is considered to be complete when the EDMA3 channel controller submits the transfer request (TR) to the EDMA3 transfer controller. In this mode, the channel controller generates the completion code internally. Early completion is typically useful for chaining, as it allows subsequent transfers to be chained-triggered while the previous transfer is still in progress within the transfer controller, maximizing the overall throughput of the set of the transfers.

10.3.5.3 Dummy or Null Completion

This is a variation of early completion. Dummy or null completion is associated with a dummy set (Section 10.3.3.4) or null set (Section 10.3.3.3). In both cases, the EDMA3 channel controller does not submit the associated transfer request to the EDMA3 transfer controllers. However, if the set (dummy/null) has the OPT field programmed to return completion code (intermediate/final interrupt/chaining completion), then it will set the appropriate bits in the interrupt pending registers (IPR/IPRH) or chained event register (CER/CERH). The internal early completion path is used by the channel controller to return the completion codes internally (that is, EDMA3CC generates the completion code).

10.3.6 Event, Channel, and PaRAM Mapping

Several of the 64 DMA channels are tied to a specific hardware event, thus allowing events from device peripherals or external hardware to trigger transfers. A DMA channel typically requests a data transfer when it receives its event (apart from manually-triggered, chain-triggered, and other transfers). The amount of data transferred per synchronization event depends on the channel's configuration (ACNT, BCNT, CCNT, etc.) and the synchronization type (A-synchronized or AB-synchronized).

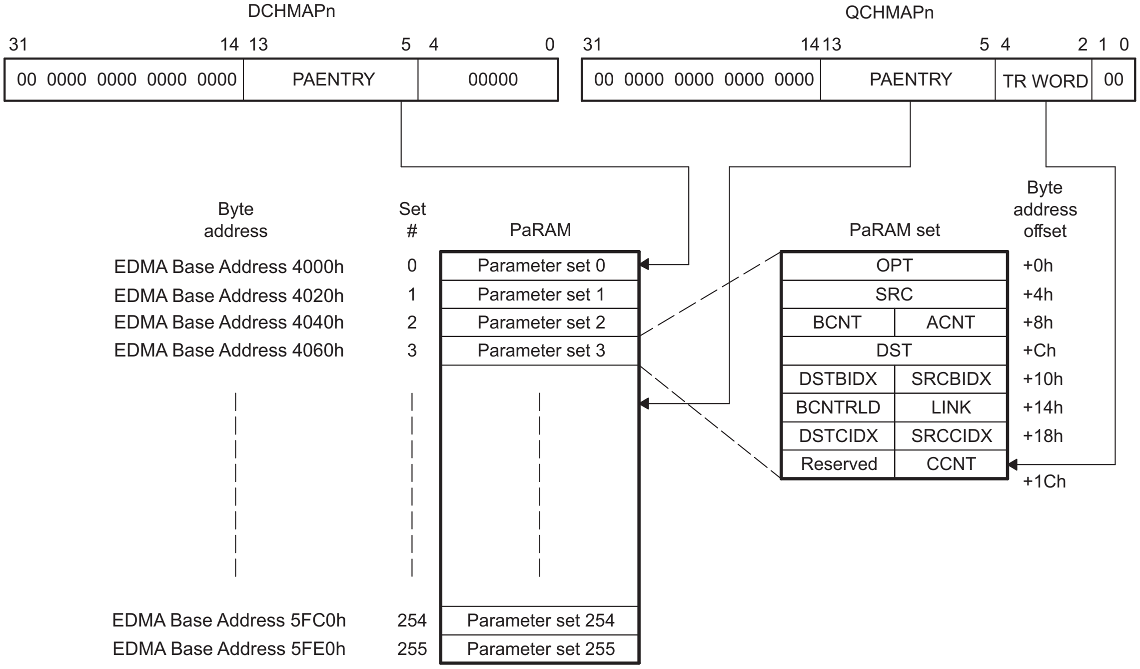
The association of an event to a channel is fixed, each DMA channel has one specific event associated with it. See Section 7.2.2, *EDMA Event Multiplexing*, for a description of how DMA events map to the EDMA event crossbar. See Section 10.3.20, *EDMA Events*, for a table of direct and crossbar mapped EDMA events.

In an application, if a channel does not use the associated synchronization event or if it does not have an associated synchronization event (unused), that channel can be used for manually-triggered or chained-triggered transfers, for linking/reloading, or as a QDMA channel.

10.3.6.1 DMA Channel to PaRAM Mapping

The mapping between the DMA channel numbers and the PaRAM sets is programmable (see Table 10-5). The DMA channel mapping registers (DCHMAPn) in the EDMA3CC provide programmability that allows the DMA channels to be mapped to any of the PaRAM sets in the PaRAM memory map. Figure 10-13 illustrates the use of DCHMAP. There is one DCHMAP register per channel.

Figure 10-13. DMA Channel and QDMA Channel to PaRAM Mapping

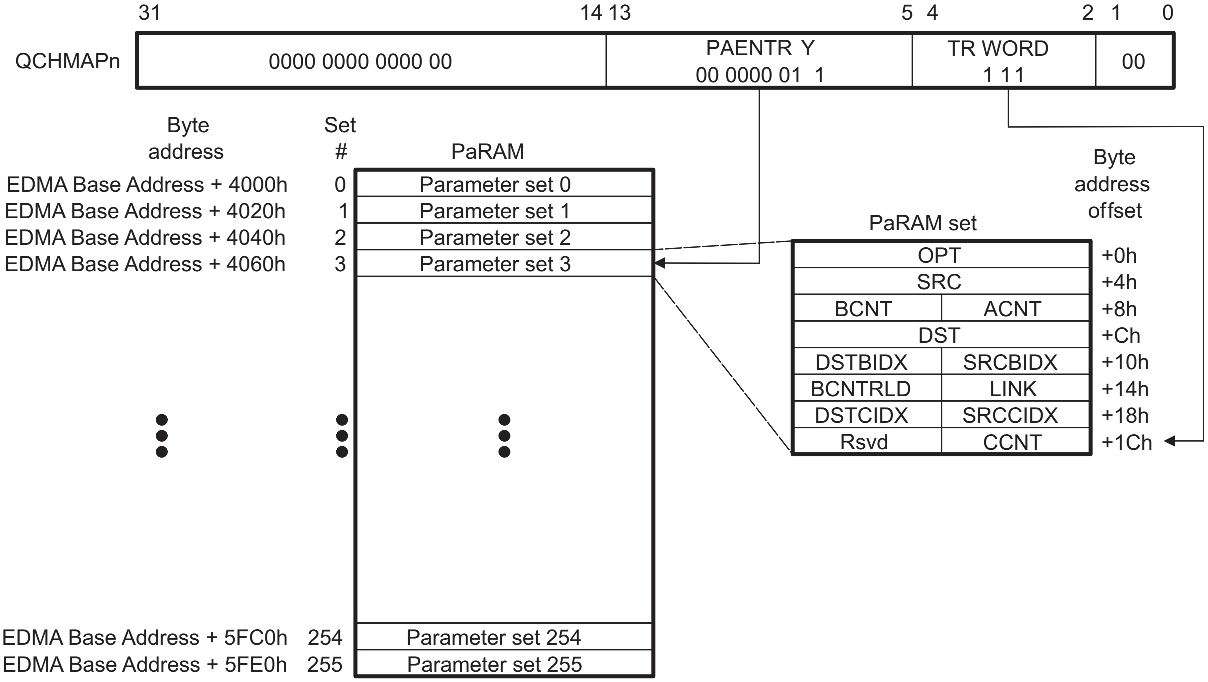


10.3.6.2 QDMA Channel to PaRAM Mapping

The mapping between the QDMA channels and the PaRAM sets is programmable. The QDMA channel mapping register (QCHMAP) in the EDMA3CC allows you to map the QDMA channels to any of the PaRAM sets in the PaRAM memory map. Figure 10-14 illustrates the use of QCHMAP.

Additionally, QCHMAP allows you to program the trigger word in the PaRAM set for the QDMA channel. A trigger word is one of the eight words in the PaRAM set. For a QDMA transfer to occur, a valid TR synchronization event for EDMA3CC is a write to the trigger word in the PaRAM set pointed to by QCHMAP for a particular QDMA channel. By default, QDMA channels are mapped to PaRAM set 0. You must appropriately re-map PaRAM set 0 before you use it.

Figure 10-14. QDMA Channel to PaRAM Mapping



10.3.7 EDMA3 Channel Controller Regions

The EDMA3 channel controller divides its address space into eight regions. Individual channel resources are assigned to a specific region, where each region is typically assigned to a specific EDMA programmer.

You can design the application software to use regions or to ignore them altogether. You can use active memory protection in conjunction with regions so that only a specific EDMA programmer (for example, privilege identification) or privilege level (for example, user vs. supervisor) is allowed access to a given region, and thus to a given DMA or QDMA channel. This allows robust system-level DMA code where each EDMA programmer only modifies the state of the assigned resources. Memory protection is described in Section 10.3.10.

10.3.7.1 Region Overview

The EDMA3 channel controller memory-mapped registers are divided in three main categories:

1. Global registers
2. Global region channel registers
3. Shadow region channel registers

The global registers are located at a single/fixed location in the EDMA3CC memory map. These registers control EDMA3 resource mapping and provide debug visibility and error tracking information.

The channel registers (including DMA, QDMA, and interrupt registers) are accessible via the global channel region address range, or in the shadow *n* channel region address ranges. For example, the event enable register (EER) is visible at the global address of EDMA Base Address + 1020h or region addresses of EDMA Base Address + 2020h for region 0, EDMA Base Address + 2220h for region 1, … EDMA Base Address + 2E20h for region 7.

The DMA region access enable registers (DRAE*m*) and the QDMA region access enable registers (QRAE*n*) control the underlying control register bits that are accessible via the shadow region address space (except for IEVAL*n*). Table 10-11 lists the registers in the shadow region memory map. See the EDMA3CC memory map (Section 10.4) for the complete global memory maps. Figure 10-15 illustrates the conceptual view of the regions.

Table 10-11. Shadow Region Registers

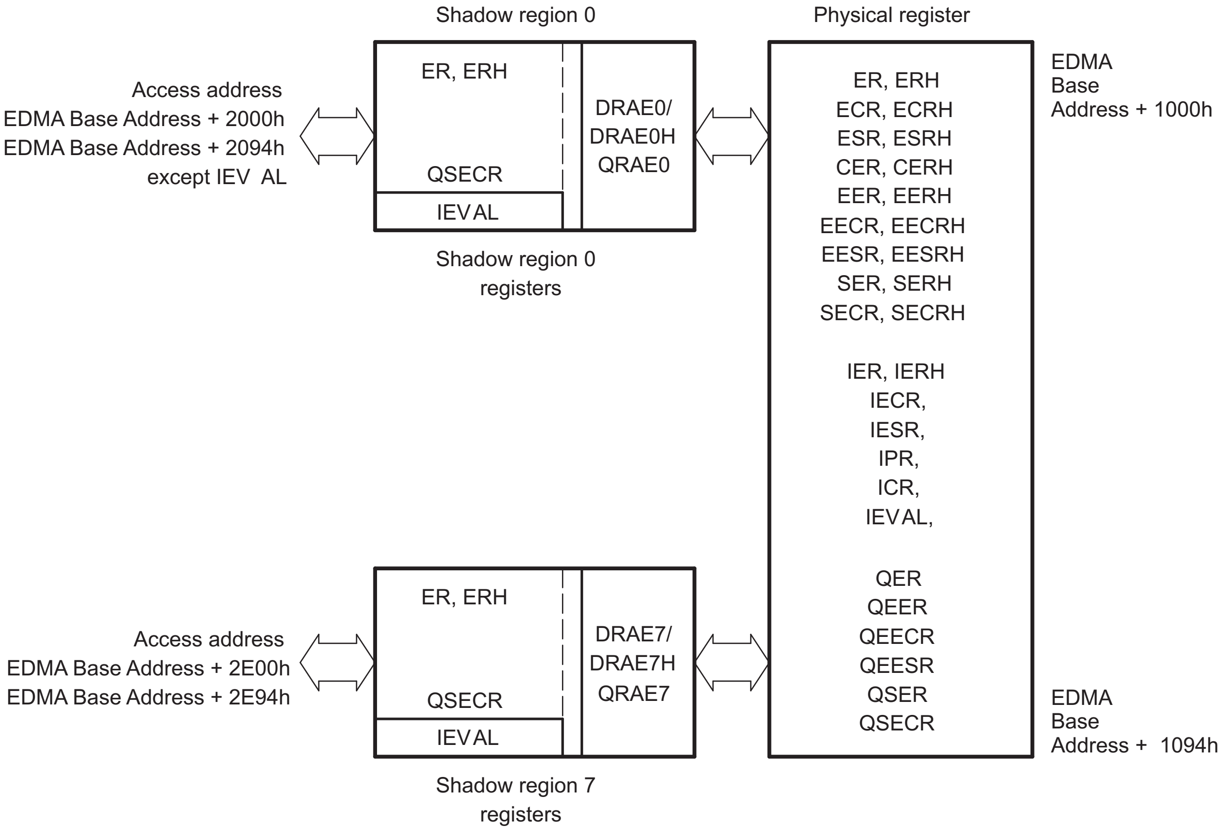
Figure 10-15. Shadow Region Registers



10.3.7.2 Channel Controller Regions

There are eight EDMA3 shadow regions (and associated memory maps). Associated with each shadow region are a set of registers defining which channels and interrupt completion codes belong to that region. These registers are user-programmed per region to assign ownership of the DMA/QDMA channels to a region.

- DRAE*m* and DRAEH*m*: One register pair exists for each of the shadow regions. The number of bits in each register pair matches the number of DMA channels (64 DMA channels). These registers need to be programmed to assign ownership of DMA channels and interrupt (or TCC codes) to the respective region. Accesses to DMA and interrupt registers via the shadow region address view are filtered through the DRAE/DRAEH pair. A value of 1 in the corresponding DRAE(H) bit implies that the corresponding DMA/interrupt channel is accessible; a value of 0 in the corresponding DRAE(H) bit forces writes to be discarded and returns a value of 0 for reads.
- QRAE*n*: One register exists for every region. The number of bits in each register matches the number of QDMA channels (4 QDMA channels). These registers must be programmed to assign ownership of QDMA channels to the respective region. To enable a channel in a shadow region using shadow region 0 QEER, the respective bit in QRAE must be set or writing into QEESR will not have the desired effect.
- MPPA*n* and MPPAG: One register exists for every region. This register defines the privilege level, requestor, and types of accesses allowed to a region's memory-mapped registers.

It is typical for an application to have a unique assignment of QDMA/DMA channels (and, therefore, a given bit position) to a given region.

The use of shadow regions allows for restricted access to EDMA3 resources (DMA channels, QDMA channels, TCC, interrupts) by tasks in a system by setting or clearing bits in the DRAE/ORAE registers. If exclusive access to any given channel / TCC code is required for a region, then only that region's DRAE/ORAE should have the associated bit set.

Example 10-1. Resource Pool Division Across Two Regions

This example illustrates a judicious resource pool division across two regions, assuming region 0 must be allocated 16 DMA channels (0-15) and 1 QDMA channel (0) and 32 TCC codes (0-15 and 48-63). Region 1 needs to be allocated 16 DMA channels (16-32) and the remaining 7 QDMA channels (1-7) and TCC codes (16-47). DRAE should be equal to the OR of the bits that are required for the DMA channels and the TCC codes:

```
Region 0: DRAEH, DRAE = 0xFFFF0000, 0x0000FFFF QRAE = 0x0000001
Region 1: DRAEH, DRAE = 0x0000FFFF, 0xFFFF0000 QRAE = 0x00000FE
```

10.3.7.3 Region Interrupts

In addition to the EDMA3CC global completion interrupt, there is an additional completion interrupt line that is associated with every shadow region. Along with the interrupt enable register (IER), DRAE acts as a secondary interrupt enable for the respective shadow region interrupts. See Section 10.3.9 for more information.

10.3.8 Chaining EDMA3 Channels

The channel chaining capability for the EDMA3 allows the completion of an EDMA3 channel transfer to trigger another EDMA3 channel transfer. The purpose is to allow you the ability to chain several events through one event occurrence.

Chaining is different from linking (Section 10.3.3.7). The EDMA3 link feature reloads the current channel parameter set with the linked parameter set. The EDMA3 chaining feature does not modify or update any channel parameter set; it provides a synchronization event to the chained channel (see Section 10.3.4.1.3 for chain-triggered transfer requests).

Chaining is achieved at either final transfer completion or intermediate transfer completion, or both, of the current channel. Consider a channel *m* (DMA/QDMA) required to chain to channel *n*. Channel number *n* (0-63) needs to be programmed into the TCC bit of channel *m* channel options parameter (OPT) set.

- If final transfer completion chaining (TCCHEN = 1 in OPT) is enabled, the chain-triggered event occurs after the submission of the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If intermediate transfer completion chaining (ITCCHEN = 1 in OPT) is enabled, the chain-triggered event occurs after every transfer request, except the last of channel *m* is either submitted or completed

(depending on early or normal completion).

- If both final and intermediate transfer completion chaining (TCCHEN = 1 and ITCCHEN = 1 in OPT) are enabled, then the chain-trigger event occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 10-12 illustrates the number of chain event triggers occurring in different synchronized scenarios. Consider channel 31 programmed with ACNT = 3, BCNT = 4, CCNT = 5, and TCC = 30.

Table 10-12. Chain Event Triggers

	(Number of chained event triggers on channel 30)	
Options	**A-Synchronized**	**AB-Synchronized**
TCCHEN = 1, ITCCHEN = 0	1 (Owing to the last TR)	1 (Owing to the last TR)
TCCHEN = 0, ITCCHEN = 1	19 (Owing to all but the last TR)	4 (Owing to all but the last TR)
TCCHEN = 1, ITCCHEN = 1	20 (Owing to a total of 20 TRs)	5 (Owing to a total of 5 TRs)

10.3.9 EDMA3 Interrupts

The EDMA3 interrupts are divided into 2 categories: transfer completion interrupts and error interrupts.

There are nine region interrupts, eight shadow regions and one global region. The transfer completion interrupts are listed in Table 10-13. The transfer completion interrupts and the error interrupts from the transfer controllers are all routed to the ARM interrupt controllers.

Table 10-13. EDMA3 Transfer Completion Interrupts

Name	**Description**
EDMA3CC_INT0	EDMA3CC Transfer Completion Interrupt Shadow Region 0
EDMA3CC_INT1	EDMA3CC Transfer Completion Interrupt Shadow Region 1
EDMA3CC_INT2	EDMA3CC Transfer Completion Interrupt Shadow Region 2
EDMA3CC_INT3	EDMA3CC Transfer Completion Interrupt Shadow Region 3
EDMA3CC_INT4	EDMA3CC Transfer Completion Interrupt Shadow Region 4
EDMA3CC_INT5	EDMA3CC Transfer Completion Interrupt Shadow Region 5
EDMA3CC_INT6	EDMA3CC Transfer Completion Interrupt Shadow Region 6
EDMA3CC_INT7	EDMA3CC Transfer Completion Interrupt Shadow Region 7

Table 10-14. EDMA3 Error Interrupts

Name	**Description**
EDMA3CC_ERRINT	EDMA3CC Error Interrupt
EDMA3CC_MPINT	EDMA3CC Memory Protection Interrupt
EDMA3TC0_ERRINT	TC0 Error Interrupt
EDMA3TC1_ERRINT	TC1 Error Interrupt
EDMA3TC2_ERRINT	TC2 Error Interrupt
EDMA3TC3_ERRINT	TC3 Error Interrupt

10.3.9.1 Transfer Completion Interrupts

The EDMA3CC is responsible for generating transfer completion interrupts to the CPUs (and other EDMA3 masters). The EDMA3 generates a single completion interrupt per shadow region, as well as one for the global region on behalf of all 64 channels. The various control registers and bit fields facilitate EDMA3 interrupt generation.

The software architecture should either use the global interrupt or the shadow interrupts, but not both.

The transfer completion code (TCC) value is directly mapped to the bits of the interrupt pending register (IPR/IPRH). For example, if TCC = 10 0001b, IPRH[1] is set after transfer completion, and results in interrupt generation to the CPUs if the completion interrupt is enabled for the CPU. See Section 10.3.9.1.1 for details on enabling EDMA3 transfer completion interrupts.

When a completion code is returned (as a result of early or normal completions), the corresponding bit in IPR/IPRH is set if transfer completion interrupt (final/intermediate) is enabled in the channel options parameter (OPT) for a PaRAM set associated with the transfer.

Table 10-15. Transfer Complete Code (TCC) to EDMA3CC Interrupt Mapping

TCC Bits in OPT (TCINTEN/ITCINTEN = 1)	IPR Bit Set	TCC Bits in OPT (TCINTEN/ITCINTEN = 1)	IPRH Bit Set[1]
0	IPR0	20h	IPR32/IPRH0
1	IPR1	21h	IPR33/IPRH1
2h	IPR2	22h	IPR34/IPRH2
3h	IPR3	23h	IPR35/IPRH3
4h	IPR4	24h	IPR36/IPRH4
...	...	...	...
1Eh	IPR30	3Eh	IPR62/IPRH30
1Fh	IPR31	3Fh	IPR63/IPRH31

[1] Bit fields IPR[32-63] correspond to bits 0 to 31 in IPRH, respectively.

You can program the transfer completion code (TCC) to any value for a DMA/QDMA channel. A direct relation between the channel number and the transfer completion code value does not need to exist. This allows multiple channels having the same transfer completion code value to cause a CPU to execute the same interrupt service routine (ISR) for different channels.

If the channel is used in the context of a shadow region and you intend for the shadow region interrupt to be asserted, then ensure that the bit corresponding to the TCC code is enabled in IER/IERH and in the corresponding shadow region's DMA region access registers (DRAE/DRAEH).

You can enable Interrupt generation at either final transfer completion or intermediate transfer completion, or both. Consider channel *m* as an example.

- If the final transfer interrupt (TCCINT = 1 in OPT) is enabled, the interrupt occurs after the last transfer request of channel *m* is either submitted or completed (depending on early or normal completion).
- If the intermediate transfer interrupt (ITCCINT = 1 in OPT) is enabled, the interrupt occurs after every transfer request, except the last TR of channel *m* is either submitted or completed (depending on early or normal completion).
- If both final and intermediate transfer completion interrupts (TCCINT = 1, and ITCCINT = 1 in OPT) are enabled, then the interrupt occurs after every transfer request is submitted or completed (depending on early or normal completion).

Table 10-16 shows the number of interrupts that occur in different synchronized scenarios. Consider channel 31, programmed with ACNT = 3, BCNT = 4, CCNT = 5, and TCC = 30.

Table 10-16. Number of Interrupts

Options	A-Synchronized	AB-Synchronized
TCINTEN = 1, ITCINTEN = 0	1 (Last TR)	1 (Last TR)
TCINTEN = 0, ITCINTEN = 1	19 (All but the last TR)	4 (All but the last TR)
TCINTEN = 1, ITCINTEN = 1	20 (All TRs)	5 (All TRs)

10.3.9.1.1 Enabling Transfer Completion Interrupts

For the EDMA3 channel controller to assert a transfer completion to the external environment, the interrupts must be enabled in the EDMA3CC. This is in addition to setting up the TCINTEN and ITCINTEN bits in OPT of the associated PaRAM set.

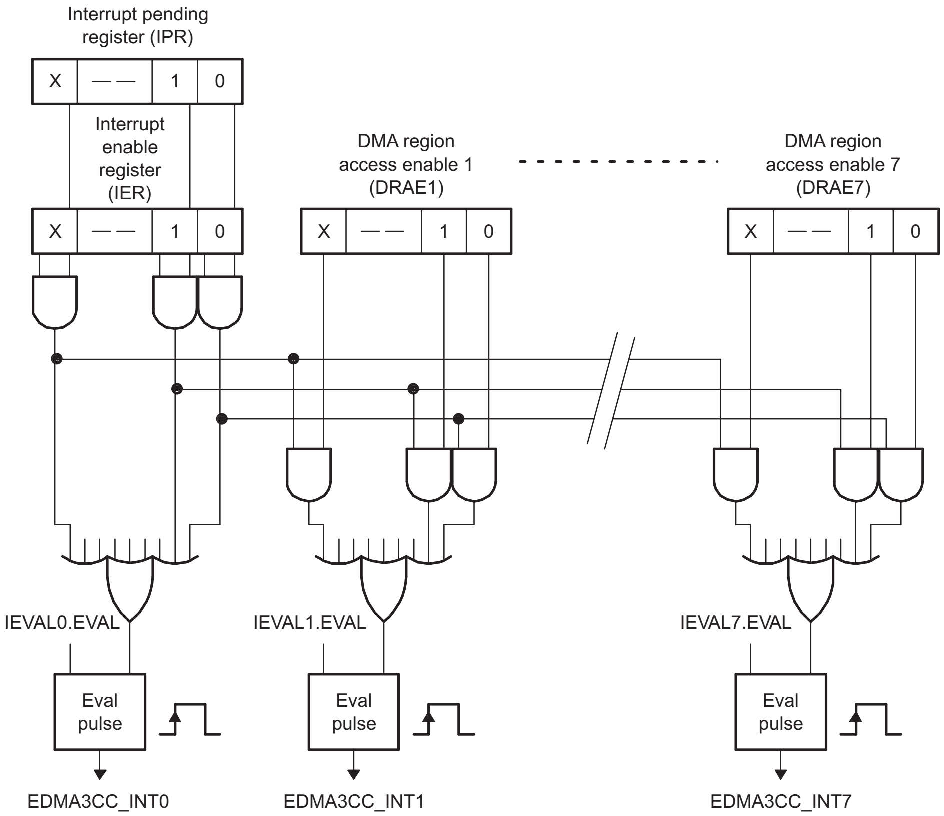
The EDMA3 channel controller has interrupt enable registers (IER/IERH) and each bit location in IER/IERH serves as a primary enable for the corresponding interrupt pending registers (IPR/IPRH).

All of the interrupt registers (IER, IESR, IECR, and IPR) are either manipulated from the global DMA channel region, or by the DMA channel shadow regions. The shadow regions provide a view to the same set of physical registers that are in the global region.

The EDMA3 channel controller has a hierarchical completion interrupt scheme that uses a single set of interrupt pending registers (IPR/IPRH) and single set of interrupt enable registers (IER/IERH). The programmable DMA region access enable registers (DRAE/DRAEH) provides a second level of interrupt masking. The global region interrupt output is gated based on the enable mask that is provided by IER/IERH. see Figure 10-16

The region interrupt outputs are gated by IER and the specific DRAE/DRAEH associated with the region. See Figure 10-16.

Figure 10-16. Interrupt Diagram



For the EDMA3CC to generate the transfer completion interrupts that are associated with each shadow region, the following conditions must be true:

- EDMA3CC_INT0: (IPR.E0 & IER.E0 & DRAE0.E0) | (IPR.E1 & IER.E1 & DRAE0.E1) | …|(IPRH.E63 & IERH.E63 & DRAHE0.E63)
- EDMA3CC_INT1: (IPR.E0 & IER.E0 & DRAE1.E0) | (IPR.E1 & IER.E1 & DRAE1.E1) | …| (IPRH.E63 & IERH.E63 & DRAHE1.E63)
- EDMA3CC_INT2 : (IPR.E0 & IER.E0 & DRAE2.E0) | (IPR.E1 & IER.E1 & DRAE2.E1) | …|(IPRH.E63 & IERH.E63 & DRAHE2.E63)....

- Up to EDMA3CC_INT7 : (IPR.E0 & IER.E0 & DRAE7.E0) | (IPR.E1 & IER.E1 & DRAE7.E1) | …|(IPRH.E63 & IERH.E63 & DRAEH7.E63)

NOTE: The DRAE/DRAEH for all regions are expected to be set up at system initialization and to remain static for an extended period of time. The interrupt enable registers should be used for dynamic enable/disable of individual interrupts.

Because there is no relation between the TCC value and the DMA/QDMA channel, it is possible, for example, for DMA channel 0 to have the OPT.TCC = 63 in its associated PaRAM set. This would mean that if a transfer completion interrupt is enabled (OPT.TCINTEN or OPT.ITCINTEN is set), then based on the TCC value, IPRH.E63 is set up on completion. For proper channel operations and interrupt generation using the shadow region map, you must program the DRAE/DRAEH that is associated with the shadow region to have read/write access to both bit 0 (corresponding to channel 0) and bit 63 (corresponding to IPRH bit that is set upon completion).

10.3.9.1.2 Clearing Transfer Completion Interrupts

Transfer completion interrupts that are latched to the interrupt pending registers (IPR/IPRH) are cleared by writing a 1 to the corresponding bit in the interrupt pending clear register (ICR/ICRH). For example, a write of 1 to ICR.E0 clears a pending interrupt in IPR.E0.

If an incoming transfer completion code (TCC) gets latched to a bit in IPR/IPRH, then additional bits that get set due to a subsequent transfer completion will not result in asserting the EDMA3CC completion interrupt. In order for the completion interrupt to be pulsed, the required transition is from a state where no enabled interrupts are set to a state where at least one enabled interrupt is set.

10.3.9.2 EDMA3 Interrupt Servicing

Upon completion of a transfer (early or normal completion), the EDMA3 channel controller sets the appropriate bit in the interrupt pending registers (IPR/IPRH), as the transfer completion codes specify. If the completion interrupts are appropriately enabled, then the CPU enters the interrupt service routine (ISR) when the completion interrupt is asserted.

After servicing the interrupt, the ISR should clear the corresponding bit in IPR/IPRH, thereby enabling recognition of future interrupts. The EDMA3CC will only assert additional completion interrupts when all IPR/IPRH bits clear.

When one interrupt is serviced many other transfer completions may result in additional bits being set in IPR/IPRH, thereby resulting in additional interrupts. Each of the bits in IPR/IPRH may need different types of service; therefore, the ISR may check all pending interrupts and continue until all of the posted interrupts are serviced appropriately.

Examples of pseudo code for a CPU interrupt service routine for an EDMA3CC completion interrupt are shown in Example 10-2 and Example 10-3.

The ISR routine in Example 10-2 is more exhaustive and incurs a higher latency.

Example 10-2. Interrupt Servicing

The pseudo code:

1. Reads the interrupt pending register (IPR/IPRH).
2. Performs the operations needed.
3. Writes to the interrupt pending clear register (ICR/ICRH) to clear the corresponding IPR/IPRH bits.
4. Reads IPR/IPRH again:
   a. If IPR/IPRH is not equal to 0, repeat from step 2 (implies occurrence of new event between step 2 to step 4).
   b. If IPR/IPRH is equal to 0, this should assure you that all of the enabled interrupts are inactive.

Example 10-2. Interrupt Servicing (continued)

NOTE: An event may occur during step 4 while the IPR/IPRH bits are read as 0 and the application is still in the interrupt service routine. If this happens, a new interrupt is recorded in the device interrupt controller and a new interrupt generates as soon as the application exits in the interrupt service routine.

Example 10-3 is less rigorous, with less burden on the software in polling for set interrupt bits, but can occasionally cause a race condition as mentioned above.

Example 10-3. Interrupt Servicing

If you want to leave any enabled and pending (possibly lower priority) interrupts; you must force the interrupt logic to reassert the interrupt pulse by setting the EVAL bit in the interrupt evaluation register (IEVAL).

The pseudo code is as follows:

1. Enters ISR.
2. Reads IPR/IPRH.
3. For the condition that is set in IPR/IPRH that you want to service, do the following:
   a. Service interrupt as the application requires.
   b. Clear the bit for serviced conditions (others may still be set, and other transfers may have resulted in returning the TCC to EDMA3CC after step 2).
4. Reads IPR/IPRH prior to exiting the ISR:
   a. If IPR/IPRH is equal to 0, then exit the ISR.
   b. If IPR/IPRH is not equal to 0, then set IEVAL so that upon exit of ISR, a new interrupt triggers if any enabled interrupts are still pending.

10.3.9.3 Interrupt Evaluation Operations

The EDMA3CC has interrupt evaluate registers (IEVAL) that exist in the global region and in each shadow region. The registers in the shadow region are the only registers in the DMA channel shadow region memory map that are not affected by the settings for the DMA region access enable registers (DRAE/DRAEH). Writing a 1 to the EVAL bit in the registers that are associated with a particular shadow region results in pulsing the associated region interrupt (global or shadow), if any enabled interrupt (via IER/IERH) is still pending (IPR/IPRH). This register assures that the CPU does not miss the interrupts (or the EDMA3 master associated with the shadow region) if the software architecture chooses not to use all interrupts. See Example 10-3 for the use of IEVAL in the EDMA3 interrupt service routine (ISR).

Similarly, an error evaluation register (EEVAL) exists in the global region. Writing a 1 to the EVAL bit in EEVAL causes the pulsing of the error interrupt if any pending errors are in EMR/EMRH, QEMR, or CCERR. The EVAL bit must be written with 1 to clear interrupts to the INTC, even when all error interrupt registers are cleared. See Section 10.3.9.4, *Error Interrupts*, for additional information regarding error interrupts.

NOTE: While using IEVAL for shadow region completion interrupts, you should make sure that the IEVAL operated upon is from that particular shadow region memory map.

10.3.9.4 Error Interrupts

The EDMA3CC error registers provide the capability to differentiate error conditions (event missed, threshold exceed, etc.). Additionally, setting the error bits in these registers results in asserting the EDMA3CC error interrupt. If the EDMA3CC error interrupt is enabled in the device interrupt controllers, then it allows the CPUs to handle the error conditions.

The EDMA3CC has a single error interrupt (EDMA3CC_ERRINT) that is asserted for all EDMA3CC error conditions. There are four conditions that cause the error interrupt to pulse:

- DMA missed events: for all 64 DMA channels. DMA missed events are latched in the event missed registers (EMR/EMRH).
- QDMA missed events: for all 8 QDMA channels. QDMA missed events are latched in the QDMA event missed register (QEMR).
- Threshold exceed: for all event queues. These are latched in EDMA3CC error register (CCERR).
- TCC error: for outstanding transfer requests that are expected to return completion code (TCCHEN or TCINTEN bit in OPT is set to 1) exceeding the maximum limit of 63. This is also latched in the EDMA3CC error register (CCERR).

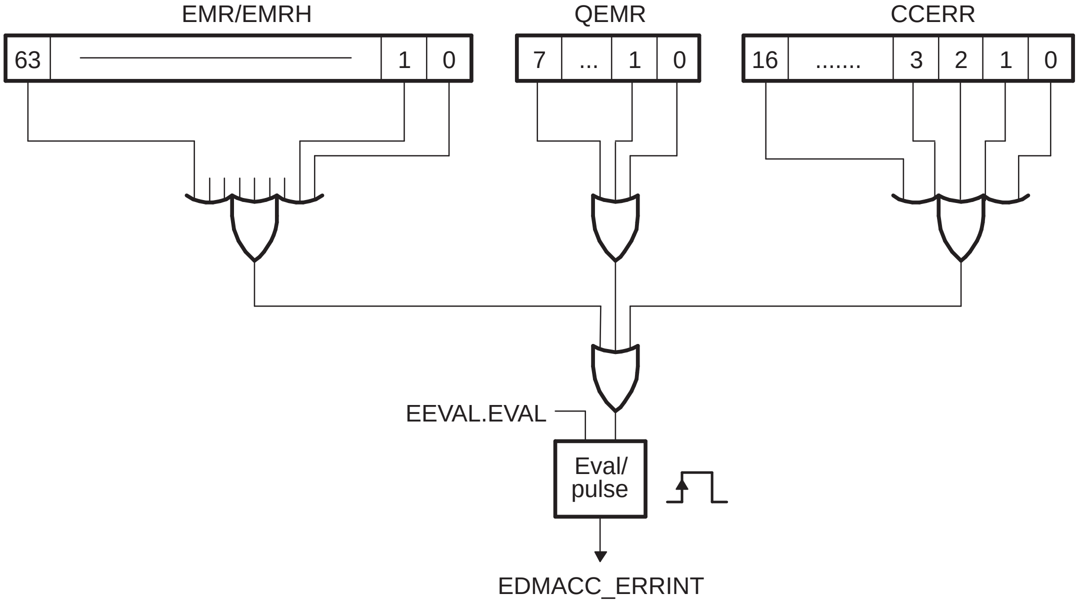
Figure 10-17 illustrates the EDMA3CC error interrupt generation operation.

If any of the bits are set in the error registers due to any error condition, the EDMA3CC_ERRINT is always asserted, as there are no enables for masking these error events. Similar to transfer completion interrupts (EDMA3CC_INT), the error interrupt also only pulses when the error interrupt condition transitions from no errors being set to at least one error being set. If additional error events are latched prior to the original error bits clearing, the EDMA3CC does not generate additional interrupt pulses.

To reduce the burden on the software, there is an error evaluate register (EEVAL) that allows re-evaluation of pending set error events/bits, similar to the interrupt evaluate register (IEVAL). You can use this so that the CPU does not miss any error events. You must write a 1 to the EEVAL.EVAL bit to clear interrupts to the INTC after all error registers have been cleared.

NOTE: It is good practice to enable the error interrupt in the device interrupt controller and to associate an interrupt service routine with it to address the various error conditions appropriately. Doing so puts less burden on the software (polling for error status); additionally, it provides a good debug mechanism for unexpected error conditions.

Figure 10-17. Error Interrupt Operation



10.3.10 Memory Protection

The EDMA3 channel controller supports two kinds of memory protection: active and proxy.

10.3.10.1 Active Memory Protection

Active memory protection is a feature that allows or prevents read and write accesses (by any EDMA3 programmer) to the EDMA3CC registers (based on permission characteristics that you program). Active memory protection is achieved by a set of memory protection permissions attribute (MPPA) registers.

The EDMA3CC register map is divided into three categories:

- a global region.
- a global channel region.
- eight shadow regions.

Each shadow region consists of the respective shadow region registers and the associated PaRAM. For more detailed information regarding the contents of a shadow region, refer to section Table 10-11.

Each of the eight shadow regions has an associated MPPA register (MPPA*n*) that defines the specific requestors and types of requests that are allowed to the regions resources.

The global channel region is also protected with a memory-mapped register (MPPAG). The MPPAG applies to the global region and to the global channel region, except the other MPPA registers themselves. For more detailed information on the list of the registers in each region, refer to the register memory-map in Table 10-18.

The MPPA*n* have a certain set of access rules. For more information, see the bit field descriptions of MPPA*n*.

Table 10-17 shows the accesses that are allowed or not allowed to the MPPAG and MPPA*n*. The active memory protection uses the PRIV and PRIVID attributes of the EDMA programmer. The PRIV is the privilege level (i.e., user vs. supervisor). The PRIVID refers to a privilege ID with a number that is associated with an EDMA3 programmer. See the device-specific data manual for the PRIVIDs that are associated with potential EDMA3 programmers.

Table 10-17. Allowed Accesses

Access	Supervisor	User
Read	Yes	Yes
Write	Yes	No

Table 10-18 describes the MPPA register mapping for the shadow regions (which includes shadow region registers and PaRAM addresses).

The region-based MPPA registers are used to protect accesses to the DMA shadow regions and the associated region PaRAM. Because there are eight regions, there are eight MPPA region registers (MPPA[0-7]).

Table 10-18. MPPA Registers to Region Assignment

Register	Registers Protect	Address Range	PaRAM Protect[1]	Address Range
MPPAG	Global Range	0000h-1FFCh	N/A	N/A
MPPA0	DMA Shadow 0	2000h-21FCh	1st octant	4000h-47FCh
MPPA1	DMA Shadow 1	2200h-23FCh	2nd octant	4800h-4FFCh
MPPA2	DMA Shadow 2	2400h-25FCh	3rd octant	5000h-57FCh
MPPA3	DMA Shadow 3	2600h-27FCh	4th octant	5800h-5FFCh
MPPA4	DMA Shadow 4	2800h-29FCh	5th octant	6000h-67FCh
MPPA5	DMA Shadow 5	2A00h-2BFCh	6th octant	6800h-6FFCh
MPPA6	DMA Shadow 6	2C00h-2DFCh	7th octant	7000h-77FCh
MPPA7	DMA Shadow 7	2E00h-2FFCh	8th octant	7800h-7FFCh

[1] The PARAM region is divided into 8 regions referred to as an octant.

Example Access denied.

Write access to shadow region 7's event enable set register (EESR):

1. The original value of the event enable register (EER) at address offset 0x1020 is 0x0.
2. The MPPA[7] is set to prevent user level accesses (UW = 0, UR = 0), but it allows supervisor level accesses (SW = 1, SR = 1) with a privilege ID of 0. (AID0 = 1).
3. An EDMA3 programmer with a privilege ID of 0 attempts to perform a user-level write of a value of 0xFF00FF00 to shadow region 7's event enable set register (EESR) at address offset 0x2E30. Note that the EER is a read-only register and the only way that you can write to it is by writing to the EESR. Also remember that there is only one physical register for EER, EESR, etc. and that the shadow regions only provide to the same physical set.
4. Since the MPPA[7] has UW = 0, though the privilege ID of the write access is set to 0, the access is not allowed and the EER is not written to.

Table 10-19. Example Access Denied

Register	Value	Description
EER (offset 0x1020)	0x0000 0000	Value in EER to begin with.
EESR (offset 0x2E30)	0xFF00 FF00 ↓	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA3 programmer with a privilege level of User and Privilege ID of 0.
MPPA[7] (offset 0x082C)	0x0000 04B0	Memory Protection Filter AID0 = 1, UW = 0, UR = 0, SW = 1, SR = 1.
	X	Access Denied
EER (offset 0x1020)	0x0000 0000	Final value of EER

Example Access Allowed

Write access to shadow region 7's event enable set register (EESR):

1. The original value of the event enable register (EER) at address offset 0x1020 is 0x0.
2. The MPPA[7] is set to allow user-level accesses (UW = 1, UR = 1) and supervisor-level accesses (SW = 1, SR = 1) with a privilege ID of 0. (AID0 = 1).
3. An EDMA3 programmer with a privilege ID of 0, attempts to perform a user-level write of a value of 0xABCD0123 to shadow region 7's event enable set register (EESR) at address offset 0x2E30. Note that the EER is a read-only register and the only way that you can write to it is by writing to the EESR. Also remember that there is only one physical register for EER, EESR, etc. and that the shadow regions only provide to the same physical set.
4. Since the MPPA[7] has UW = 1 and AID0 = 1, the user-level write access is allowed.
5. Remember that accesses to shadow region registers are masked by their respective DRAE register. In this example, the DRAE[7] is set of 0x9FF00FC2.
6. The value finally written to EER is 0x8BC00102.

Table 10-20. Example Access Allowed

Register	Value	Description
EER (offset 0x1020)	0x0000 0000	Value in EER to begin with.
EESR (offset 0x2E30)	0xFF00 FF00	Value attempted to be written to shadow region 7's EESR. This is done by an EDMA3 programmer with a privilege level of User and Privilege ID of 0.
MPPA[7] (offset 0x082C)	0x0000 04B3	Memory Protection Filter AID = 1, UW = 1, UR = 1, SW = 1, SR = 1.
	√ ↓	Access allowed.
DRAE[7] (offset 0x0378)	0x9FF0 0FC2 ↓	DMA Region Access Enable Filter
EESR (offset 0x2E30)	0x8BC0 0102 ↓	Value written to shadow region 7's EESR. This is done by an EDMA3 programmer with a privilege level of User and a Privilege ID of 0.
EER (offset 0x1020)	↓ 0xBC0 0102	Final value of EER.

10.3.10.2 Proxy Memory Protection

Proxy memory protection allows an EDMA3 transfer programmed by a given EDMA3 programmer to have its permissions travel with the transfer through the EDMA3TC. The permissions travel along with the read transactions to the source and the write transactions to the destination endpoints. The PRIV bit and PRIVID bit in the channel options parameter (OPT) is set with the EDMA3 programmer's PRIV value and PRIVID values, respectively, when any part of the PaRAM set is written.

The PRIV is the privilege level (i.e., user vs. supervisor). The PRIVID refers to a privilege ID with a number that is associated with an EDMA3 programmer.

See the data manual for the PRIVIDs that are associated with potential EDMA3 programmers.

These options are part of the TR that are submitted to the transfer controller. The transfer controller uses the above values on their respective read and write command bus so that the target endpoints can perform memory protection checks based on these values.

Consider a parameter set that is programmed by a CPU in user privilege level for a simple transfer with the source buffer on an L2 page and the destination buffer on an L1D page. The PRIV is 0 for user-level and the CPU has a PRIVID of 0.

The PaRAM set is shown in Figure 10-18.

Figure 10-18. PaRAM Set Content for Proxy Memory Protection Example

(a) EDMA3 Parameters

Parameter Contents		Parameter	
0010 0007h		Channel Options Parameter (OPT)	
009F 0000h		Channel Source Address (SRC)	
0001h	0004h	Count for 2nd Dimension (BCNT)	Count for 1st Dimension (ACNT)
00F0 7800h		Channel Destination Address (DST)	
0001h	0001h	Destination BCNT Index (DSTBIDX)	Source BCNT Index (SRCBIDX)
0000h	FFFFh	BCNT Reload (BCNTRLD)	Link Address (LINK)
0001h	1000h	Destination CCNT Index (DSTCIDX)	Source CCNT Index (SRCCIDX)
0000h	0001h	Reserved	Count for 3rd Dimension (CCNT)

Figure 10-19. Channel Options Parameter (OPT) Example

(b) Channel Options Parameter (OPT) Content

31	30	29 28	27 24	23	22	21	20	19 18	17 16
0	0	00	0000	0	0	0	1	00	00
PRIV	Rsvd	Rsvd	PRIVID	ITCCHEN	TCCHEN	ITCINTEN	TCINTEN	Reserved	TCC

15 12	11	10 8	7 4	3	2	1	0
0000	0	000	0000	0	1	1	1
TCC	TCCMOD	FWID	Reserved	STATIC	SYNCDIM	DAM	SAM

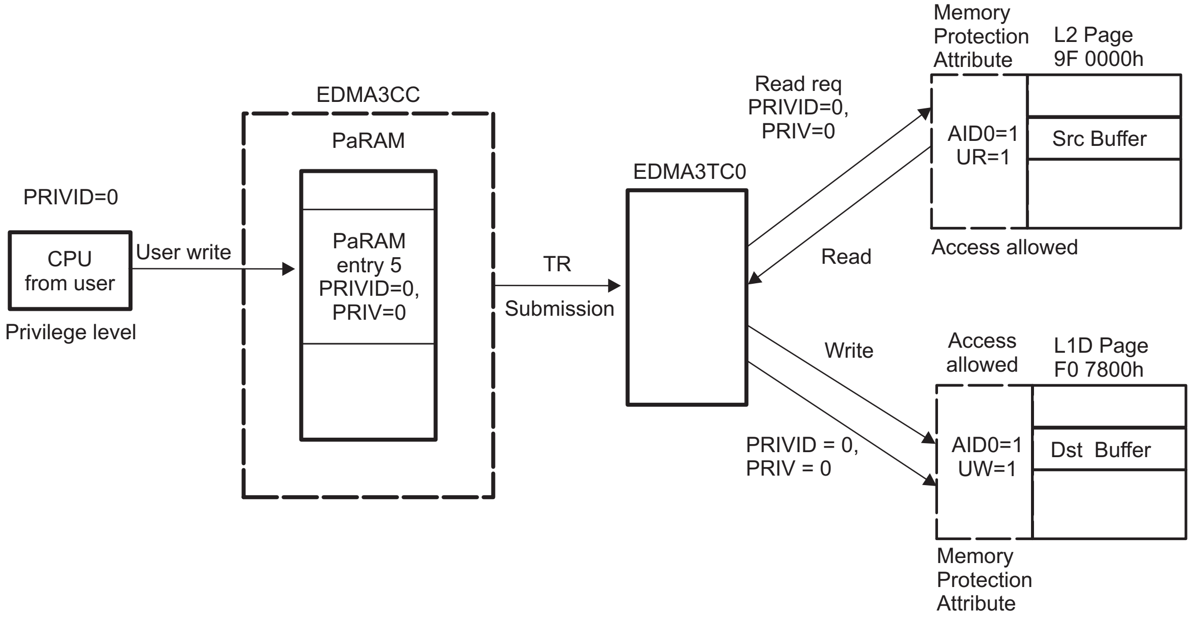
The PRIV and PRIVID information travels along with the read and write requests that are issued to the source and destination memories.

For example, if the access attributes that are associated with the L2 page with the source buffer only allow supervisor read, write accesses (SR,SW), the user-level read request above is refused. Similarly, if the access attributes that are associated with the L1D page with the destination buffer only allow supervisor read and write accesses (SR, SW), the user-level write request above is refused. For the transfer to succeed, the source and destination pages should have user-read and user-write permissions, respectively, along with allowing accesses from a PRIVID 0.

Because the programmer's privilege level and privilege identification travel with the read and write requests, EDMA3 acts as a proxy.

Figure 10-20 illustrates the propagation of PRIV and PRIVID at the boundaries of all the interacting entities (CPU, EDMA3CC, EDMA3TC, and slave memories).

Figure 10-20. Proxy Memory Protection Example



10.3.11 Event Queues

Event queues are a part of the EDMA3 channel controller. Event queues form the interface between the event detection logic in the EDMA3CC and the transfer request (TR) submission logic of the EDMA3CC. Each queue is 16 entries deep; thus, each event queue can queue a maximum of 16 events. If there are more than 16 events, then the events that cannot find a place in the event queue remain set in the associated event register and the CPU does not stall.

There are four event queues for the device: Queue0, Queue1, Queue2, and Queue3. Events in Queue0 result in submission of its associated transfer requests (TRs) to TC0. Similarly, transfer requests that are associated with events in Queue3 are submitted to TC3.

An event that wins prioritization against other DMA and/or QDMA pending events is placed at the tail of the appropriate event queue. Each event queue is serviced in FIFO order. Once the event reaches the head of its queue and the corresponding transfer controller is ready to receive another TR, the event is de-queued and the PaRAM set corresponding to the de-queued event is processed and submitted as a transfer request packet (TRP) to the associated EDMA3 transfer controller.

Queue0 has highest priority and Queue3 has the lowest priority, if Queue0 and Queue1 both have at least one event entry and if both TC0 and TC1 can accept transfer requests, then the event in Queue0 is de-queued first and its associated PaRAM set is processed and submitted as a transfer request (TR) to TC0.

See Section 10.3.11.4 for system-level performance considerations. All of the event entries in all of the event queues are software readable (not writeable) by accessing the event entry registers (Q0E0, Q0E1,…Q1E15, and so on). Each event entry register characterizes the queued event in terms of the type of event (manual, event, chained or auto-triggered) and the event number. For more information, see the bit fields in the queue event entry (QxEy) registers.

10.3.11.1 DMA/QDMA Channel to Event Queue Mapping

Each of the 64 DMA channels and eight QDMA channels are programmed independently to map to a specific queue, using the DMA queue number register (DMAQNUM) and the QDMA queue number register (QDMANUM). The mapping of DMA/QDMA channels is critical to achieving the desired performance level for the EDMA and most importantly, in meeting real-time deadlines. See Section 10.3.11.4.

NOTE: If an event is ready to be queued and both the event queue and the EDMA3 transfer controller that is associated to the event queue are empty, then the event bypasses the event queue, and moves the PaRAM processing logic, and eventually to the transfer request submission logic for submission to the EDMA3TC. In this case, the event is not logged in the event queue status registers.

10.3.11.2 Queue RAM Debug Visibility

There are four event queues and each queue has 16 entries. These 16 entries are managed in a circular FIFO manner. There is a queue status register (QSTAT) associated with each queue. These along with all of the 16 entries per queue can be read via registers QSTAT*n* and QxEy, respectively.

These registers provide user visibility and may be helpful while debugging real-time issues (typically post-mortem), involving multiple events and event sources. The event queue entry register (Q*x*E*y*) uniquely identifies the specific event type (event-triggered, manually-triggered, chain-triggered, and QDMA events) along with the event number (for all DMA/QDMA event channels) that are in the queue or have been de-queued (passed through the queue).

Each of the 16 entries in the event queue are read using the EDMA3CC memory-mapped register. By reading the event queue, you see the history of the last 16 TRs that have been processed by the EDMA3 on a given queue. This provides user/software visibility and is helpful for debugging real-time issues (typically post-mortem), involving multiple events and event sources.

The queue status register (QSTAT*n*) includes fields for the start pointer (STRTPTR) which provides the offset to the head entry of an event. It also includes a field called NUMVAL that provides the total number of valid entries residing in the event queue at a given instance of time. The STRTPTR may be used to index appropriately into the 16 event entries. NUMVAL number of entries starting from STRTPTR are indicative of events still queued in the respective queue. The remaining entry may be read to determine what's already de-queued and submitted to the associated transfer controller.

10.3.11.3 Queue Resource Tracking

The EDMA3CC event queue includes watermarking/threshold logic that allows you to keep track of maximum usage of all event queues. This is useful for debugging real-time deadline violations that may result from head-of-line blocking on a given EDMA3 event queue.

You can program the maximum number of events that can queue up in an event queue by programming the threshold value (between 0 to 15) in the queue watermark threshold A register (QWMTHRA). The maximum queue usage is recorded actively in the watermark (WM) field of the queue status register (QSTAT*n*) that keeps getting updated based on a comparison of number of valid entries, which is also visible in the NUMVAL bit in QSTAT*n* and the maximum number of entries (WM bit in QSTAT*n*).

If the queue usage is exceeded, this status is visible in the EDMA3CC registers: the QTHRXCD*n* bit in the channel controller error register (CCERR) and the THRXCD bit in QSTAT*n*, where *n* stands for the event queue number. Any bits that are set in CCERR also generate an EDMA3CC error interrupt.

10.3.11.4 Performance Considerations

The main system bus infrastructure (L3) arbitrates bus requests from all of the masters (TCs, CPU(S), and other bus masters) to the shared slave resources (peripherals and memories).

The priorities of transfer requests (read and write commands) from the EDMA3 transfer controllers with respect to other masters within the system crossbar are programmed using the queue priority register (QUEPRI). QUEPRI programs the priority of the event queues (or indirectly, TC0-TC3, because Queue*N* transfer requests are submitted to TC*N*).

Therefore, the priority of unloading queues has a secondary affect compared to the priority of the transfers as they are executed by the EDMA3TC (dictated by the priority set using QUEPRI).

10.3.12 EDMA3 Transfer Controller (EDMA3TC)

The EDMA3 channel controller is the user-interface of the EDMA3 and the EDMA3 transfer controller (EDMA3TC) is the data movement engine of the EDMA3. The EDMA3CC submits transfer requests (TR) to the EDMA3TC and the EDMA3TC performs the data transfers dictated by the TR; thus, the EDMA3TC is a slave to the EDMA3CC.

10.3.12.1 Architecture Details

10.3.12.1.1 Command Fragmentation

The TC read and write controllers in conjunction with the source and destination register sets are responsible for issuing optimally-sized reads and writes to the slave endpoints. An optimally-sized command is defined by the transfer controller default burst size (DBS), which is defined in Section 10.3.12.5.

The EDMA3TC attempts to issue the largest possible command size as limited by the DBS value or the ACNT/BCNT value of the TR. EDMA3TC obeys the following rules:

- The read/write controllers always issue commands less than or equal to the DBS value.
- The first command of a 1D transfer command always aligns the address of subsequent commands to the DBS value.

Table 10-21 lists the TR segmentation rules that are followed by the EDMA3TC. In summary, if the ACNT value is larger than the DBS value, then the EDMA3TC breaks the ACNT array into DBS-sized commands to the source/destination addresses. Each BCNT number of arrays are then serviced in succession.

For BCNT arrays of ACNT bytes (that is, a 2D transfer), if the ACNT value is less than or equal to the DBS value, then the TR may be optimized into a 1D-transfer in order to maximize efficiency. The optimization takes place if the EDMA3TC recognizes that the 2D-transfer is organized as a single dimension (ACNT == BIDX) and the ACNT value is a power of 2.

Table 10-21 lists conditions in which the optimizations are performed.

Table 10-21. Read/Write Command Optimization Rules

ACNT ≤ DBS	ACNT is power of 2	BIDX = ACNT	BCNT ≤ 1023	SAM/DAM = Increment	Description
Yes	Yes	Yes	Yes	Yes	Optimized
No	x	x	x	x	Not Optimized
x	No	x	x	x	Not Optimized
x	x	No	x	x	Not Optimized
x	x	x	No	x	Not Optimized
x	x	x	x	No	Not Optimized

10.3.12.1.2 TR Pipelining

TR pipelining refers to the ability of the source active set to proceed ahead of the destination active set. Essentially, the reads for a given TR may already be in progress while the writes of a previous TR may not have completed.

The number of outstanding TRs is limited by the number of destination FIFO register entries.

TR pipelining is useful for maintaining throughput on back-to-back small TRs. It minimizes the startup overhead because reads start in the background of a previous TR writes.

Example 10-4. Command Fragmentation (DBS = 64)

The pseudo code:

1. ACNT = 8, BCNT = 8, SRCBIDX = 8, DSTBIDX = 10, SRCADDR = 64, DSTADDR = 191

   Read Controller: This is optimized from a 2D-transfer to a 1D-transfer such that the read side is equivalent to ACNT = 64, BCNT = 1.

   Cmd0 = 64 byte

   Write Controller: Because DSTBIDX != ACNT, it is not optimized.

   Cmd0 = 8 byte, Cmd1 = 8 byte, Cmd2 = 8 byte, Cmd3 = 8 byte, Cmd4 = 8 byte, Cmd5 = 8 byte, Cmd6 = 8 byte, Cmd7 = 8 byte.
2. ACNT=128, BCNT = 1,SRCADDR = 63, DSTADDR = 513

   Read Controller: Read address is not aligned.

   Cmd0 = 1 byte, (now the SRCADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 63 bytes

   Write Controller: The write address is also not aligned.

   Cmd0 = 63 bytes, (now the DSTADDR is aligned to 64 for the next command)

   Cmd1 = 64 bytes

   Cmd2 = 1 byte

10.3.12.1.3 Performance Tuning

By default, reads are as issued as fast as possible. In some cases, the reads issued by the EDMA3TC could fill the available command buffering for a slave, delaying other (potentially higher priority) masters from successfully submitting commands to that slave. The rate at which read commands are issued by the EDMA3TC is controlled by the RDRATE register. The RDRATE register defines the number of cycles that the EDMA3TC read controller waits before issuing subsequent commands for a given TR, thus minimizing the chance of the EDMA3TC consuming all available slave resources. The RDRATE value should be set to a relatively small value if the transfer controller is targeted for high priority transfers and to a higher value if the transfer controller is targeted for low priority transfers.

In contrast, the Write Interface does not have any performance turning knobs because writes always have an interval between commands as write commands are submitted along with the associated write data.

10.3.12.2 Memory Protection

The transfer controller plays an important role in handling proxy memory protection. There are two access properties associated with a transfer: for instance, the privilege id (system-wide identification assigned to a master) of the master initiating the transfer, and the privilege level (user versus supervisor) used to program the transfer. This information is maintained in the PaRAM set when it is programmed in the channel controller. When a TR is submitted to the transfer controller, this information is made available to the EDMA3TC and used by the EDMA3TC while issuing read and write commands. The read or write commands have the same privilege identification, and privilege level as that programmed in the EDMA3 transfer in the channel controller.

10.3.12.3 Error Generation

Errors are generated if enabled under three conditions:

- EDMA3TC detection of an error signaled by the source or destination address.
- Attempt to read or write to an invalid address in the configuration memory map.
- Detection of a constant addressing mode TR violating the constant addressing mode transfer rules (the source/destination addresses and source/destination indexes must be aligned to 32 bytes).

Either or all error types may be disabled. If an error bit is set and enabled, the error interrupt for the concerned transfer controller is pulsed.

10.3.12.4 Debug Features

The DMA program register set, DMA source active register set, and the destination FIFO register set are used to derive a brief history of TRs serviced through the transfer controller.

Additionally, the EDMA3TC status register (TCSTAT) has dedicated bit fields to indicate the ongoing activity within different parts of the transfer controller:

- The SRCACTV bit indicates whether the source active set is active.
- The DSTACTV bit indicates the number of TRs resident in the destination register active set at a given instance.
- The PROGBUSY bit indicates whether a valid TR is present in the DMA program set.

If the TRs are in progression, caution must be used and you must realize that there is a chance that the values read from the EDMA3TC status registers will be inconsistent since the EDMA3TC may change the values of these registers due to ongoing activities.

It is recommended that you ensure no additional submission of TRs to the EDMA3TC in order to facilitate ease of debug.

10.3.12.4.1 Destination FIFO Register Pointer

The destination FIFO register pointer is implemented as a circular buffer with the start pointer being DFSTRTPTR and a buffer depth of usually 2 or 4. The EDMA3TC maintains two important status details in TCSTAT that may be used during advanced debugging, if necessary. The DFSTRTPTR is a start pointer, that is, the index to the head of the destination FIFO register. The DSTACTV is a counter for the number of valid (occupied) entries. These registers may be used to get a brief history of transfers.

Examples of some register field values and their interpretation:

- DFSTRTPTR = 0 and DSTACTV = 0 implies that no TRs are stored in the destination FIFO register.
- DFSTRTPTR = 1 and DSTACTV = 2h implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 1 and the second pending TR is read from the destination FIFO register entry 2.
- DFSTRTPTR = 3h and DSTACTV = 2h implies that two TRs are present. The first pending TR is read from the destination FIFO register entry 3 and the second pending TR is read from the destination FIFO register entry 0.

10.3.12.5 EDMA3TC Configuration

Table 10-22 provides the configuration of the individual EDMA3 transfer controllers present on the device. The default burst size (DBS) for each transfer controller is configurable using the TPTC_CFG register in the control module.

Table 10-22. EDMA3 Transfer Controller Configurations

Name	TC0	TC1	TC2	TC3
FIFOSIZE	512 bytes	512 bytes	512 bytes	512 bytes
BUSWIDTH	16 bytes	16 bytes	16 bytes	16 bytes
DSTREGDEPTH	4 entries	4 entries	4 entries	4 entries
DBS	Configurable	Configurable	Configurable	Configurable

10.3.13 Event Dataflow

This section summarizes the data flow of a single event, from the time the event is latched to the channel controller to the time the transfer completion code is returned. The following steps list the sequence of EDMA3CC activity:

1. Event is asserted from an external source (peripheral or external interrupt). This also is similar for a manually-triggered, chained-triggered, or QDMA-triggered event. The event is latched into the ER.E*n*/ERH.E*n* (or CER.E*n*/CERH.E*n*, ESR.E*n* /ESRH.E*n*, QER.E*n*) bit.
2. Once an event is prioritized and queued into the appropriate event queue, the SER.E*n*\SERH.E*n* (or QSER.E*n*) bit is set to inform the event prioritization/processing logic to disregard this event since it is already in the queue. Alternatively, if the transfer controller and the event queue are empty, then the event bypasses the queue.
3. The EDMA3CC processing and the submission logic evaluates the appropriate PaRAM set and determines whether it is a non-null and non-dummy transfer request (TR).
4. The EDMA3CC clears the ER.E*n*/ERH.E*n* (or CER.E*n*/CERH.E*n*, ESR.E*n*/ESRH.E*n*, QER.E*n*) bit and the SER.E*n*/SERH.E*n* bit as soon as it determines the TR is non-null. In the case of a null set, the SER.E*n*/SERH.E*n* bit remains set. It submits the non-null/non-dummy TR to the associated transfer controller. If the TR was programmed for early completion, the EDMA3CC immediately sets the interrupt pending register (IPR.I[TCC]/IPRH.I[TCC]-32).
5. If the TR was programmed for normal completion, the EDMA3CC sets the interrupt pending register (IPR.I[TCC]/IPRH.I[TCC]) when the EDMA3TC informs the EDMA3CC about completion of the transfer (returns transfer completion codes).
6. The EDMA3CC programs the associated EDMA3TC*n*'s Program Register Set with the TR.
7. The TR is then passed to the Source Active set and the DST FIFO Register Set, if both the register sets are available.
8. The Read Controller processes the TR by issuing read commands to the source slave endpoint. The Read Data lands in the Data FIFO of the EDMA3TC*n*.
9. As soon as sufficient data is available, the Write Controller begins processing the TR by issuing write commands to the destination slave endpoint.
10. This continues until the TR completes and the EDMA3TC*n* then signals completion status to the EDMA3CC.

10.3.14 EDMA3 Prioritization

The EDMA3 controller has many implementation rules to deal with concurrent events/channels, transfers, etc. The following subsections detail various arbitration details whenever there might be occurrence of concurrent activity. Figure 10-21 shows the different places EDMA3 priorities come into play.

10.3.14.1 Channel Priority

The DMA event registers (ER and ERH) capture up to 64 events; likewise, the QDMA event register (QER) captures QDMA events for all QDMA channels; therefore, it is possible for events to occur simultaneously on the DMA/QDMA event inputs. For events arriving simultaneously, the event associated with the lowest channel number is prioritized for submission to the event queues (for DMA events, channel 0 has the highest priority and channel 63 has the lowest priority; similarly, for QDMA events, channel 0 has the highest priority and channel 7 has the lowest priority). This mechanism only sorts simultaneous events for submission to the event queues.

If a DMA and QDMA event occurs simultaneously, the DMA event always has prioritization against the QDMA event for submission to the event queues.

10.3.14.2 Trigger Source Priority

If a DMA channel is associated with more than one trigger source (event trigger, manual trigger, and chain trigger), and if multiple events are set simultaneously for the same channel (ER.E*n* = 1, ESR.E*n* = 1 , CER.E*n* = 1) , then the EDMA3CC always services these events in the following priority order: event trigger (via ER) is higher priority than chain trigger (via CER) and chain trigger is higher priority than manual trigger (via ESR).

This implies that if for channel 0, both ER.E0 = 1 and CER.E0 = 1 at the same time, then the ER.E0 event is always queued before the CER.E0 event.

10.3.14.3 Dequeue Priority

The priority of the associated transfer request (TR) is further mitigated by which event queue is being used for event submission (dictated by DMAQNUM and QDMAQNUM). For submission of a TR to the transfer request, events need to be de-queued from the event queues. Queue 0 has the highest dequeue priority and queue 3 the lowest.

10.3.14.4 System (Transfer Controller) Priority

INIT_PRIORITY_0 and INIT_PRIORITY_1 registers in the chip configuration module are used to configure the EDMA TC's priority through the system bus infrastructure. Additionally, the priority settings for DDR memory accesses are defined in the dynamic memory manager (DMM).

NOTE: The default priority for all TCs is the same, 0 or highest priority relative to other masters. It is recommended that this priority be changed based on system level considerations, such as real-time deadlines for all masters including the priority of the transfer controllers with respect to each other.

10.3.15 EDMA3 Operating Frequency (Clock Control)

The EDMA3 channel controller and transfer controller are clocked from PLL_L3 SYSCLK4. The EDMA3 system runs at the L3 clock frequency.

10.3.16 Reset Considerations

A hardware reset resets the EDMA3 (EDMA3CC and EDMA3TC) and the EDMA3 configuration registers. The PaRAM memory contents are undefined after device reset and you should not rely on parameters to be reset to a known state. The PaRAM entry must be initialized to a desired value before it is used.

10.3.17 Power Management

The EDMA3 (EDMA3CC and EDMA3TC) can be placed in reduced-power modes to conserve power during periods of low activity. The power management of the peripheral is controlled by the power reset clock management (PRCM). The PRCM acts as a master controller for power management for all peripherals on the device.

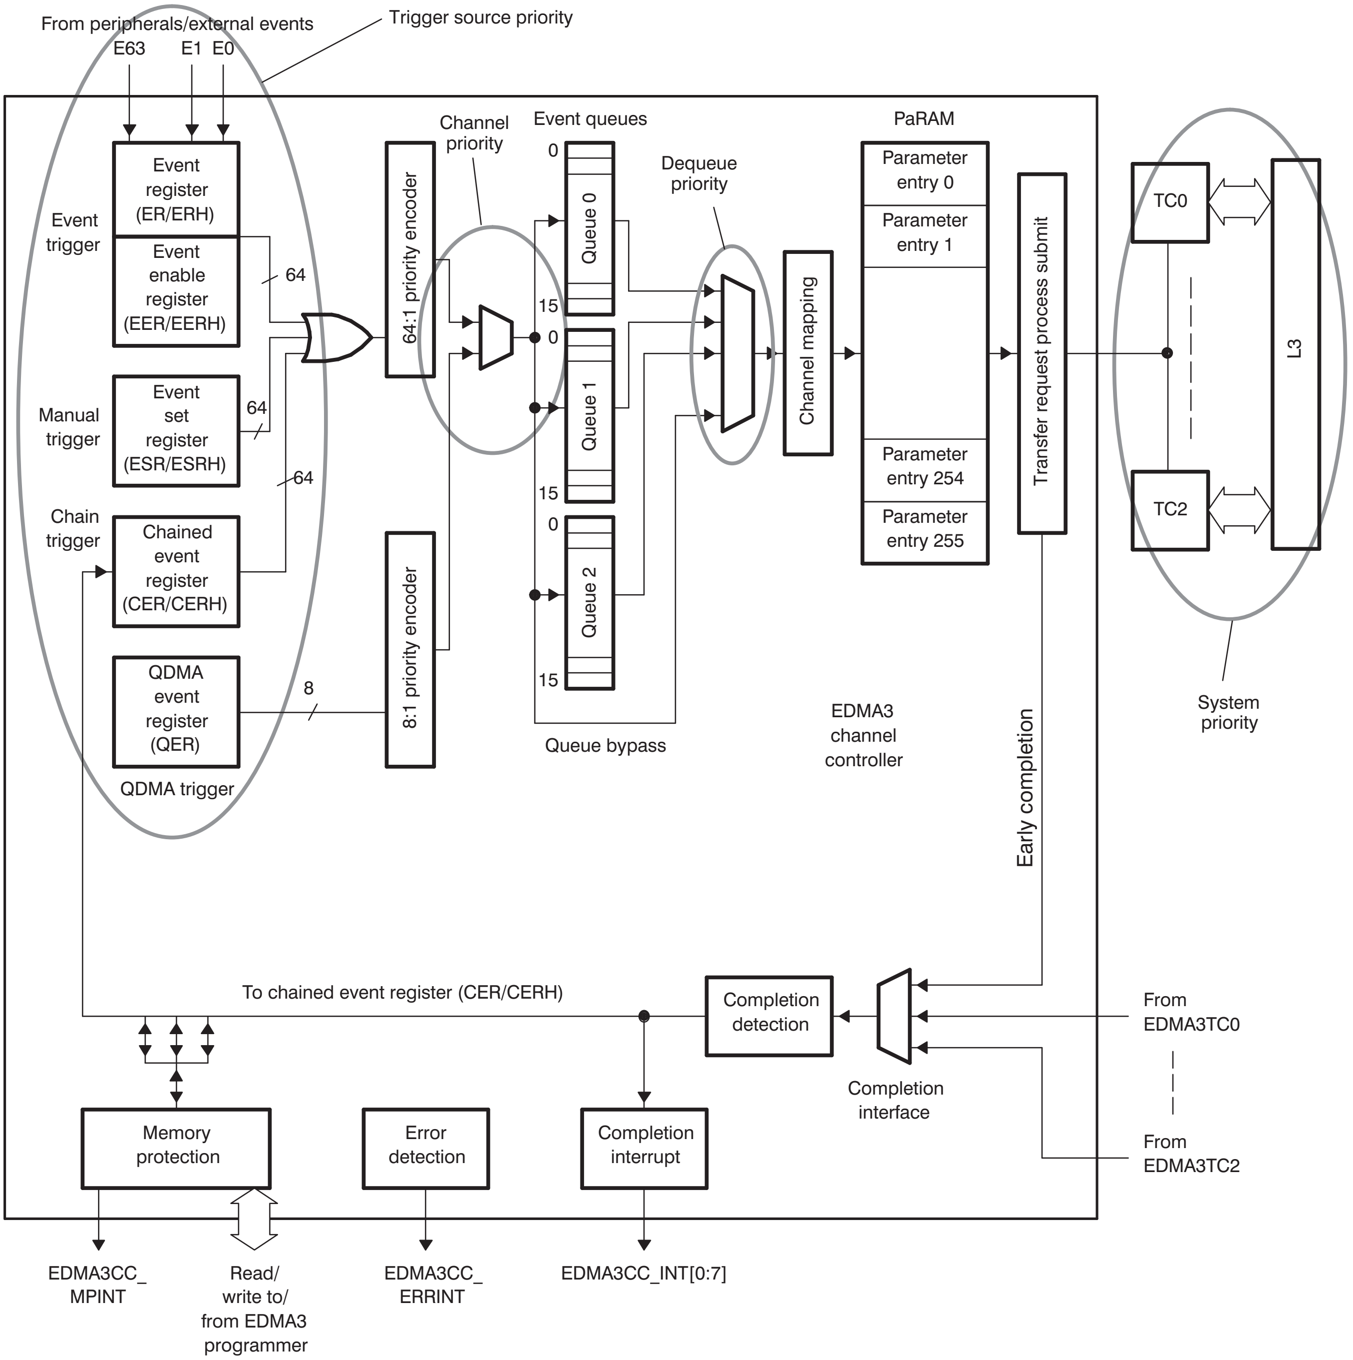
The EDMA3 controller can be idled on receiving a clock stop request from the PRCM. The requests to EDMA3CC and EDMA3TC are separate. In general, it should be verified that there are no pending activities in the EDMA3 controller

10.3.18 Emulation Considerations

During debug when using the emulator, the CPU(s) may be halted on an execute packet boundary for single-stepping, benchmarking, profiling, or other debug purposes. During an emulation halt, the EDMA3 channel controller and transfer controller operations continue. Events continue to be latched and processed and transfer requests continue to be submitted and serviced.

Since EDMA3 is involved in servicing multiple master and slave peripherals, it is not feasible to have an independent behavior of the EDMA3 for emulation halts. EDMA3 functionality would be coupled with the peripherals it is servicing, which might have different behavior during emulation halts. For example, if a McASP is halted during an emulation access (FREE = 0 and SOFT = 0 or 1 in McASP registers), the McASP stops generating the McASP receive or transmit events (REVT or XEVT) to the EDMA. From the point of view of the McASP, the EDMA3 is suspended, but other peripherals (for example, a timer) still assert events and will be serviced by the EDMA.

Figure 10-21. EDMA3 Prioritization



10.3.19 EDMA Transfer Examples

The EDMA3 channel controller performs a variety of transfers depending on the parameter configuration. The following sections provide a description and PaRAM configuration for some typical use case scenarios.

10.3.19.1 Block Move Example

The most basic transfer performed by the EDMA3 is a block move. During device operation it is often necessary to transfer a block of data from one location to another, usually between on-chip and off-chip memory.

In this example, a section of data is to be copied from external memory to internal L2 SRAM as shown in Figure 10-22. Figure 10-23 shows the parameters for this transfer.

The source address for the transfer is set to the start of the data block in external memory, and the destination address is set to the start of the data block in L2. If the data block is less than 64K bytes, the PaRAM configuration shown in Figure 10-23 holds true with the synchronization type set to A-synchronized and indexes cleared to 0. If the amount of data is greater than 64K bytes, BCNT and the B-indexes need to be set appropriately with the synchronization type set to AB-synchronized. The STATIC bit in OPT is set to prevent linking.

This transfer example may also be set up using QDMA. For successive transfer submissions, of a similar nature, the number of cycles used to submit the transfer are fewer depending on the number of changing transfer parameters. You may program the QDMA trigger word to be the highest numbered offset in the PaRAM set that undergoes change.

10.3.19.2 Subframe Extraction Example

The EDMA3 can efficiently extract a small frame of data from a larger frame of data. By performing a 2D-to-1D transfer, the EDMA3 retrieves a portion of data for the CPU to process. In this example, a 640 × 480-pixel frame of video data is stored in external memory. Each pixel is represented by a 16-bit halfword. The CPU extracts a 16 × 12-pixel subframe of the image for processing. To facilitate more efficient processing time by the CPU, the EDMA3 places the subframe in internal L2 SRAM. Figure 10-24 shows the transfer of a subframe from external memory to L2. Figure 10-25 shows the parameters for this transfer.

The same PaRAM entry options are used for QDMA channels, as well as DMA channels. The STATIC bit in OPT is set to prevent linking. For successive transfers, only changed parameters need to be programmed before triggering the channel.

10.3.19.3 Data Sorting Example

Many applications require the use of multiple data arrays; it is often desirable to have the arrays arranged such that the first elements of each array are adjacent, the second elements are adjacent, and so on. Often this is not how the data is presented to the device. Either data is transferred via a peripheral with the data arrays arriving one after the other or the arrays are located in memory with each array occupying a portion of contiguous memory spaces. For these instances, the EDMA3 can reorganize the data into the desired format. Figure 10-26 shows the data sorting.

To determine the parameter set values, the following need to be considered:

- ACNT - Program this to be the size in bytes of an element.
- BCNT - Program this to be the number of elements in a frame.
- CCNT - Program this to be the number of frames.
- SRCBIDX - Program this to be the size of the element or ACNT.
- DSTBIDX - CCNT × ACNT
- SRCCDX - ACNT × BCNT
- DSTCIDX - ACNT

The synchronization type needs to be AB-synchronized and the STATIC bit is 0 to allow updates to the parameter set. It is advised to use normal EDMA3 channels for sorting.

It is not possible to sort this with a single trigger event. Instead, the channel can be programmed to be chained to itself. After BCNT elements get sorted, intermediate chaining could be used to trigger the channel again causing the transfer of the next BCNT elements and so on. Figure 10-27 shows the parameter set programming for this transfer, assuming channel 0 and an element size of 4 bytes.

Figure 10-26. Data Sorting Example

10.3.19.4 Peripheral Servicing Example

The EDMA3 channel controller also services peripherals in the background of CPU operation, without requiring any CPU intervention. Through proper initialization of the EDMA3 channels, they can be configured to continuously service on-chip and off-chip peripherals throughout the device operation. Each event available to the EDMA3 has its own dedicated channel, and all channels operate simultaneously. The only requirements are to use the proper channel for a particular transfer and to enable the channel event in the event enable register (EER). When programming an EDMA3 channel to service a peripheral, it is necessary to know how data is to be presented to the processor. Data is always provided with some kind of synchronization event as either one element per event (non-bursting) or multiple elements per event (bursting).

10.3.19.4.1 Non-bursting Peripherals

Non-bursting peripherals include the on-chip multichannel audio serial port (McASP) and many external devices, such as codecs. Regardless of the peripheral, the EDMA3 channel configuration is the same.

The McASP transmit and receive data streams are treated independently by the EDMA3. The transmit and receive data streams can have completely different counts, data sizes, and formats. Figure 10-28 shows servicing incoming McASP data.

To transfer the incoming data stream to its proper location in DDR memory, the EDMA3 channel must be set up for a 1D-to-1D transfer with A-synchronization. Because an event (AREVT) is generated for every word as it arrives, it is necessary to have the EDMA3 issue the transfer request for each element individually. Figure 10-29 shows the parameters for this transfer. The source address of the EDMA3 channel is set to the data port address(DAT) for McASP, and the destination address is set to the start of the data block in DDR. Because the address of serializer buffer is fixed, the source B index is cleared to 0 (no modification) and the destination B index is set to 01b (increment).

Based on the premise that serial data is typically a high priority, the EDMA3 channel should be programmed to be on queue 0.

10.3.19.4.2 Bursting Peripherals

Higher bandwidth applications require that multiple data elements be presented to the processor core for every synchronization event. This frame of data can either be from multiple sources that are working simultaneously or from a single high-throughput peripheral that streams data to/from the processor.

In this example, a port is receiving a video frame from a camera and presenting it to the processor one array at a time. The video image is 640 × 480 pixels, with each pixel represented by a 16-bit element. The image is to be stored in external memory. Figure 10-30 shows this example.

To transfer data from an external peripheral to an external buffer one array at a time based on EVT*n* , channel *n* must be configured. Due to the nature of the data (a video frame made up of arrays of pixels) the destination is essentially a 2D entity. Figure 10-31 shows the parameters to service the incoming data with a 1D-to-2D transfer using AB-synchronization. The source address is set to the location of the video framer peripheral, and the destination address is set to the start of the data buffer. Because the input address is static, the SRCBIDX is 0 (no modification to the source address). The destination is made up of arrays of contiguous, linear elements; therefore, the DSTBIDX is set to pixel size, 2 bytes. ANCT is equal to the pixel size, 2 bytes. BCNT is set to the number of pixels in an array, 640. CCNT is equal to the total number of arrays in the block, 480. SRCCIDX is 0 because the source address undergoes no increment. The DSTCIDX is equal to the difference between the starting addresses of each array. Because a pixel is 16 bits (2 bytes), DSTCIDX is equal to 640 × 2.

10.3.19.4.3 Continuous Operation

Configuring an EDMA3 channel to receive a single frame of data is useful, and is applicable to some systems. A majority of the time, however, data is going to be continuously transmitted and received throughout the entire operation of the processor. In this case, it is necessary to implement some form of linking such that the EDMA3 channels continuously reload the necessary parameter sets. In this example, McASP is configured to transmit and receive data on a T1 array. To simplify the example, only two channels are active for both transmit and receive data streams. Each channel receives packets of 128 elements. The packets are transferred from the serial port to internal memory and from internal memory to the serial port, as shown Figure 10-32.

The McASP generates AREVT for every element received and generates AXEVT for every element transmitted. To service the data streams, the DMA channels associated with the McASP must be setup for 1D-to-1D transfers with A-synchronization.

Figure 10-33 shows the parameter entries for the channel for these transfers. To service the McASP continuously, the channels must be linked to a duplicate PaRAM set in the PaRAM. After all frames have been transferred, the EDMA3 channels reload and continue. Figure 10-34 shows the reload parameters for the channel.

10.3.19.4.3.1 Receive Channel

EDMA3 channel 15 services the incoming data stream of McASP. The source address is set to that of the receive serializer buffer, and the destination address is set to the first element of the data block. Because there are two data channels being serviced, A and B, they are to be located separately within the L2 SRAM.

To facilitate continuous operation, a copy of the PaRAM set for the channel is placed in PaRAM set 64. The LINK option is set and the link address is provided in the PaRAM set. Upon exhausting the channel 15 parameter set, the parameters located at the link address are loaded into the channel 15 parameter set and operation continues. This function continues throughout device operation until halted by the CPU.

10.3.19.4.3.2 Transmit Channel

EDMA3 channel 12 services the outgoing data stream of McASP. In this case the destination address needs no update, hence, the parameter set changes accordingly. Linking is also used to allow continuous operation by the EDMA3 channel, with duplicate PaRAM set entries at PaRAM set 65.

10.3.19.4.4 Ping-Pong Buffering

Although the previous configuration allows the EDMA3 to service a peripheral continuously, it presents a number of restrictions to the CPU. Because the input and output buffers are continuously being filled/emptied, the CPU must match the pace of the EDMA3 very closely to process the data. The EDMA3 receive data must always be placed in memory before the CPU accesses it, and the CPU must provide the output data before the EDMA3 transfers it. Though not impossible, this is an unnecessary challenge. It is particularly difficult in a 2-level cache scheme.

Ping-pong buffering is a simple technique that allows the CPU activity to be distanced from the EDMA3 activity. This means that there are multiple (usually two) sets of data buffers for all incoming and outgoing data streams. While the EDMA3 transfers the data into and out of the ping buffers, the CPU manipulates the data in the pong buffers. When both CPU and EDMA3 activity completes, they switch. The EDMA3 then writes over the old input data and transfers the new output data. Figure 10-35 shows the ping-pong scheme for this example.

To change the continuous operation example, such that a ping-pong buffering scheme is used, the EDMA3 channels need only a moderate change. Instead of one parameter set, there are two; one for transferring data to/from the ping buffers and one for transferring data to/from the pong buffers. As soon as one transfer completes, the channel loads the PaRAM set for the other and the data transfers continue. Figure 10-36 shows the EDMA3 channel configuration required.

Each channel has two parameter sets, ping and pong. The EDMA3 channel is initially loaded with the ping parameters (Figure 10-36). The link address for the ping set is set to the PaRAM offset of the pong parameter set (Figure 10-37). The link address for the pong set is set to the PaRAM offset of the ping parameter set (Figure 10-38). The channel options, count values, and index values are all identical between the ping and pong parameters for each channel. The only differences are the link address provided and the address of the data buffer.

10.3.19.4.4.1 Synchronization with the CPU

To utilize the ping-pong buffering technique, the system must signal the CPU when to begin to access the new data set. After the CPU finishes processing an input buffer (ping), it waits for the EDMA3 to complete before switching to the alternate (pong) buffer. In this example, both channels provide their channel numbers as their report word and set the TCINTEN bit to generate an interrupt after completion. When channel 15 fills an input buffer, the E15 bit in the interrupt pending register (IPR) is set; when channel 12 empties an output buffer, the E12 bit in IPR is set. The CPU must manually clear these bits. With the channel parameters set, the CPU polls IPR to determine when to switch. The EDMA3 and CPU could alternatively be configured such that the channel completion interrupts the CPU. By doing this, the CPU could service a background task while waiting for the EDMA3 to complete.

10.3.19.4.5 Transfer Chaining Examples

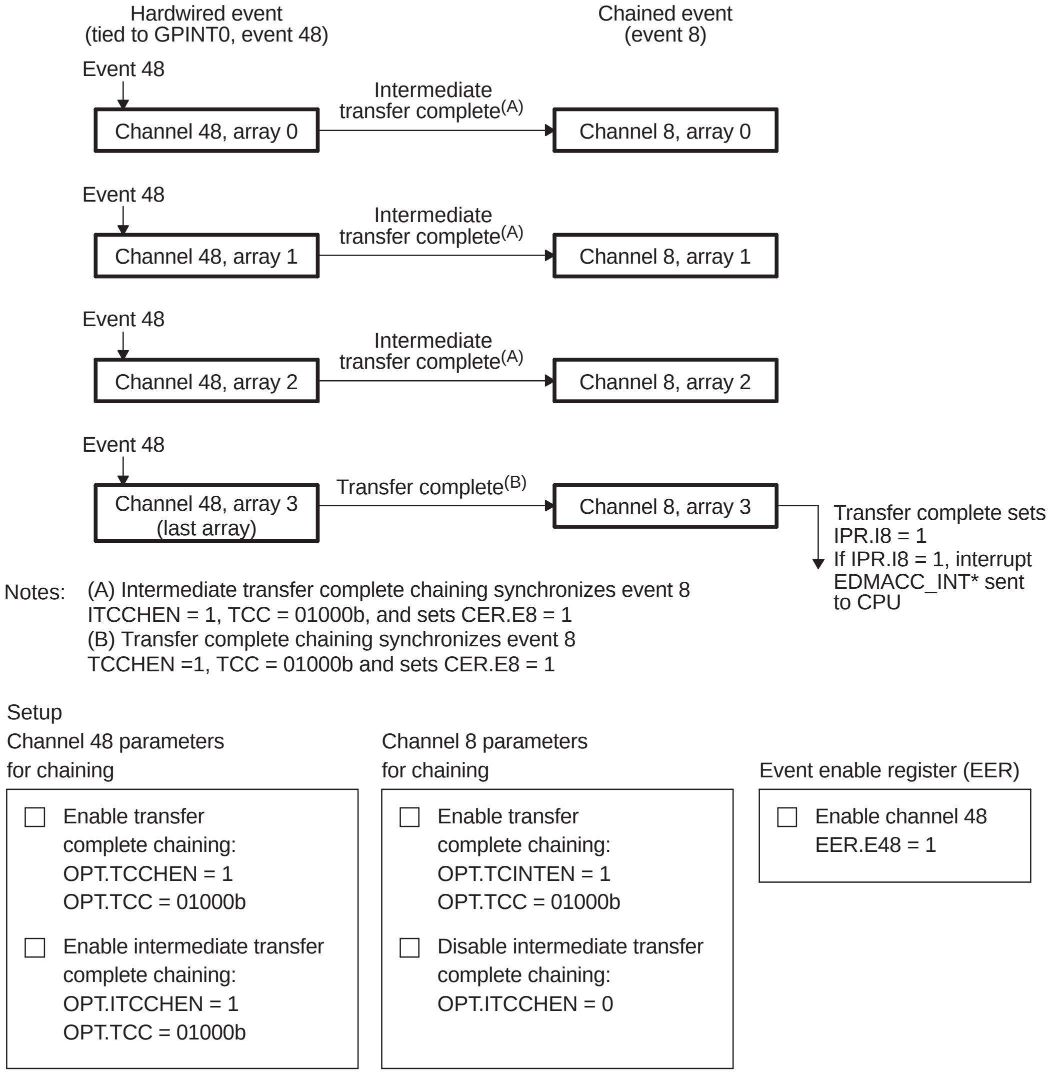
The following examples explain the intermediate transfer complete chaining function.

10.3.19.4.5.1 Servicing Input/Output FIFOs with a Single Event

Many systems require the use of a pair of external FIFOs that must be serviced at the same rate. One FIFO buffers data input, and the other buffers data output. The EDMA3 channels that service these FIFOs can be set up for AB-synchronized transfers. While each FIFO is serviced with a different set of parameters, both can be signaled from a single event. For example, an external interrupt pin can be tied to the status flags of one of the FIFOs. When this event arrives, the EDMA3 needs to perform servicing for both the input and output streams. Without the intermediate transfer complete chaining feature this would require two events, and thus two external interrupt pins. The intermediate transfer complete chaining feature allows the use of a single external event (for example, a GPIO event). Figure 10-39 shows the EDMA3 setup and illustration for this example.

A GPIO event (in this case, GPINT0) triggers an array transfer. Upon completion of each intermediate array transfer of channel 48, intermediate transfer complete chaining sets the E8 bit (specified by TCC of 8) in the chained event register (CER) and provides a synchronization event to channel 8. Upon completion of the last array transfer of channel 48, transfer complete chaining—not intermediate transfer complete chaining—sets the E8 bit in CER (specified by TCCMODE:TCC) and provides a synchronization event to channel 8. The completion of channel 8 sets the I8 bit (specified by TCCMODE:TCC) in the interrupt pending register (IPR), which can generate an interrupt to the CPU, if the I8 bit in the interrupt enable register (IER) is set.

Figure 10-39. Intermediate Transfer Completion Chaining Example



Notes: (A) Intermediate transfer complete chaining synchronizes event 8
ITCCHEN = 1, TCC = 01000b, and sets CER.E8 = 1
(B) Transfer complete chaining synchronizes event 8
TCCHEN =1, TCC = 01000b and sets CER.E8 = 1

Setup

Channel 48 parameters for chaining

☐ Enable transfer complete chaining:
OPT.TCCHEN = 1
OPT.TCC = 01000b

☐ Enable intermediate transfer complete chaining:
OPT.ITCCHEN = 1
OPT.TCC = 01000b

Channel 8 parameters for chaining

☐ Enable transfer complete chaining:
OPT.TCINTEN = 1
OPT.TCC = 01000b

☐ Disable intermediate transfer complete chaining:
OPT.ITCCHEN = 0

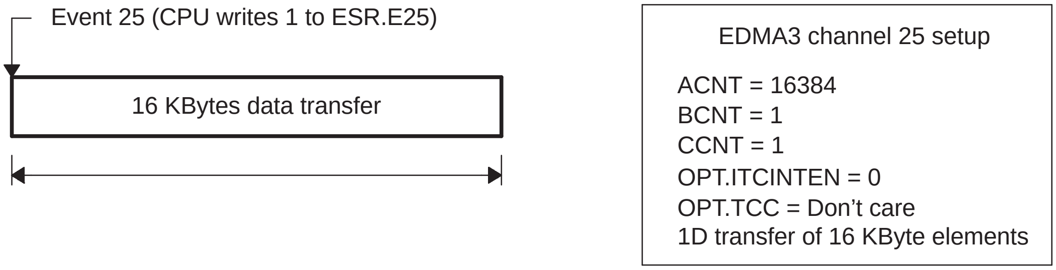
Event enable register (EER)

☐ Enable channel 48
EER.E48 = 1

10.3.19.4.5.2 Breaking Up Large Transfers with Intermediate Chaining

Another feature of intermediate transfer chaining (ITCCHEN) is for breaking up large transfers. A large transfer may lock out other transfers of the same priority level for the duration of the transfer. For example, a large transfer on queue 0 from the internal memory to the external memory using the EMIF may starve other EDMA3 transfers on the same queue. In addition, this large high-priority transfer may prevent the EMIF for a long duration to service other lower priority transfers. When a large transfer is considered to be high priority, it should be split into multiple smaller transfers. Figure 10-40 shows the EDMA3 setup and illustration of an example single large block transfer.

Figure 10-40. Single Large Block Transfer Example

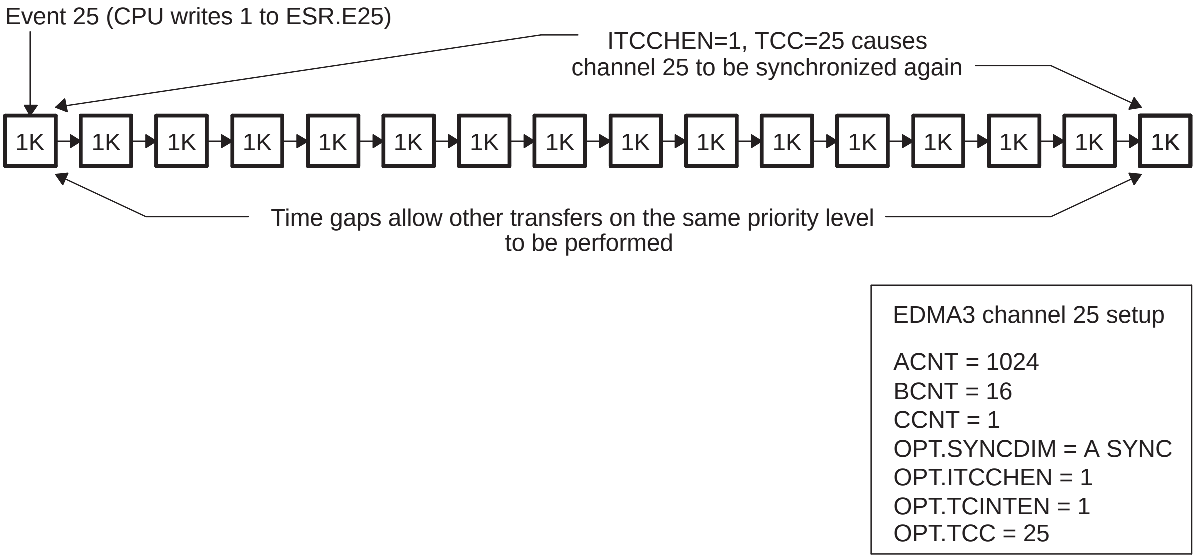


EDMA3 channel 25 setup

ACNT = 16384
BCNT = 1
CCNT = 1
OPT.ITCINTEN = 0
OPT.TCC = Don’t care
1D transfer of 16 KByte elements

The intermediate transfer chaining enable (ITCCHEN) provides a method to break up a large transfer into smaller transfers. For example, to move a single large block of memory (16K bytes), the EDMA3 performs an A-synchronized transfer. The element count is set to a reasonable value, where reasonable derives from the amount of time it would take to move this smaller amount of data. Assume 1 Kbyte is a reasonable small transfer in this example. The EDMA3 is set up to transfer 16 arrays of 1 Kbyte elements, for a total of 16K byte elements. The TCC field in the channel options parameter (OPT) is set to the same value as the channel number and ITCCHEN are set. In this example, EDMA3 channel 25 is used and TCC is also set to 25. The TCINTEN may also be set to trigger interrupt 25 when the last 1 Kbyte array is transferred. The CPU starts the EDMA3 transfer by writing to the appropriate bit of the event set register (ESR.E25). The EDMA3 transfers the first 1 Kbyte array. Upon completion of the first array, intermediate transfer complete code chaining generates a synchronization event to channel 25, a value specified by the TCC field. This intermediate transfer completion chaining event causes EDMA3 channel 25 to transfer the next 1 Kbyte array. This process continues until the transfer parameters are exhausted, at which point the EDMA3 has completed the 16K byte transfer. This method breaks up a large transfer into smaller packets, thus providing natural time slices in the transfer such that other events may be processed. Figure 10-41 shows the EDMA3 setup and illustration of the broken up smaller packet transfers.

Figure 10-41. Smaller Packet Data Transfers Example



EDMA3 channel 25 setup

ACNT = 1024
BCNT = 16
CCNT = 1
OPT.SYNCDIM = A SYNC
OPT.ITCCHEN = 1
OPT.TCINTEN = 1
OPT.TCC = 25

Table 10-28. SYSCONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	
5-4	RESERVED	R	0h	
3-2	IDLEMODE	R/W	2h	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0h (R/W) = Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, i.e. regardless of the IP module's internal requirements. Backup mode, for debug only. 1h (R/W) = No-idle mode: local target never enters idle state. Backup mode, for debug only. 2h (R/W) = Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wakeup events. 3h (R/W) = Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state. Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented.

4-0	RESERVED	R	0h	

10.4.1.5 QCHMAP_0 to QCHMAP_7 Register (Offset = 200h to 21Ch) [reset = 0h]

QCHMAP_0 to QCHMAP_7 is shown in Figure 10-46 and described in Table 10-30.

Return to Summary Table.

Each QDMA channel in EDMA3CC can be associated with any PaRAM set available on the device. Furthermore, the specific trigger word (0-7) of the PaRAM set can be programmed. The PaRAM set association and trigger word for every QDMA channel register is configurable using the QDMA channel map register (QCHMAPn). At reset the QDMA channel map registers for all QDMA channels point to PaRAM set 0. If an application makes use of both a DMA channel that points to PaRAM set 0 and any QDMA channels, ensure that QCHMAP is programmed appropriately to point to a different PaRAM entry.

Bit	Field	Type	Reset	Description
31-14	RESERVED	R	0h	
13-5	PAENTRY	R/W	0h	PAENTRY points to the PaRAM set number for QDMA channel . 0h (R/W) = Parameter entry 0 through 255, from 0 to FFh. 1h (R/W) = Reserved, from 100h to 1FFh. Always write 0 to this bit. Writes of 1 to this bit are not supported and attempts to do so may result in undefine behavior.
4-2	TRWORD	R/W	0h	Points to the specific trigger word of the PaRAM set defined by PAENTRY. A write to the trigger word results in a QDMA event being recognized.
1-0	RESERVED	R	0h	

10.4.1.6 DMAQNUM_0 to DMAQNUM_7 Register (Offset = 240h to 25Ch) [reset = 0h]

DMAQNUM_0 to DMAQNUM_7 is shown in Figure 10-47 and described in Table 10-31.

Return to Summary Table.

The DMA channel queue number register (DMAQNUMn) allows programmability of each of the 64 DMA channels in the EDMA3CC to submit its associated synchronization event to any event queue in the EDMA3CC. At reset, all channels point to event queue 0. Because the event queues in EDMA3CC have a fixed association to the transfer controllers, that is, Q0 TRs are submitted to TC0, Q1 TRs are submitted to TC1, etc., by programming DMAQNUM for a particular DMA channel also dictates which transfer controller is utilized for the data movement (or which EDMA3TC receives the TR request).

10.4.1.8 QUEPRI Register (Offset = 284h) [reset = 777h]

QUEPRI is shown in Figure 10-49 and described in Table 10-33.

Return to Summary Table.

The queue priority register (QUEPRI) allows you to change the priority of the individual queues and the priority of the transfer request (TR) associated with the events queued in the queue. Because the queue to EDMA3TC mapping is fixed, programming QUEPRI essentially governs the priority of the associated transfer controller(s) read/write commands with respect to the other bus masters in the device. You can modify the EDMA3TC priority to obtain the desired system performance.

6-4	PRIQ1	R/W	7h	Priority level for queue 1. Dictates the priority level used by TC1 relative to other masters in the device. A value of 0 means highest priority and a value of 7 means lowest priority.
3	RESERVED	R	0h	
2-0	PRIQ0	R/W	7h	Priority level for queue 0. Dictates the priority level used by TC0 relative to other masters in the device. A value of 0 means highest priority and a value of 7 means lowest priority.

10.4.1.9 EMR Register (Offset = 300h) [reset = 0h]

EMR is shown in Figure 10-50 and described in Table 10-34.

Return to Summary Table.

For a particular DMA channel, if a second event is received prior to the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the event missed registers (EMR/EMRH). All trigger types are treated individually, that is, manual triggered (ESR/ESRH), chain triggered (CER/CERH), and event triggered (ER/ERH) are all treated separately. The EMR/EMRH bits for a channel are also set if an event on that channel encounters a NULL entry (or a NULL TR is serviced). If any EMR/EMRH bit is set (and all errors, including bits in other error registers (QEMR, CCERR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see Error Interrupts. This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

Bit	Field	Type	Reset	Description
31-0	En	R	0h	Channel 0 to 31 event missed. En is cleared by writing a 1 to the corresponding bit in the event missed clear register (EMCR). 0h (R/W) = No missed event. 1h (R/W) = Missed event occurred.

10.4.1.10 EMRH Register (Offset = 304h) [reset = 0h]

EMRH is shown in Figure 10-51 and described in Table 10-35.

Return to Summary Table.

For a particular DMA channel, if a second event is received prior to the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the event missed registers (EMR/EMRH). All trigger types are treated individually, that is, manual triggered (ESR/ESRH), chain triggered (CER/CERH), and event triggered (ER/ERH) are all treated separately. The EMR/EMRH bits for a channel are also set if an event on that channel encounters a NULL entry (or a NULL TR is serviced). If any EMR/EMRH bit is set (and all errors, including bits in other error registers (QEMR, CCERR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see Error Interrupts. This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

Bit	Field	Type	Reset	Description
31-0	En	R	0h	Channel 32 to 63 event missed. En is cleared by writing a 1 to the corresponding bit in the event missed clear register high (EMCRH). 0h (R/W) = No missed event. 1h (R/W) = Missed event occurred.

10.4.1.11 EMCR Register (Offset = 308h) [reset = 0h]

EMCR is shown in Figure 10-52 and described in Table 10-36.

Return to Summary Table.

Once a missed event is posted in the event missed registers (EMR/EMRH), the bit remains set and you need to clear the set bit(s). This is done by way of CPU writes to the event missed clear registers (EMCR/EMCRH). Writing a 1 to any of the bits clears the corresponding missed event (bit) in EMR/EMRH; writing a 0 has no effect. This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

10.4.1.13 QEMR Register (Offset = 310h) [reset = 0h]

QEMR is shown in Figure 10-54 and described in Table 10-38.

Return to Summary Table.

For a particular QDMA channel, if two QDMA events are detected without the first event getting cleared/serviced, the bit corresponding to that channel is set/asserted in the QDMA event missed register (QEMR). The QEMR bits for a channel are also set if a QDMA event on the channel encounters a NULL entry (or a NULL TR is serviced). If any QEMR bit is set (and all errors, including bits in other error registers (EMR/EMRH, CCERR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see Error Interrupts. This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

10.4.1.15 CCERR Register (Offset = 318h) [reset = 0h]

CCERR is shown in Figure 10-56 and described in Table 10-40.

Return to Summary Table.

The EDMA3CC error register (CCERR) indicates whether or not at any instant of time the number of events queued up in any of the event queues exceeds or equals the threshold/watermark value that is set in the queue watermark threshold register (QWMTHRA). Additionally, CCERR also indicates if when the number of outstanding TRs that have been programmed to return transfer completion code (TRs which have the TCINTEN or TCCHEN bit in OPT set) to the EDMA3CC has exceeded the maximum allowed value of 63. If any bit in CCERR is set (and all errors, including bits in other error registers (EMR/EMRH, QEMR) were previously cleared), the EDMA3CC generates an error interrupt. For details on EDMA3CC error interrupt generation, see Error Interrupts. Once the error bits are set in CCERR, they can only be cleared by writing to the corresponding bits in the EDMA3CC error clear register (CCERRCLR). This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

10.4.1.16 CCERRCLR Register (Offset = 31Ch) [reset = 0h]

CCERRCLR is shown in Figure 10-57 and described in Table 10-41.

Return to Summary Table.

The EDMA3CC error clear register (CCERRCLR) is used to clear any error bits that are set in the EDMA3CC error register (CCERR). In addition, CCERRCLR also clears the values of some bit fields in the queue status registers (QSTATn) associated with a particular event queue. Writing a 1 to any of the bits clears the corresponding bit in CCERR; writing a 0 has no effect. This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

10.4.1.17 EEVAL Register (Offset = 320h) [reset = 0h]

EEVAL is shown in Figure 10-58 and described in Table 10-42.

Return to Summary Table.

The EDMA3CC error interrupt is asserted whenever an error bit is set in any of the error registers (EMR/EMRH, QEMR, and CCERR). For subsequent error bits that get set, the EDMA3CC error interrupt is reasserted only when transitioning from an all the error bits cleared to at least one error bit is set . Alternatively, a CPU write of 1 to the EVAL bit in the error evaluation register (EEVAL) results in reasserting the EDMA3CC error interrupt, if there are any outstanding error bits set due to subsequent error conditions. Writes of 0 have no effect. This register is part of a set of registers that provide information on missed DMA and/or QDMA events, and instances when event queue thresholds are exceeded. If any of the bits in these registers is set, it results in the EDMA3CC generating an error interrupt.

Reads return 0 on bit n and writes do not modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 do not contribute to the generation of a transfer completion interrupt for shadow region 2. 1h (R/W) = Accesses via region 2 address space to bit 63 to 32 in any DMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit 63 to 32. Enabled interrupt bits for bit 31 to 0 contribute to the generation of a transfer completion interrupt for shadow region 2.

10.4.1.24 DRAE3 Register (Offset = 358h) [reset = 0h]

DRAE3 is shown in Figure 10-65 and described in Table 10-49.

Return to Summary Table.

The DMA region access enable register for shadow region 3 is programmed to allow or disallow read/write accesses on a bit-by-bit bases for all DMA registers in the shadow region 3 view of the DMA channel registers. Additionally, the DRAE3 configuration determines completion of which DMA channels will result in assertion of the shadow region 3 DMA completion interrupt. The DRAE registers are part of the group of the region access enable registers, which includes DRAEm and QRAEm. Where m is the number of shadow regions in the EDMA3CC memory map for a device. You can configure these registers to assign ownership of DMA/QDMA channels to a particular shadow region.

Reads return 0 on bit n and writes do not modify the state of bit n. 1h (R/W) = Accesses via region m address space to bit n in any QDMA channel register are allowed. Reads return the value from bit n and writes modify the state of bit n.

10.4.1.27 Q0E_0 to Q0E_15 Register (Offset = 400h to 43Ch) [reset = 0h]

Q0E_0 to Q0E_15 is shown in Figure 10-68 and described in Table 10-52.

Return to Summary Table.

The event queue entry registers (QxEy) exist for all 16 queue entries (the maximum allowed queue entries) for all event queues in the EDMA3CC. The event queue entry registers range from Q0E0 to Q0E15, Q1E0 to Q1E15, and Q2E0 to Q2E15. Each register details the event number (ENUM) and the event type (ETYPE). For example, if the value in Q1E4 is read as 000 004Fh, this means the 4th entry in queue 1 is a manually-triggered event on DMA channel 15. The Q0E0 register provides visibility into the event queues and a TR life cycle. These are useful for system debug as they provide in-depth visibility for the events queued up in the event queue and also provide information on what parts of the EDMA3CC logic are active once the event has been received by the EDMA3CC.

10.4.1.38 ER Register (Offset = 1000h) [reset = 0h]

ER is shown in Figure 10-79 and described in Table 10-63.

Return to Summary Table.

All external events are captured in the event register (ER/ERH). The events are latched even when the events are not enabled. If the event bit corresponding to the latched event is enabled (EER.En/EERH.En = 1), then the event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. The event register bits are automatically cleared (ER.En/ERH.En= 0) once the corresponding events are prioritized and serviced. If ER.En/ERH.En are already set and another event is received on the same channel/event, then the corresponding event is latched in the event miss register (EMR.En/EMRH.En), provided that the event was enabled (EER.En/EERH.En = 1). Event n can be cleared by the CPU writing a 1 to corresponding event bit in the event clear register (ECR/ECRH). The setting of an event is a higher priority relative to clear operations (via hardware or software). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues. The Debug List table provides the type of synchronization events and the EDMA3CC channels associated to each of these external events. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg_name that corresponds to DMA channels 0 through 31 and reg_name_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

Bit	Field	Type	Reset	Description
31-0	En	R	0h	Event 0 to 31. Events 0 to 31 are captured by the EDMA3CC and are latched into ER. The events are set (En = 1) even when events are disabled (En = 0 in the event enable register, EER). 0h (R/W) = EDMA3CC event is not asserted. 1h (R/W) = EDMA3CC event is asserted. Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.

10.4.1.39 ERH Register (Offset = 1004h) [reset = 0h]

ERH is shown in Figure 10-80 and described in Table 10-64.

Return to Summary Table.

All external events are captured in the event register (ER/ERH). The events are latched even when the events are not enabled. If the event bit corresponding to the latched event is enabled (EER.En/EERH.En = 1), then the event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. The event register bits are automatically cleared (ER.En/ERH.En= 0) once the corresponding events are prioritized and serviced. If ER.En/ERH.En are already set and another event is received on the same channel/event, then the corresponding event is latched in the event miss register (EMR.En/EMRH.En), provided that the event was enabled (EER.En/EERH.En = 1). Event n can be cleared by the CPU writing a 1 to corresponding event bit in the event clear register (ECR/ECRH). The setting of an event is a higher priority relative to clear operations (via hardware or software). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues. The Debug List table provides the type of synchronization events and the EDMA3CC channels associated to each of these external events. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg_name that corresponds to DMA channels 0 through 31 and reg_name_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

Bit	Field	Type	Reset	Description
31-0	En	R	0h	Event 32 to 63. Events 32 to 63 are captured by the EDMA3CC and are latched into ERH. The events are set (En = 1) even when events are disabled (En = 0 in the event enable register high, EERH). 0h (R/W) = EDMA3CC event is not asserted. 1h (R/W) = EDMA3CC event is asserted. Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.

10.4.1.40 ECR Register (Offset = 1008h) [reset = 0h]

ECR is shown in Figure 10-81 and described in Table 10-65.

Return to Summary Table.

Once an event has been posted in the event registers (ER/ERH), the event is cleared in two ways. If the event is enabled in the event enable register (EER/EERH) and the EDMA3CC submits a transfer request for the event to the EDMA3TC, it clears the corresponding event bit in the event register. If the event is disabled in the event enable register (EER/EERH), the CPU can clear the event by way of the event clear registers (ECR/ECRH). Writing a 1 to any of the bits clears the corresponding event; writing a 0 has no effect. Once an event bit is set in the event register, it remains set until EDMA3CC submits a transfer request for that event or the CPU clears the event by setting the corresponding bit in ECR/ECRH. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg_name that corresponds to DMA channels 0 through 31 and reg_name_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

Bit	Field	Type	Reset	Description
31-0	En	W	0h	Event clear for event 0 to 31. Any of the event bits in ECR is set to clear the event (En) in the event register (ER). A write of 0 has no effect. 0h (R/W) = No effect. 1h (R/W) = EDMA3CC event is cleared in the event register (ER).

10.4.1.41 ECRH Register (Offset = 100Ch) [reset = 0h]

ECRH is shown in Figure 10-82 and described in Table 10-66.

Return to Summary Table.

Once an event has been posted in the event registers (ER/ERH), the event is cleared in two ways. If the event is enabled in the event enable register (EER/EERH) and the EDMA3CC submits a transfer request for the event to the EDMA3TC, it clears the corresponding event bit in the event register. If the event is disabled in the event enable register (EER/EERH), the CPU can clear the event by way of the event clear registers (ECR/ECRH). Writing a 1 to any of the bits clears the corresponding event; writing a 0 has no effect. Once an event bit is set in the event register, it remains set until EDMA3CC submits a transfer request for that event or the CPU clears the event by setting the corresponding bit in ECR/ECRH. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg_name that corresponds to DMA channels 0 through 31 and reg_name_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

Table 10-66. ECRH Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	En	W	0h	Event clear for event 32 to 63. Any of the event bits in ECRH are set to clear the event (En) in the event register high (ERH). A write of 0 has no effect. 0h (R/W) = No effect. 1h (R/W) = EDMA3CC event is cleared in the event register high (ERH).

10.4.1.42 ESR Register (Offset = 1010h) [reset = 0h]

ESR is shown in Figure 10-83 and described in Table 10-67.

Return to Summary Table.

The event set registers (ESR/ESRH) allow the CPU (EDMA3 programmers) to manually set events to initiate DMA transfer requests. CPU writes of 1 to any event set register (En) bits set the corresponding bits in the registers. The set event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. Writing a 0 has no effect. The event set registers operate independent of the event registers (ER/ERH), and a write of 1 is always considered a valid event regardless of whether the event is enabled (the corresponding event bits are set or cleared in EER.En/EERH.En). Once the event is set in the event set registers, it cannot be cleared by CPU writes, in other words, the event clear registers (ECR/ECRH) have no effect on the state of ESR/ESRH. The bits will only be cleared once the transfer request corresponding to the event has been submitted to the transfer controller. The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues. Manually-triggered transfers via writes to ESR/ESRH allow the CPU to submit DMA requests in the system, these are relevant for memory-to-memory transfer scenarios. If the ESR.En/ESRH.En bit is already set and another CPU write of 1 is attempted to the same bit, then the corresponding event is latched in the event missed registers (EMR.En/EMRH.En = 1). This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg_name that corresponds to DMA channels 0 through 31 and reg_name_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

10.4.1.43 ESRH Register (Offset = 1014h) [reset = 0h]

ESRH is shown in Figure 10-84 and described in Table 10-68.

Return to Summary Table.

The event set registers (ESR/ESRH) allow the CPU (EDMA3 programmers) to manually set events to initiate DMA transfer requests. CPU writes of 1 to any event set register (En) bits set the corresponding bits in the registers. The set event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. Writing a 0 has no effect. The event set registers operate independent of the event registers (ER/ERH), and a write of 1 is always considered a valid event regardless of whether the event is enabled (the corresponding event bits are set or cleared in EER.En/EERH.En). Once the event is set in the event set registers, it cannot be cleared by CPU writes, in other words, the event clear registers (ECR/ECRH) have no effect on the state of ESR/ESRH. The bits will only be cleared once the transfer request corresponding to the event has been submitted to the transfer controller. The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues. Manually-triggered transfers via writes to ESR/ESRH allow the CPU to submit DMA requests in the system, these are relevant for memory-to-memory transfer scenarios. If the ESR.En/ESRH.En bit is already set and another CPU write of 1 is attempted to the same bit, then the corresponding event is latched in the event missed registers (EMR.En/EMRH.En = 1). This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg_name that corresponds to DMA channels 0 through 31 and reg_name_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

31-0	En	R/W	0h	Event set for event 32 to 63. 0h (R/W) = No effect. 1h (R/W) = Corresponding DMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.

10.4.1.44 CER Register (Offset = 1018h) [reset = 0h]

CER is shown in Figure 10-85 and described in Table 10-69.

Return to Summary Table.

When the OPTIONS parameter for a PaRAM entry is programmed to returned a chained completion code (ITCCHEN = 1 and/or TCCHEN = 1), then the value dictated by the TCC[5:0] (also programmed in OPT) forces the corresponding event bit to be set in the chained event registers (CER/CERH). The set chained event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. This results in a chained-triggered transfer. The chained event registers do not have any enables. The generation of a chained event is essentially enabled by the PaRAM entry that has been configured for intermediate and/or final chaining on transfer completion. The En bit is set (regardless of the state of EER.En/EERH.En) when a chained completion code is returned from one of the transfer controllers or is generated by the EDMA3CC via the early completion path. The bits in the chained event register are cleared when the corresponding events are prioritized and serviced. If the En bit is already set and another chaining completion code is return for the same event, then the corresponding event is latched in the event missed registers (EMR.En/EMRH.En= 1). The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg_name that corresponds to DMA channels 0 through 31 and reg_name_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

10.4.1.45 CERH Register (Offset = 101Ch) [reset = 0h]

CERH is shown in Figure 10-86 and described in Table 10-70.

Return to Summary Table.

When the OPTIONS parameter for a PaRAM entry is programmed to returned a chained completion code (ITCCHEN = 1 and/or TCCHEN = 1), then the value dictated by the TCC[5:0] (also programmed in OPT) forces the corresponding event bit to be set in the chained event registers (CER/CERH). The set chained event is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. This results in a chained-triggered transfer. The chained event registers do not have any enables. The generation of a chained event is essentially enabled by the PaRAM entry that has been configured for intermediate and/or final chaining on transfer completion. The En bit is set (regardless of the state of EER.En/EERH.En) when a chained completion code is returned from one of the transfer controllers or is generated by the EDMA3CC via the early completion path. The bits in the chained event register are cleared when the corresponding events are prioritized and serviced. If the En bit is already set and another chaining completion code is return for the same event, then the corresponding event is latched in the event missed registers (EMR.En/EMRH.En= 1). The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then EMR/EMRH would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg_name that corresponds to DMA channels 0 through 31 and reg_name_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

10.4.1.46 EER Register (Offset = 1020h) [reset = 0h]

EER is shown in Figure 10-87 and described in Table 10-71.

Return to Summary Table.

The EDMA3CC provides the option of selectively enabling/disabling each event in the event registers (ER/ERH) by using the event enable registers (EER/EERH). If an event bit in EER/EERH is set (using the event enable set registers, EESR/EESRH), it will enable that corresponding event. Alternatively, if an event bit in EER/EERH is cleared (using the event enable clear registers, EECR/EECRH), it will disable the corresponding event. The event registers latch all events that are captured by EDMA3CC, even if the events are disabled (although EDMA3CC does not process it). Enabling an event with a pending event already set in the event registers enables the EDMA3CC to process the already set event like any other new event. The EER/EERH settings do not have any effect on chained events (CER.En/CERH.En= 1) and manually set events (ESR.En/ESRH.En= 1). This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg_name that corresponds to DMA channels 0 through 31 and reg_name_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

10.4.1.52 SER Register (Offset = 1038h) [reset = 0h]

SER is shown in Figure 10-93 and described in Table 10-77.

Return to Summary Table.

The secondary event registers (SER/SERH) provide information on the state of a DMA channel or event (0 through 63). If the EDMA3CC receives a TR synchronization due to a manual-trigger, event-trigger, or chained-trigger source (ESR.En/ESRH.En= 1, ER.En/ERH.En= 1, or CER.En/CERH.En= 1), which results in the setting of a corresponding event bit in SER/SERH (SER.En/SERH.En = 1), it implies that the corresponding DMA event is in the queue. Once a bit corresponding to an event is set in SER/SERH, the EDMA3CC does not prioritize additional events on the same DMA channel. Depending on the condition that lead to the setting of the SER bits, either the EDMA3CC hardware or the software (using SECR/SECRH) needs to clear the SER/SERH bits for the EDMA3CC to evaluate subsequent events (subsequent transfers) on the same channel. For additional conditions that can cause the secondary event registers to be set, see EDMA Overview. This register is part of a set of registers that pertain to the 64 DMA channels. The 64 DMA channels consist of a set of registers (with exception of DMAQNUMn) that each have 64 bits and the bit position of each register matches the DMA channel number. Each register is named with the format reg_name that corresponds to DMA channels 0 through 31 and reg_name_High that corresponds to DMA channels 32 through 64. For example, the event register (ER) corresponds to DMA channel 0 through 31 and the event register high register (ERH) corresponds to DMA channel 32 through 63. The register is typically called the event register. The DMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write ability to the registers in the shadow region are controlled by the DMA region access registers (DRAEm/DRAEHm).

10.4.1.56 IER Register (Offset = 1050h) [reset = 0h]

IER is shown in Figure 10-97 and described in Table 10-81.

Return to Summary Table.

Interrupt enable registers (IER/IERH) are used to enable/disable the transfer completion interrupt generation by the EDMA3CC for all DMA/QDMA channels. The IER/IERH cannot be written to directly. To set any interrupt bit in IER/IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable set registers (IESR/IESRH). Similarly, to clear any interrupt bit in IER/IERH, a 1 must be written to the corresponding interrupt bit in the interrupt enable clear registers (IECR/IECRH). All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

10.4.1.58 IECR Register (Offset = 1058h) [reset = 0h]

IECR is shown in Figure 10-99 and described in Table 10-83.

Return to Summary Table.

The interrupt enable clear registers (IECR/IECRH) are used to clear interrupts. Writes of 1 to the bits in IECR/IECRH clear the corresponding interrupt bits in the interrupt enable registers (IER/IERH); writes of 0 have no effect. All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

10.4.1.62 IPR Register (Offset = 1068h) [reset = 0h]

IPR is shown in Figure 10-103 and described in Table 10-87.

Return to Summary Table.

If the TCINTEN and/or ITCINTEN bit in the channel option parameter (OPT) is set in the PaRAM entry associated with the channel (DMA or QDMA), then the EDMA3TC (for normal completion) or the EDMA3CC (for early completion) returns a completion code on transfer or intermediate transfer completion. The value of the returned completion code is equal to the TCC bit in OPT for the PaRAM entry associated with the channel. When an interrupt transfer completion code with TCC = n is detected by the EDMA3CC, then the corresponding bit is set in the interrupt pending register (IPR.In, if n = 0 to 31; IPRH.In, if n = 32 to 63). Note that once a bit is set in the interrupt pending registers, it remains set; it is your responsibility to clear these bits. The bits set in IPR/IPRH are cleared by writing a 1 to the corresponding bits in the interrupt clear registers (ICR/ICRH). All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

10.4.1.64 ICR Register (Offset = 1070h) [reset = 0h]

ICR is shown in Figure 10-105 and described in Table 10-89.

Return to Summary Table.

The bits in the interrupt pending registers (IPR/IPRH) are cleared by writing a 1 to the corresponding bits in the interrupt clear registers(ICR/ICRH). Writes of 0 have no effect. All set bits in IPR/IPRH must be cleared to allow EDMA3CC to assert additional transfer completion interrupts. All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

10.4.1.66 IEVAL Register (Offset = 1078h) [reset = 0h]

IEVAL is shown in Figure 10-107 and described in Table 10-91.

Return to Summary Table.

The interrupt evaluate register (IEVAL) is the only register that physically exists in both the global region and the shadow regions. In other words, the read/write accessibility for the shadow region IEVAL is not affected by the DMA/QDMA region access registers (DRAEm/DRAEHm, QRAEn/QRAEHn). IEVAL is needed for robust ISR operations to ensure that interrupts are not missed by the CPU. All DMA/QDMA channels can be set to assert an EDMA3CC completion interrupt to the CPU on transfer completion, by appropriately configuring the PaRAM entry associated with the channels. This register is used for the transfer completion interrupt reporting/generating by the EDMA3CC. For more details on EDMA3CC completion interrupt generation, see EDMA3 Interrupts.

Bit	Field	Type	Reset	Description
31-2	RESERVED	R	0h	
1	RESERVED	R	0h	
0	EVAL	W	0h	Interrupt evaluate. The EDMA3CC completion interrupt that is pulsed depends on which IEVAL is being exercised. For example, writing to the EVAL bit in IEVAL pulses the global completion interrupt, but writing to the EVAL bit in IEVAL0 pulses the region 0 completion interrupt. 0h (R/W) = No effect. 1h (R/W) = Causes EDMA3CC completion interrupt to be pulsed, if any enabled (IERn/IERHn = 1) interrupts are still pending (IPRn/IPRHn = 1).

10.4.1.67 QER Register (Offset = 1080h) [reset = 0h]

QER is shown in Figure 10-108 and described in Table 10-92.

Return to Summary Table.

The QDMA event register (QER) channel n bit is set (En = 1) when the CPU or any EDMA3 programmer (including EDMA3) performs a write to the trigger word (using the QDMA channel mapping register (QCHMAPn)) in the PaRAM entry associated with QDMA channel n (which is also programmed using QCHMAPn). The En bit is also set when the EDMA3CC performs a link update on a PaRAM address that matches the QCHMAPn settings. The QDMA event is latched only if the QDMA event enable register (QEER) channel n bit is also enabled (QEER.En = 1). Once a bit is set in QER, then the corresponding QDMA event (auto-trigger) is evaluated by the EDMA3CC logic for an associated transfer request submission to the transfer controllers. For additional conditions that can lead to the setting of QER bits, see EDMA Overview. The setting of an event is a higher priority relative to clear operations (via hardware). If set and clear conditions occur concurrently, the set condition wins. If the event was previously set, then the QDMA event missed register (QEMR) would be set because an event is lost. If the event was previously clear, then the event remains set and is prioritized for submission to the event queues. The set bits in QER are only cleared when the transfer request associated with the corresponding channels has been processed by the EDMA3CC and submitted to the transfer controller. If the En bit is already set and a QDMA event for the same QDMA channel occurs prior to the original being cleared, then the second missed event is latched in QEMR (En = 1). QER is part of a set of register that control the QDMA channels in EDMA3CC. QDMA channels (with the exception of the QDMA queue number register) consist of a set of registers, each of which have a bit location. Each bit position corresponds to a QDMA channel number. The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write accessibility in the shadow region address region is controlled by the QDMA region access registers (QRAEn/QRAEHn).

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	En	R	0h	QDMA event for channels 0 to 7. 0h (R/W) = No effect. 1h (R/W) = Corresponding QDMA event is prioritized versus other pending DMA/QDMA events for submission to the EDMA3TC.

10.4.1.68 QEER Register (Offset = 1084h) [reset = 0h]

QEER is shown in Figure 10-109 and described in Table 10-93.

Return to Summary Table.

The EDMA3CC provides the option of selectively enabling/disabling each channel in the QDMA event register (QER) by using the QDMA event enable register (QEER). If any of the event bits in QEER is set (using the QDMA event enable set register, QEESR), it will enable that corresponding event. Alternatively, if any event bit in QEER is cleared (using the QDMA event enable clear register, QEECR), it will disable the corresponding QDMA channel. The QDMA event register will not latch any event for a QDMA channel, if it is not enabled via QEER. QEER is part of a set of register that control the QDMA channels in EDMA3CC. QDMA channels (with the exception of the QDMA queue number register) consist of a set of registers, each of which have a bit location. Each bit position corresponds to a QDMA channel number. The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write accessibility in the shadow region address region is controlled by the QDMA region access registers (QRAEn/QRAEHn).

QDMA event will not be recognized and will not latch in the QDMA event register (QER). 1h (R/W) = QDMA channel n is enabled. QDMA events will be recognized and will get latched in the QDMA event register (QER).

10.4.1.69 QEECR Register (Offset = 1088h) [reset = 0h]

QEECR is shown in Figure 10-110 and described in Table 10-94.

Return to Summary Table.

The QDMA event enable register (QEER) cannot be modified by directly writing to the register, to ease the software burden when multiple tasks are attempting to simultaneously modify these registers. The QDMA event enable clear register (QEECR) is used to disable events. Writes of 1 to the bits in QEECR clear the corresponding QDMA channel bits in QEER; writes of 0 have no effect. QEECR is part of a set of register that control the QDMA channels in EDMA3CC. QDMA channels (with the exception of the QDMA queue number register) consist of a set of registers, each of which have a bit location. Each bit position corresponds to a QDMA channel number. The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write accessibility in the shadow region address region is controlled by the QDMA region access registers (QRAEn/QRAEHn).

Table 10-95. QEESR Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	En	W	0h	QDMA event enable set for channels 0 to 7. 0h (R/W) = No effect. 1h (R/W) = QDMA event is enabled. Corresponding bit in the QDMA event enable register (QEER) is set (En = 1).

10.4.1.71 QSER Register (Offset = 1090h) [reset = 0h]

QSER is shown in Figure 10-112 and described in Table 10-96.

Return to Summary Table.

The QDMA secondary event register (QSER) provides information on the state of a QDMA event. If at any time a bit corresponding to a QDMA channel is set in QSER, that implies that the corresponding QDMA event is in the queue. Once a bit corresponding to a QDMA channel is set in QSER, the EDMA3CC does not prioritize additional events on the same QDMA channel. Depending on the condition that lead to the setting of the QSER bits, either the EDMA3CC hardware or the software (using QSECR) needs to clear the QSER bits for the EDMA3CC to evaluate subsequent QDMA events on the channel. Based on whether the associated TR request is valid, or it is a null or dummy TR, the implications on the state of QSER and the required user actions to submit another QDMA transfer might be different. For additional conditions that can cause the secondary event registers (QSER\SER) to be set, see EDMA Overview. QSER is part of a set of register that control the QDMA channels in EDMA3CC. QDMA channels (with the exception of the QDMA queue number register) consist of a set of registers, each of which have a bit location. Each bit position corresponds to a QDMA channel number. The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write accessibility in the shadow region address region is controlled by the QDMA region access registers (QRAEn/QRAEHn).

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7-0	En	R	0h	QDMA secondary event register for channels 0 to 7. 0h (R/W) = QDMA event is not currently stored in the event queue. 1h (R/W) = QDMA event is currently stored in the event queue. EDMA3CC will not prioritize additional events.

10.4.1.72 QSECR Register (Offset = 1094h) [reset = 0h]

QSECR is shown in Figure 10-113 and described in Table 10-97.

Return to Summary Table.

The QDMA secondary event clear register (QSECR) clears the status of the QDMA secondary event register (QSER) and the QDMA event register (QER). CPU writes of 1 clear the corresponding set bits in QSER and QER. Writes of 0 have no effect. Note that this differs from the secondary event clear register (SECR) operation, which only clears the secondary event register (SER) bits and does not affect the event registers. QESCR is part of a set of register that control the QDMA channels in EDMA3CC. QDMA channels (with the exception of the QDMA queue number register) consist of a set of registers, each of which have a bit location. Each bit position corresponds to a QDMA channel number. The QDMA channel registers are accessible via read/writes to the global address range. They are also accessible via read/writes to the shadow address range. The read/write accessibility in the shadow region address region is controlled by the QDMA region access registers (QRAEn/QRAEHn).

</table>

Table 10-101. SYSCONFIG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-6	RESERVED	R	0h	
5-4	STANDBYMODE	R/W	2h	Configuration of the local initiator state management mode. By definition, initiator may generate read/write transaction as long as it is out of STANDBY state. 0h (R/W) = Force-standby mode: local initiator is unconditionally placed in standby state. Backup mode, for debug only. 1h (R/W) = No-standby mode: local initiator is unconditionally placed out of standby state. Backup mode, for debug only. 2h (R/W) = Smart-standby mode: local initiator standby status depends on local conditions, i.e., the module's functional requirement from the initiator. IP module should not generate (initiator-related) wakeup events. 3h (R/W) = Reserved.
3-2	IDLEMODE	R/W	2h	Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state. 0h (R/W) = Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, i.e. regardless of the IP module's internal requirements. Backup mode, for debug only. 1h (R/W) = No-idle mode: local target never enters idle state. Backup mode, for debug only. 2h (R/W) = Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ or DMA-request-related) wakeup events. 3h (R/W) = Reserved.
1-0	RESERVED	R	0h	

10.4.2.4 TCSTAT Register (offset = 100h) [reset = 100h]

TCSTAT is shown in Figure 10-117 and described in Table 10-102.

Table 10-102. TCSTAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-14	RESERVED	R	0h	
13-12	DFSTRTPTR	R	0h	Destination FIFO start pointer. Represents the offset to the head entry of the destination register FIFO, in units of entries. Value 0 to 3h.
11-9	RESERVED	R	0h	
8	RESERVED	R	1h	
7	RESERVED	R	0h	
6-4	DSTACTV	R	0h	Destination active state. Specifies the number of transfer requests (TRs) that are resident in the destination register FIFO at a given instant. This bit field can be primarily used for advanced debugging. Legal values are constrained by the destination register FIFO depth parameterization (DSTREGDEPTH) parameter. 0h (R/W) = Destination FIFO is empty. 1h (R/W) = Destination FIFO contains 1 TR. 2h (R/W) = Destination FIFO contains 2 TRs. 3h (R/W) = Destination FIFO contains 3 TRs. 4h (R/W) = Destination FIFO contains 4 TRs. (Full if DSTREGDEPTH==4). If the destination register FIFO is empty, then any TR written to Prog Set immediately transitions to the destination register FIFO. If the destination register FIFO is not empty and not full, then any TR written to Prog Set immediately transitions to the destination register FIFO set if the source active state (SRCACTV) bit is set to idle. If the destination register FIFO is full, then TRs cannot transition to the destination register FIFO. The destination register FIFO becomes not full when the TR at the head of the destination register FIFO is completed. 5h (R/W) = Reserved. 6h (R/W) = Reserved. 7h (R/W) = Reserved.
3	RESERVED	R	0h	
2	WSACTV	R	0h	Write status active 0h (R/W) = Write status is not pending. Write status has been received for all previously issued write commands. 1h (R/W) = Write status is pending. Write status has not been received for all previously issued write commands.

Table 10-102. TCSTAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	SRCACTV	R	0h	Source active state 0h (R/W) = Source controller is idle. Source active register set contains a previously processed transfer request. 1h (R/W) = Source controller is busy servicing a transfer request.
0	PROGBUSY	R	0h	Program register set busy 0h (R/W) = Program set idle and is available for programming by the EDMA3CC. 1h (R/W) = Program set busy

10.4.2.5 ERRSTAT Register (offset = 120h) [reset = 0h]

ERRSTAT is shown in Figure 10-118 and described in Table 10-103.

1	RESERVED	R	0h	
0	EVAL	W	0h	Error evaluate 0h (R/W) = No effect 1h (R/W) = EDMA3TC error line is pulsed if any of the error status register (ERRSTAT) bits are set.

10.4.2.10 RDRATE Register (offset = 140h) [reset = 0h]

RDRATE is shown in Figure 10-123 and described in Table 10-108.

The EDMA3 transfer controller issues read commands at a rate controlled by the read rate register (RDRATE). The RDRATE defines the number of idle cycles that the read controller must wait before issuing subsequent commands. This applies both to commands within a transfer request packet (TRP) and for commands that are issued for different transfer requests (TRs). For instance, if RDRATE is set to 4 cycles between reads, there are 3 inactive cycles between reads. RDRATE allows flexibility in transfer controller access requests to an endpoint. For an application, RDRATE can be manipulated to slow down the access rate, so that the endpoint may service requests from other masters during the inactive EDMA3TC cycles. Note: The RDRATE value for a transfer controller is expected to be static, as it is decided based on the application requirement. It is not recommended to change the RDRATE value on the fly.

2-0	RDRATE	R/W	0h	Read rate. Controls the number of cycles between read commands. This is a global setting that applies to all TRs for this EDMA3TC. 0h (R/W) = Reads issued as fast as possible. 1h (R/W) = 4 cycles between reads. 2h (R/W) = 8 cycles between reads. 3h (R/W) = 16 cycles between reads. 4h (R/W) = 32 cycles between reads. 5h (R/W) = Reserved. 6h (R/W) = Reserved. 7h (R/W) = Reserved.

10.4.2.11 SAOPT Register (offset = 240h) [reset = 0h]

SAOPT is shown in Figure 10-124 and described in Table 10-109.

The Source Active Options Register (SAOPT) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Source Active Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing the status of the transfer controller (TC) during a transfer.

15-0	ACNT	R	0h	A dimension count remaining for the Source Active Register Set. Number of bytes to be transferred in first dimension.

10.4.2.14 SADST Register (offset = 24Ch) [reset = 0h]

SADST is shown in Figure 10-127 and described in Table 10-112.

The Source Active Destination Address Register (SADST) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Source Active Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing the status of the transfer controller (TC) during a transfer. Note: Destination address is not applicable for Source Active Register Set. Read returns 0.

Table 10-113. SABIDX Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	DBIDX	R	0h	B-Index offset between destination arrays. Represents the offset in bytes between the starting address of each destination array (there are BCND arrays of ACNT elements). DBIDX is always used regardless of whether DAM is in Increment or FIFO mode.
15-0	SBIDX	R	0h	B-Index offset between source arrays. Represents the offset in bytes between the starting address of each source array (there are BCNT arrays of ACNT elements). SBIDX is always used regardless of whether SAM is in Increment or FIFO mode. Value 0 to FFFFh.

10.4.2.16 SAMPPRXY Register (offset = 254h) [reset = 0h]

SAMPPRXY is shown in Figure 10-129 and described in Table 10-114.

The Source Active Memory Protection Proxy Register (SAMPPRXY) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Source Active Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing the status of the transfer controller (TC) during a transfer.

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	
8	PRIV	R	0h	Privilege level. The privilege level used by the host to set up the parameter entry in the channel controller. This field is set up when the associated TR is submitted to the EDMA3TC. The privilege ID is used while issuing read and write command to the target endpoints so that the target endpoints can perform memory protection checks based on the PRIV of the host that set up the DMA transaction. 0h (R/W) = User-level privilege. 1h (R/W) = Supervisor-level privilege.
7-4	RESERVED	R	0h	
3-0	PRIVID	R	0h	Privilege ID. This contains the privilege ID of the host that set up the parameter entry in the channel controller. This field is set up when the associated TR is submitted to the EDMA3TC. This PRIVID value is used while issuing read and write commands to the target endpoints so that the target endpoints can perform memory protection checks based on the PRIVID of the host that set up the DMA transaction. Value 0 to Fh.

10.4.2.17 SACNTRLD Register (offset = 258h) [reset = 0h]

SACNTRLD is shown in Figure 10-130 and described in Table 10-115.

The Source Active Count Reload Register (SACNTRLD) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Source Active Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing the status of the transfer controller (TC) during a transfer.

1	DAM	R	0h	Destination address mode within an array 0h (R/W) = Increment (INCR) mode. Destination addressing within an array increments. 1h (R/W) = Constant addressing (CONST) mode. Destination addressing within an array wraps around upon reaching FIFO width.
0	SAM	R	0h	Source address mode within an array 0h (R/W) = Increment (INCR) mode. Source addressing within an array increments. 1h (R/W) = Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width.

10.4.2.24 DFSRC0 Register (offset = 304h) [reset = 0h]

DFSRC0 is shown in Figure 10-137 and described in Table 10-122.

The Destination FIFO Source Address Register (DFSRC) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers. Note: Source address is not applicable for Destination FIFO Register Set. Read returns 0.

</table>

Table 10-123. DFCNT0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	BCNT	R	0h	B-dimension count remaining for Destination Register Set. Represents the amount of data remaining to be written. For the final TR in the Destination Register FIFO: TC decrements ACNT and BCNT as necessary after each write dataphase is issued. The final value should be 0 when TR is complete. For a non-final TR in the Destination Register FIFO: CNT will hold the originally programmed value or the optimized BCNT value after 2D optimization calculation.
15-0	ACNT	R	0h	A-dimension count remaining for Destination Register Set. Represents the amount of data remaining to be written. For the final TR in the Destination Register FIFO: TC decrements ACNT and BCNT as necessary after each write dataphase is issued. The final value should be 0 when TR is complete. For a non-final TR in the Destination Register FIFO: CNT will hold the originally programmed value or the optimized BCNT value after 2D optimization calculation. Value 0 to FFFFh.

10.4.2.26 DFDST0 Register (offset = 30Ch) [reset = 0h]

DFDST0 is shown in Figure 10-139 and described in Table 10-124.

The Destination FIFO Destination Address Register (DFDST) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

Table 10-125. DFBIDX0 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	DBIDX	R	0h	B-Index offset between destination arrays for the Destination FIFO Register Set. Represents the offset in bytes between the starting address of each destination array (there are BCNT arrays of ACNT elements). DBIDX is always used regardless of whether DAM is in Increment or FIFO mode. Value 0 to FFFFh.
15-0	SBIDX	R	0h	B-Index offset between source arrays for the Destination FIFO Register Set. Represents the offset in bytes between the starting address of each source array (there are BCNT arrays of ACNT elements). SBIDX is always used regardless of whether SAM is in Increment or FIFO mode.

10.4.2.28 DFMPPRXY0 Register (offset = 314h) [reset = 0h]

DFMPPRXY0 is shown in Figure 10-141 and described in Table 10-126.

The Destination FIFO Memory Protection Proxy Register (DFMPPRXY) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

1	DAM	R	0h	Destination address mode within an array 0h (R/W) = Increment (INCR) mode. Destination addressing within an array increments. 1h (R/W) = Constant addressing (CONST) mode. Destination addressing within an array wraps around upon reaching FIFO width.
0	SAM	R	0h	Source address mode within an array 0h (R/W) = Increment (INCR) mode. Source addressing within an array increments. 1h (R/W) = Constant addressing (CONST) mode. Source addressing within an array wraps around upon reaching FIFO width.

10.4.2.36 DFSRC2 Register (offset = 384h) [reset = 0h]

DFSRC2 is shown in Figure 10-149 and described in Table 10-134.

The Destination FIFO Source Address Register (DFSRC) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers. Note: Source address is not applicable for Destination FIFO Register Set. Read returns 0.

10.4.2.37 DFCNT2 Register (offset = 388h) [reset = 0h]

DFCNT2 is shown in Figure 10-150 and described in Table 10-135.

The Destination FIFO Count Register (DFCNT) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

Table 10-135. DFCNT2 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	BCNT	R	0h	B-dimension count remaining for Destination Register Set. Represents the amount of data remaining to be written. For the final TR in the Destination Register FIFO: TC decrements ACNT and BCNT as necessary after each write dataphase is issued. The final value should be 0 when TR is complete. For a non-final TR in the Destination Register FIFO: CNT will hold the originally programmed value or the optimized BCNT value after 2D optimization calculation.
15-0	ACNT	R	0h	A-dimension count remaining for Destination Register Set. Represents the amount of data remaining to be written. For the final TR in the Destination Register FIFO: TC decrements ACNT and BCNT as necessary after each write dataphase is issued. The final value should be 0 when TR is complete. For a non-final TR in the Destination Register FIFO: CNT will hold the originally programmed value or the optimized BCNT value after 2D optimization calculation. Value 0 to FFFFh.

10.4.2.38 DFDST2 Register (offset = 38Ch) [reset = 0h]

DFDST2 is shown in Figure 10-151 and described in Table 10-136.

The Destination FIFO Destination Address Register (DFDST) is an EDMA3TC channel register. This EDMA3TC channel register is part of the Destination Register FIFO Register Set. It is read-only and provided to facilitate debugging by providing a window into how the transfer controller (TC) was programmed by the channel controller (CC), as well as showing status of the transfer controller (TC) during a transfer. The number of destination FIFO register sets depends on the destination FIFO depth. TC0, TC1, and TC2 each have a destination FIFO depth of 4, so there are four sets of destination FIFO registers for each of these transfer controllers.

10.5 Appendix A

10.5.1 Debug Checklist

This section lists some tips to keep in mind while debugging applications using the EDMA3.

The following table provides some common issues and their probable causes and resolutions.

Table 10-145. Debug List

Issue	Description/Solution
The transfer associated with the channel does not happen. The channel does not get serviced.	The EDMA3CC may not service a transfer request, even though the associated PaRAM set is programmed appropriately. Check for the following: 1) Verify that events are enabled, i.e., if an external/peripheral event is latched in Event Registers (ER/ERH), make sure that the event is enabled in the Event Enable Registers (EER/EERH). Similarly, for QDMA channels, make sure that QDMA events are appropriately enabled in the QDMA Event Enable Register (QEER). 2) Verify that the DMA or QDMA Secondary Event Register (SER/SERH/QSERH) bits corresponding to the particular event or channel are not set.
The Secondary Event Registers bits are set, not allowing additional transfers to occur on a channel.	It is possible that a trigger event was received when the parameter set associated with the channel/event was a NULL set for a previous transfer on the channel. This is typical in two cases: 1) QDMA channels: Typically if the parameter set is non-static and expected to be terminated by a NULL set (i.e., OPT.STATIC = 0, LINK = 0xFFFF), the parameter set is updated with a NULL set after submission of the last TR. Because QDMA channels are auto-triggered, this update caused the generation of an event. An event generated for a NULL set causes an error condition and results in setting the bits corresponding to the QDMA channel in the QEMR and QSER. This will disable further prioritization of the channel. 2) DMA channels used in a continuous mode: The peripheral may be set up to continuously generate infinite events (for instance, in case of McASP, every time the data shifts out from the DXR register, it generates an XEVT). The parameter set may be programmed to expect only a finite number of events and to be terminated by a NULL link. After the expected number of events, the parameter set is reloaded with a NULL parameter set. Because the peripheral will generate additional events, an error condition is set in the SER.Ex and EMR.Ex set, preventing further event prioritization. You must ensure that the number of events received is limited to the expected number of events for which the parameter set is programmed, or you must ensure that bits corresponding to particular channel or event are not set in the Secondary event registers (SER/SERH/QSER) and Event Missed Registers (EMR/EMRH/QEMR) before trying to perform subsequent transfers for the event/channel.
Completion interrupts are not asserted, or no further interrupts are received after the first completion interrupt.	You must ensure the following: 1) The interrupt generation is enabled in the OPT of the associated PaRAM set (TCINTEN = 1 and/or ITCINTEN = 1). 2) The interrupts are enabled in the EDMA3 Channel Controller, via the Interrupt Enable Registers (IER/IERH). 3) The corresponding interrupts are enabled in the device interrupt controller. 4) The set interrupts are cleared in the interrupt pending registers (IPR/IPRH) before exiting the transfer completion interrupt service routine (ISR). See Section 10.3.9.1.2 for details on writing EDMA3 ISRs. 5) If working with shadow region interrupts, make sure that the DMA Region Access registers (DRAE/DRAEH) are set up properly, because the DRAE/DRAEH registers act as secondary enables for shadow region completion interrupts, along with the IER/IERH registers. If working with shadow region interrupts, make sure that the bits corresponding to the transfer completion code (TCC) value are also enabled in the DRAE/DRAEH registers. For instance, if the PaRAM set associated with Channel 0 returns a completion code of 63 (OPT.TCC=63), ensure that DRAEH.E63 is also set for a shadow region completion interrupt because the interrupt pending register bit set will be IPRH.I63 (not IPR.I0).

10.5.2 Miscellaneous Programming/Debug Tips

1. For several registers, the setting and clearing of bits needs to be done via separate dedicated registers. For example, the Event Register (ER/ERH) can only be cleared by writing a 1 to the corresponding bits in the Event Clear Registers (ECR/ECRH). Similarly, the Event Enable Register (EER/EERH) bits can only be set with writes of 1 to the Event Enable Set Registers (EESR/EESRH) and cleared with writes of 1 to the corresponding bits in the Event Enable Clear Register (EECR/EECRH).
2. Writes to the shadow region memory maps are governed by region access registers (DRAE/DRAEH/QRAE). If the appropriate channels are not enabled in these registers, read/write access to the shadow region memory map is not enabled.
3. When working with shadow region completion interrupts, ensure that the DMA Region Access Registers (DRAE/DRAEH) for every region are set in a mutually exclusive way (unless it is a requirement for an application). If there is an overlap in the allocated channels and transfer completion codes (setting of Interrupt Pending Register bits) in the region resource allocation, it results in multiple

shadow region completion interrupts. For example, if DRAE0.E0 and DRAE1.E0 are both set, then on completion of a transfer that returns a TCC=0, they will generate both shadow region 0 and 1 completion interrupts.

4. While programming a non-dummy parameter set, ensure the CCNT is not left to zero.
5. Enable the EDMA3CC error interrupt in the device controller and attach an interrupt service routine (ISR) to ensure that error conditions are not missed in an application and are appropriately addressed with the ISR.
6. Depending on the application, you may want to break large transfers into smaller transfers and use self-chaining to prevent starvation of other events in an event queue.
7. In applications where a large transfer is broken into sets of small transfers using chaining or other methods, you might choose to use the early chaining option to reduce the time between the sets of transfers and increase the throughput. However, keep in mind that with early completion, all data might have not been received at the end point when completion is reported because the EDMA3CC internally signals completion when the TR is submitted to the EDMA3TC, potentially before any data has been transferred.
8. The event queue entries can be observed to determine the last few events if there is a system failure (provided the entries were not bypassed).

10.5.3 Setting Up a Transfer

The following list provides a quick guide for the typical steps involved in setting up a transfer.

Step 1. Initiating a DMA/QDMA channel

1. Determine the type of channel (QDMA or DMA) to be used.
2. Channel mapping
    - i. If using a QDMA channel, program the QCHMAP with the parameter set number to which the channel maps and the trigger word.
    - ii. If using a DMA channel, program the DCHMAP with the parameter set number to which the channel maps.
3. If the channel is being used in the context of a shadow region, ensure the DRAE/DRAEH for the region is properly set up to allow read write accesses to bits in the event registers and interrupt registers in the Shadow region memory map. The subsequent steps in this process should be done using the respective shadow region registers. (Shadow region descriptions and usage are provided in Section 10.3.7.1.)
4. Determine the type of triggering used.
    - i. If external events are used for triggering (DMA channels), enable the respective event in EER/EERH by writing into EESR/EESRH.
    - ii. If QDMA Channel is used, enable the channel in QEER by writing into QEESR.
5. Queue setup
    - i. If a QDMA channel is used, set up the QDMAQNUM to map the channel to the respective event queue.
    - ii. If a DMA channel is used, set up the DMAQNUM to map the event to the respective event queue.

Step 2. Parameter set setup

1. Program the PaRAM set number associated with the channel. Note that if it is a QDMA channel, the PaRAM entry that is configured as trigger word is written to last. Alternatively, enable the QDMA channel (step 1-b-ii above) just before the write to the trigger word.
   See Section 10.3.19 for parameter set field setups for different types of transfers. See the sections on chaining (Section 10.3.8) and interrupt completion (Section 10.3.9) on how to set up final/intermediate completion chaining and/or interrupts.

Step 3. Interrupt setup

1. Enable the interrupt in the IER/IERH by writing into IESR/IESRH.
2. Ensure that the EDMA3CC completion interrupt (either the global or the shadow region interrupt) is enabled properly in the device interrupt controller.
3. Ensure the EDMA3CC completion interrupt (this refers to either the Global interrupt or the shadow region interrupt) is enabled properly in the Device Interrupt controller.
4. Set up the interrupt controller properly to receive the expected EDMA3 interrupt.

Step 4. Initiate transfer

1. This step is highly dependent on the event trigger source:
    - i. If the source is an external event coming from a peripheral, the peripheral will be enabled to start generating relevant EDMA3 events that can be latched to the ER transfer.
    - ii. For QDMA events, writes to the trigger word (step 2-a above) will initiate the transfer.
    - iii. Manually triggered transfers will be initiated by writes to the Event Set Registers (ESR/ESRH).
    - iv. Chained-trigger events initiate when a previous transfer returns a transfer completion code equal to the chained channel number.

Step 5. Wait for completion

1. If the interrupts are enabled as mentioned in step 3 above, then the EDMA3CC will generate a completion interrupt to the CPU whenever transfer completion results in setting the corresponding bits in the interrupt pending register (IPR/IPRH). The set bits must be cleared in the IPR\IPRH by writing to corresponding bit in ICR\ICRH.
2. If polling for completion (interrupts not enabled in the device controller), then the application code can wait on the expected bits to be set in the IPR\IPRH. Again, the set bits in the IPR\IPRH must be manually cleared via ICR\ICRH before the next set of transfers is performed for the same transfer completion code values.

ADC0: Touchscreen Controller

This chapter describes the touchscreen controller of the device.

NOTE: The Touchscreen Controller (TSC) is not supported for the AMIC120.

Topic **Page**

11.1 Introduction

The touchscreen controller and analog-to-digital converter subsystem (TSC_ADC_SS or ADC0) contains a single-channel ADC connected to an 8-to-1 analog multiplexer which operates as a general-purpose analog-to-digital converter (ADC) with optional support for interleaving touchscreen (TS) conversions for a 4-wire, 5-wire, or 8-wire resistive panel. The TSC_ADC_SS can be configured for use in one of the following applications:

- 8 general-purpose ADC channels
- 4-wire TSC with 4 general-purpose ADC channels
- 5-wire TSC with 3 general-purpose ADC channels
- 8-wire TSC

11.1.1 TSC_ADC (ADC0) Features

The main features of the TSC_ADC_SS include:

- Support for 4-wire, 5-wire, and 8-wire resistive TS panels
- Support for interleaving TS capture and general-purpose ADC modes
- Programmable FSM sequencer that supports 16 steps:
  - Software register bit for start of conversion
  - Optional start of conversion HW synchronized to Pen touch or external HW event (but not both)
  - Single conversion (one-shot)
  - Continuous conversions
  - Sequence through all input channels based on a mask
  - Programmable OpenDelay for each FSM step
  - Programmable sampling delay for each FSM step
  - Programmable averaging of input samples: 16/8/4/2/1
  - Differential or singled ended mode setting for each FSM step
  - Store data in either of two FIFO groups
  - Option to encode step ID number with data
  - Support for servicing FIFOs via DMA or CPU
  - Programmable DMA Request event (for each FIFO)
  - Dynamically enable or disable channel inputs during operation
  - Stop bit to end conversion
- Support for the following interrupts and status, with masking:
  - Interrupt for HW pen event (Pen-down)
  - Interrupt for HW Pen-up event
  - Interrupt after a sequence of conversions (all non-masked channels)
  - Interrupt for FIFO threshold levels
  - Interrupt if sampled data is out of a programmable range
  - Interrupt for FIFO overflow and underflow conditions
  - Status bit to indicate if ADC is busy converting

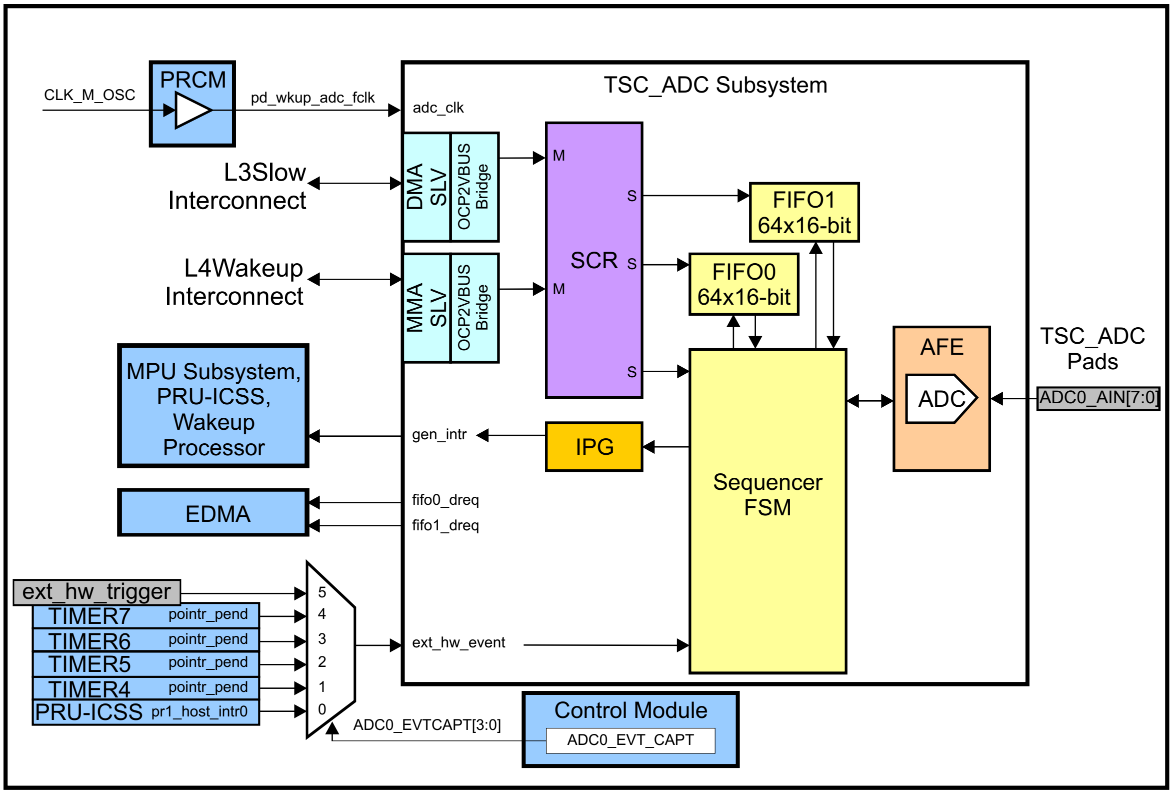
11.1.2 Unsupported TSC_ADC_SS (ADC0) Features

This device supports all TSC_ADC_SS features.

11.2 Integration

Figure 11-1 shows the integration of the TSC_ADC (ADC0) module in the device.

Figure 11-1. TSC_ADC (ADC0) Integration



pr1_host_intr[0:7] corresponds to Host-2 to Host-9 of the PRU-ICSS interrupt controller.

11.2.1 TSC_ADC (ADC0) Connectivity Attributes

The general connectivity attributes for the TSC_ADC module are summarized in Table 11-1.

Table 11-1. TSC_ADC (ADC0) Connectivity Attributes

Attributes	Type
Power domain	Wakeup Domain
Clock domain	PD_PER_L3S_GCLK (OCP) PD_WKUP_ADC_FCLK (Func)
Reset signals	WKUP_DOM_RST_N
Idle/Wakeup signals	Smart idle Wakeup
Interrupt request	1 interrupt to MPU Subsystem (ADC0_GENINT), PRU-ICSS (gen_intr_pend), and Wakeup Processor Swakeup to Wake Processor
DMA request	2 Events (adc0_FIFO0, adc0_FIFO1)
Physical address	L3 Slow slave port (DMA) L4 Wkup slave port (MMR)

11.2.2 TSC_ADC (ADC0) Clock and Reset Management

The TSC_ADC has two clock domains. The ADC uses the adc_clk. The bus interfaces, FIFOs, sequencer, and all other lofic use the ocp_clk.

Table 11-2. TSC_ADC (ADC0) Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
ocp_clk OCP / Functional clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_ls3_gclk From PRCM
adc_clk ADC clock	24 MHz (typ)	CLK_M_OSC	pd_wkup_adc_fclk From PRCM

11.2.3 TSC_ADC (ADC0) Pin List

The TSC_ADC external interface signals are shown in Table 11-3.

Table 11-3. TSC_ADC (ADC0) Pin List

Pin	Type	Description
ADC0_AIN[7:0]	I	Analog Input
VREFN	Analog	Analog Reference Input Negative Terminal
VREFP	Analog	Analog Reference Input Positive Terminal

11.3 Functional Description

Before enabling the TSC_ADC_SS module, the user must first program the Step Configuration registers in order to configure a channel input to be sampled. There are 16 programmable Step Configuration registers which are used by the sequencer to control which switches to turn on or off (inputs to the AFE), which channel to sample, and which mode to use (hardware-triggered or software-enabled, one-shot or continuous, averaging, where to save the FIFO data, and more).

11.3.1 Hardware Synchronized or Software Enabled

The user can control the start behavior of each step by deciding if a channel should be sampled immediately (software-enabled) after it is enabled, or if the channel should wait for a hardware (HW) event to occur first (a HW event must either be mapped to the touch screen PEN event or mapped to the HW event input signal, but not both). Each step can be configured independently using the STEPCONFIG_x register.

11.3.2 Open Delay and Sample Delay

The user can program the delay between driving the inputs to the AFE and the time to send the start of conversion signal. This delay can be used to allow the voltages to stabilize on the touch screen panel before sampling. This delay is called “open delay” and can also be programmed to zero. The user also has control of the sampling time (width of the start of conversion signal) to the AFE which is called the “sample delay”. The open delay and sample delay for each step can be independently configured using the STEPDELAY_x register.

11.3.3 Averaging of Samples (1, 2, 4, 8, and 16)

Each step has the capability to average the sampled data. The valid averaging options are 1 (no average), 2, 4, 8, and 16. If averaging is turned on, then the channel is immediately sampled again (up to 16 times) and final averaged sample data is stored in the FIFO. Each step can be independently configured using the STEPCONFIG_x registers.

11.3.4 One-Shot (Single) or Continuous Mode

When the sequencer finishes cycling through all the enabled steps, the user can decide if the sequencer should stop (one-shot), or loop back and schedule the step again (continuous).

If one-shot mode is selected, the sequencer will take care of disabling the step enable bit after the conversion. If continuous mode is selected, it is the software’s responsibility to turn off the step enable bit.

11.3.5 Interrupts

The following interrupts are supported through enable bits and are maskable.

The HW Pen event interrupt, also known as the Pen-down interrupt, is generated when the user presses the touchscreen. This can only occur if the AFE is configured properly (that is, one of the Pen Ctrl bits must be enabled, and also the correct setting for a path to ground in the STEPCONFIG_x registers). Although the Pen-down interrupt can be disabled by the software (SW), the event will still trigger the sequencer to start if the step is configured as a HW-synchronized event. The Pen-down interrupt is an asynchronous event and can be used even if the TSC_ADC_SS clocks are disabled. The Pen-down interrupt can be used as a wakeup source.

An END_OF_SEQUENCE interrupt is generated after the sequencer finishes servicing the last enabled step.

A Pen-up event interrupt, also known as the Pen-up interrupt, can only be generated when using HW steps with the charge steps enabled. If a Pen-down event caused the HW steps to be scheduled and no Pen-down is present after the sequencer finished servicing the charge step, then a Pen-up interrupt is generated. To detect Pen-up interrupts, the charge step must share the same configuration as the idle step.

Each FIFO has support for generating interrupts when the FIFO word count has reached a programmable threshold level. The user can program the desired word count at which the CPU should be interrupted. Whenever the threshold counter value is reached, it sets the FIFOTHR_x interrupt flag, and the CPU is interrupted if the FIFOTHR_x interrupt enable bit is set. The user can clear the interrupt flag, after emptying the FIFO, by writing a ‘1’ to the FIFOTHR_x interrupt status bit. To determine how many samples are currently in the FIFO at a given moment, the FIFOCOUNT_x register can be read by the CPU.

The FIFO can also generate FIFOx_OVERRUN and FIFOx_UNDERFLOW interrupts. The user can mask these events by programming the IRQEN_CLR register. To clear a FIFO underflow or FIFO overrun interrupt, the user should write a ‘1’ to the status bit in the IRQSTS register. The TSC_ADC_SS does not recover from these conditions automatically. Therefore, the software will need to disable and then again enable the TSC_ADC_SS. Before the user can turn the module back on, the user must read the ADCSTAT register to check if the status of the ADC FSM is idle and the current step is the idle step.

11.3.6 DMA Requests

Each FIFO group can be serviced by either a DMA or by the CPU. To generate DMA requests, the user must set the enable bit in the DMAEN_SET Register. Also, the user can program the desired number of words to generate a DMA request using the DMAxREQ register. When the FIFO level reaches or exceeds that value, a DMA request is generated.

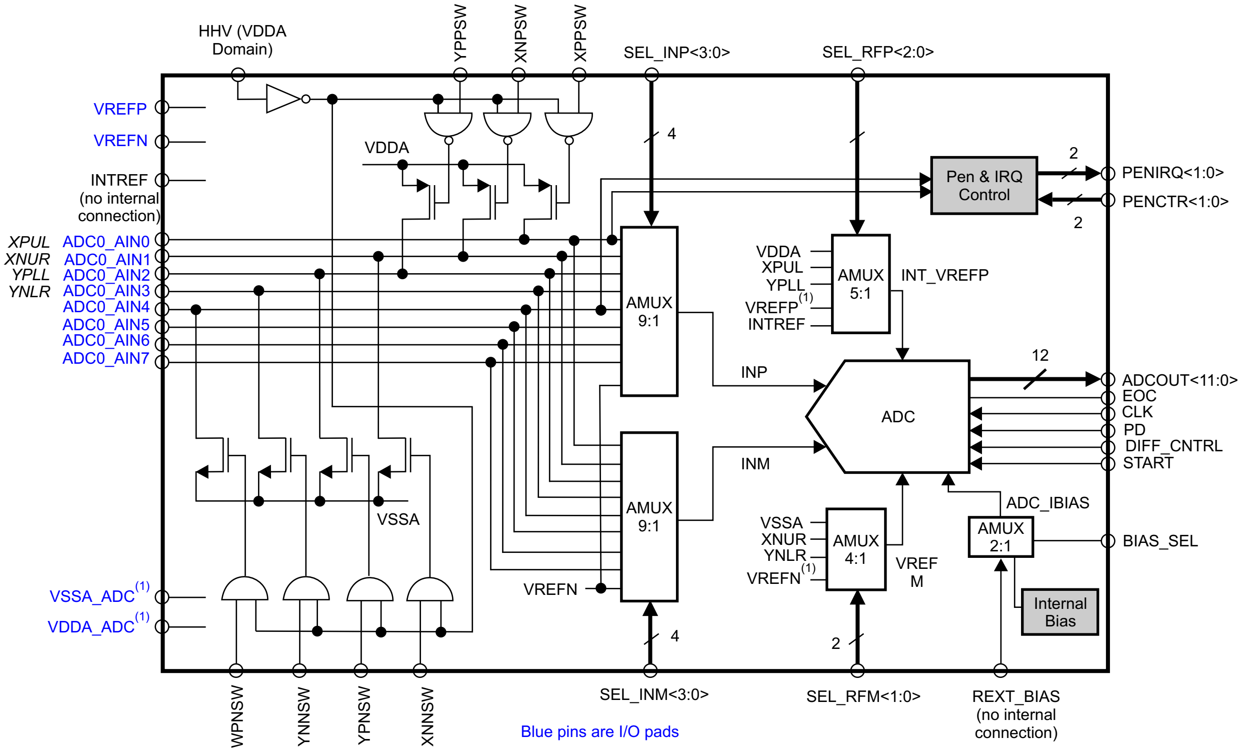
The DMA slave port allows for burst reads in order to effectively move the FIFO data. Internally, the OCP DMA address (MSB) is decoded for either FIFO 0 or FIFO 1. The lower bits of the DMA addresses are ignored since the FIFO pointers are incremented internally.

11.3.7 Analog Front End (AFE) Functional Block Diagram

The AFE features are listed below, and some are controlled by the TSC_ADC_SS:

- 12-bit ADC
- Sampling rate can be as fast as every 15 ADC clock cycles
- Support for internal ADC clock divider logic
- Support for configuring the delay between samples also the sampling time

Figure 11-2. Functional Block Diagram



(1) In the device-specific datasheet:

- VDDA_ADC and VSSA_ADC are referred to as "Internal References"
- VREFP and VREFN are referred to as "External References"

11.4 Operational Modes

The sequencer is completely controlled by software and behaves accordingly to how the **Step Registers** are programmed. A **step** is the general term for sampling a channel input. It is defined by the programmer who decides which input values to send to the AFE as well as how and when to sample a channel input.

The choices for each step can all be programmed using the STEPCONFIG_x registers.

A step requires using these registers:

- STEPEN: Enables or disables the step
- STEPCONFIG_x: Controls the input values to the ADC (the reference voltages, the pull up/down transistor biasing, which input channel to sample, differential control, HW synchronized or SW enabled, averaging, and which FIFO group to save the data)
- STEPDELAY_x: Controls the OpenDelay (the time between driving the AFE inputs until sending the SOC signal to the AFE), and also controls the SampleDelay (the time for the ADC to sample the input signal)

The sequencer supports a total of 16 programmable steps, a touchscreen charge step, and an idle step. Each step requires using the registers listed above. However, the idle step does not have an enable bit, so it will always be enabled, or a delay register. In addition, the ADC does not actually sample a channel during the idle and touchscreen charge steps.

Assuming all the steps are configured as general-purpose mode (no touchscreen), then the steps would be configured as SW enabled. When the TSC_ADC_SS is first enabled, the sequencer will always start in the Idle step and then wait for a STEPEN[n] bit to turn on. After a step is enabled, the sequencer will start with the lowest step (1) and continue until step (16). If a step is not enabled, then sequencer will skip to the next step. If all steps are disabled, then the sequencer will remain in the IDLE state and continue to apply the settings in the IDLECONFIG register.

Assuming a touchscreen-only mode (no general-purpose channels) the steps could be configured as HW synchronized triggered (mapped to the Pen event). The sequencer would wait in the IDLE state until a Pen-down event occurred and then begin the HW step conversions. The charge step, which occurs after the last HW-synchronized step is finished, is designed to charge the capacitance in a touch panel when the appropriate bias transistor is enabled. The purpose of the charge step is to prepare the TSC for the next Pen-down event.

Assuming a mixed mode application (touchscreen and general-purpose channels), the user can configure the steps as either HW-triggered (mapped to a Pen event) or SW-enabled. If the sequencer is in the idle state and a Pen-down event occurs, the HW-synchronized steps are always scheduled first, followed by the charge step, and cannot be preempted by SW steps. If there is no HW event, then the SW-enabled steps are scheduled instead.

If a Pen-down event occurs while the sequencer is in the middle of scheduling the SW steps, the user can program the scheduler to allow preemption. If the HW preemption control bit is enabled in the CTRL register, the sequencer will stop the scheduled SW sequence and schedule the HW steps. After the last HW step and charge step are completed, the sequencer will continue from the next SW step (before the preemption occurred). If the HW preemption is disabled, then the touch event will be ignored until the last software step is completed; if the touch event is removed before the last software step is finished, then the touch event will be missed.

Even if a touchscreen is not present, the user can still configure the steps to be HW-synchronized by mapping to the ext_hw_event signal shown in Figure 11-1. This HW event input signal can be driven at the SOC from a number of external inputs chosen by the ADC0_EVT_CAPT register in the Control Module.

When mapping is set for the ext_hw_event signal, then the TSC_ADC_SS will wait for a rising edge transition (from low to high) before starting. The ext_hw_event signal is captured on the internal L4 OCP clock domain. The ext_hw_event signal should be held for at least two TSC_ADC_SS OCP clocks (L4 frequency).

An END_OF_SEQUENCE interrupt is generated after the last active step is completed before going back to the IDLE state. The END_OF_SEQUENCE interrupt does not mean data is in the FIFO (should use the FIFO interrupts and FIFOCOUNT_x register).

11.4.1 PenCtrl and PenIRQ

The Pen IRQ can only occur if the correct AFE_Pen_Ctrl bits are high in the CTRL register and if the correct ground transistor biasing is set in the STEPCONFIG_x and IDLECONFIG registers.

Setting the AFE_Pen_Ctrl bits in the CTRL register will enable a weak internal pull-up resistor on ADC0_AIN for 4-wire configurations and ADC0_AIN for 5-wire.

If a step is configured as HW-synchronized, the sequencer will override the AFE_Pen_Ctrl bits set by the software (bits 6:5) once it transitions from the Idle step. The sequencer will automatically mask the AFE_Pen_Ctrl bits (override them and turn them off) so that the ADC can get an accurate measurement from the x and y-axes. After the last HW-synchronized step, the sequence will go to the Charge step and the pen override mask is removed and the values set by the software (bits 6:5) will have control. The Pen-down events will be temporarily ignored during the Charge step (HW will mask any potential glitches that may occur)

If the sequencer is not using the HW synchronized approach, (all the steps are configured as software enabled), then it is the software programmer’s responsibility to correctly turn on and off the AFE_Pen_Ctrl bits to receive the correct measurements from the touchscreen. The software must enable the Charge step and ignore any potential glitches.

It is also possible to detect the Pen-down event even if all the STEPEN[n] bits are off. By setting the appropriate AFE_Pen_Ctrl bit to 1, and configuring the IDLECONFIG register to bias the correct transistor to ground, the Pen-down event will generate. The flowchart for the sequencer is shown in Figure 11-3 and an example timing diagram in Figure 11-4.

Figure 11-3. Sequencer FSM

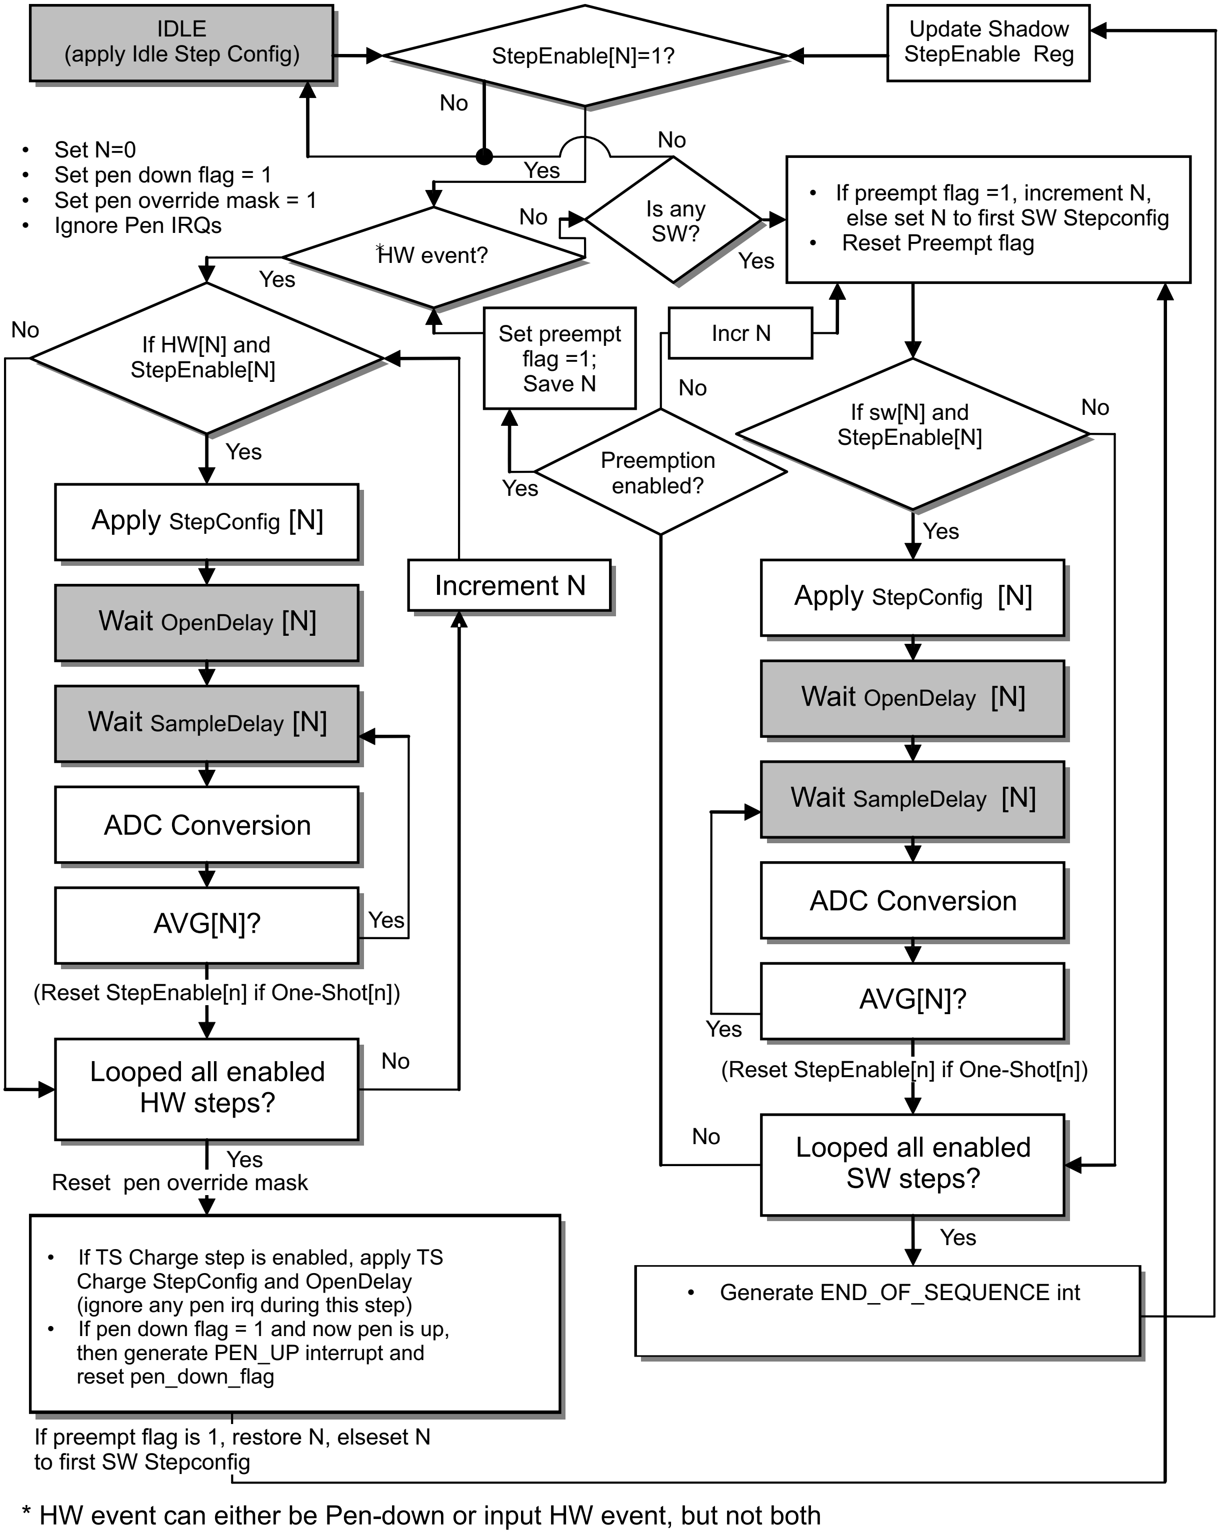


Figure 11-3 does not actually represent clock cycles but instead illustrates how the scheduler will work. However, each shaded box above does represent a FSM state and will use a clock cycle. Using the minimum delay values, the ADC can sample at 15 ADC clocks per sample. Below is an example timing diagram illustrating the states of the sequencer and also the showing when the STEPCONFIG_x and the STEPDELAY_x registers values are applied. The below example assumes the steps are software controlled, and averaging is turned off.

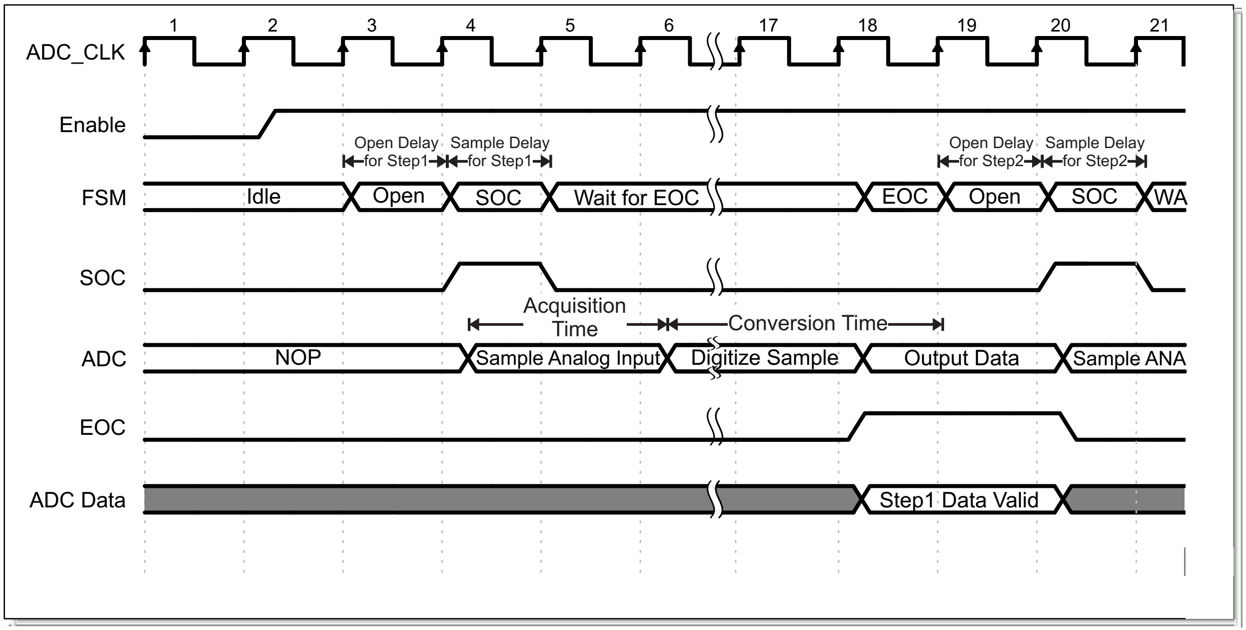
Figure 11-4. Example Timing Diagram for Sequencer



The idle step is always enabled and applied when the FSM is in the IDLE state (that is, either waiting for a HW event or waiting for a step to be enabled). The idle step cannot be disabled.

Once the TSC_ADC_SS is enabled and assuming at least one step is active, the FSM will transition from the idle state and apply the first active STEPCONFIG_x and STEPDELAY_x register settings. It is possible for the Open Delay to be 0, and, as a result, the FSM will immediately skip to the Sample Delay. The ADC will begin sampling once the SoC signal goes high. The ADC will continue to sample for at least 1 clock cycle, which is the Sample Delay minimum, after the SoC. The ADC will then take 12 cycles to digitize the sample followed by 1 cycle to send the EOC for a minimum total of 15 ADC_CLK cycles per sample. Once the EOC has been sent, the FSM will begin the next active step.

This process is repeated and continued (from step 1 to step 16) until the last active step is completed.

11.5 ADC0 Registers

11.5.1 ADC0 Registers

Table 11-4 lists the memory-mapped registers for the ADC0. All register offset addresses not listed in Table 11-4 should be considered as reserved locations and the register contents should not be modified.

Table 11-29. ADC0_FIFO1DATA Register Field Descriptions

Bit	Field	Type	Reset	Description
31-20	RESERVED	R	0h	RESERVED
19-16	ADCCHNLID	R	0h	Optional ID tag of channel that captured the data. If tag option is disabled, these bits will be 0.
15-12	RESERVED	R	0h	RESERVED
11-0	ADCDATA	R	0h	12 bit sampled ADC converted data value stored in FIFO 1.

ADC1: Magnetic Card Reader

This chapter describes the Magnetic Card Reader (ADC1) of the device.

Topic **Page**

12.1 Introduction

The magnetic card reader (MCR) and analog-to-digital converter (ADC) subsystem (MCR_ADC_SS), also known as ADC1, implements several enhancements to the basic general-purpose ADC which allows it to be connected directly to magnetic card heads and operated as a magnet card reader.

ADC1 contains two major components: a digital finite-state machine sequencer (FSM sequencer) and analog front-end (AFE).

The FSM sequencer is set up and controlled by software using a 32-bit OCP interface and supports up to 16 programmable logical steps (a step defines how and when to sample a physical input). The ADC conversion data is stored in either of two FIFOs and can be read by the processor or DMA. Interrupts can be generated when the FIFO data has reached a programmable level. The FSM sequencer supports continuous sampling as well as single-shot modes.

The AFE consists of a single 12-bit successive approximation ADC, 4 programmable gain differential preamplifiers, 4 analog multiplexers, and 8 analog inputs. Analog multiplexers allow the 8 analog inputs to be configured as 4 differential inputs or 8 single-ended inputs when the preamplifiers are bypassed.

NOTE: The magnetic card reader function is not supported on the AM437x product family. ADC1 should only be used as a general-purpose ADC when using an AM437x device.

12.1.1 MagneticCard Reader Features

The main features of the MagneticCard Reader include:

- Programmable FSM sequencer that supports 16 steps:
  - Software register bit for start of sequence
  - Optional start of sequence with hardware events
    - External hardware event connected to the EXT_HW_TRIGGER input
    - ADC data value exceeds a programmable swipe threshold
  - Option to discard ADC data until it exceeds a programmable swipe threshold
    - Supported in software and hardware event modes
  - Continuous or one-shot single sequence
  - Sequence through up to 16 individually enabled steps
  - Programmable analog input selector for each step
  - Programmable Open Delay between steps
  - Programmable Sampling Delay (acquisition period) for each step
  - Programmable averaging of input samples - 16/8/4/2/1
  - Differential or singled ended mode setting for each step
  - Store data in either of two FIFOs
  - Option to encode physical step number with ADC data
  - FIFOs serviced by the processor or DMA
  - Programmable DMA level interrupt (for each FIFO)
  - Programmable FIFO level interrupt (for each FIFO)
  - Stop bit to end conversion
- Support for following interrupts/status, with masking:
  - Interrupt when ADC data is greater than or equal to a programmable swipe threshold
  - Interrupt after a sequence of enabled steps has completed (end_of_sequence)
  - Interrupt when FIFO fills to a programmable threshold
  - Interrupt if sampled data is out of a programmable range
  - Interrupt for FIFO overflow and underflow conditions
  - Status bit to indicate if ADC is busy converting

  - Status bits to indicate which step is currently being executed

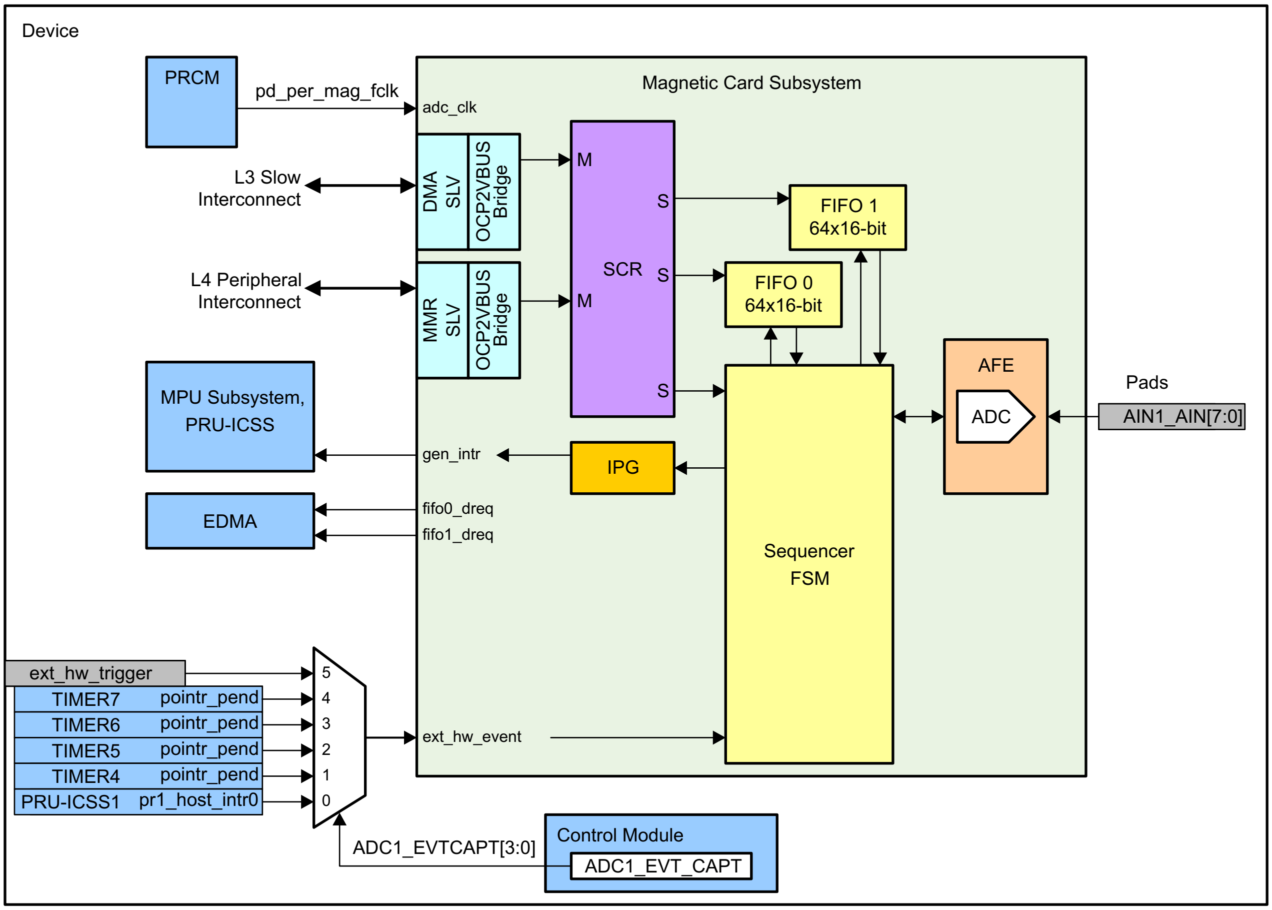
12.1.2 Unsupported Features

The magnetic card reader function is not supported on the AM437x product family. ADC1 should only be used as a general-purpose ADC when using an AM437x device.

12.2 Integration

Figure 12-1 shows how the MCR_ADC (ADC1) module is integrated into the device.

Figure 12-1. MagneticCard Reader Integration



12.2.1 MagneticCard Reader Connectivity Attributes

The general connectivity attributes for the MagneticCard Reader are shown in Table 12-1.

Table 12-1. MagneticCard Reader Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3S_GCLK (OCP) PD_PER_MAG_FCLK (Functional)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Idle
Interrupt Requests	1 interrupt to MPU Subsystem, PRU-ICSS
DMA Requests	1 event Edge event signals to EDMA
Physical Address	L3 slow slave port (DMA) L4 peripheral slave port (MMR)

12.2.2 MagneticCard Reader Clock and Reset Management

The MagneticCard Reader has two clock domains. The OCP2VBUS bridges, SCR, IPG, FIFOs, and portions of the FSM Sequencer use the ocp_clk. The ADC AFE and portions of the FSM Sequencer use the adc_clk.

Table 12-2. MagneticCard Reader Clock Signals

Clock Signal	Maximum Frequency	Reference Source	Comments
ocp_clock Interface / functional clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l3s_gclk from PRCM
adc_clk ADC clock	19.2, 24, 25, or 26 MHz	CLK_M_OSC	pd_per_mgc_fgclk from PRCM
	192 MHz	PER_CLKOUTM2	

The frequency of ocp_clock must be greater than or equal to six times the frequency of adc_clk.

12.2.3 MagneticCard Reader Pin List

The MagneticCard Reader interface pins are summarized in Table 12-3.

Table 12-3. MagneticCard Reader Pin List

Pin	Type	Description
ADC1_AIN[7:0](1)	I	Analog inputs
ADC1_VREFN(2)	Analog	Negative External Reference Voltage Input
ADC1_VREFP(3)	Analog	Positive External Reference Voltage Input

(1) Unused analog inputs should be open-circuit.
(2) Connect ADC1_VREFN to VSSA_ADC when not using a negative external reference voltage.
(3) Connect ADC1_VREFP to VDDA_ADC1 when not using a positive external reference voltage.

If ADC1 is not used, connect all ADC1 terminals (ADC1_AIN[7:0], ADC1_VREFN, ADC1_VREFP, VDDA_ADC1, and VSSA_ADC) to the same ground as all VSS terminals.

12.3 Functional Description

12.3.1 FSM Sequencer Functional Description

The FSM sequencer supports up to 17 steps. One of the 17 steps is the Idle step which is always enabled and does not perform any analog-to-digital conversions. The other 16 steps always perform analog-to-digital conversions but they can be independently enabled or disabled.

The 16 steps which perform analog-to-digital conversions can individually be enabled and configured to operate as software enabled steps or hardware enabled steps. Each of these steps has their own programmable step configuration and step delay registers that allow users to configure the ADC operation on a per-step basis.

The FSM sequencer remains in the Idle step when it is not executing one of the 16 programmable steps. The Idle step does not have an enable bit in the step enable register or step delay register since this step does not perform any ADC operation.

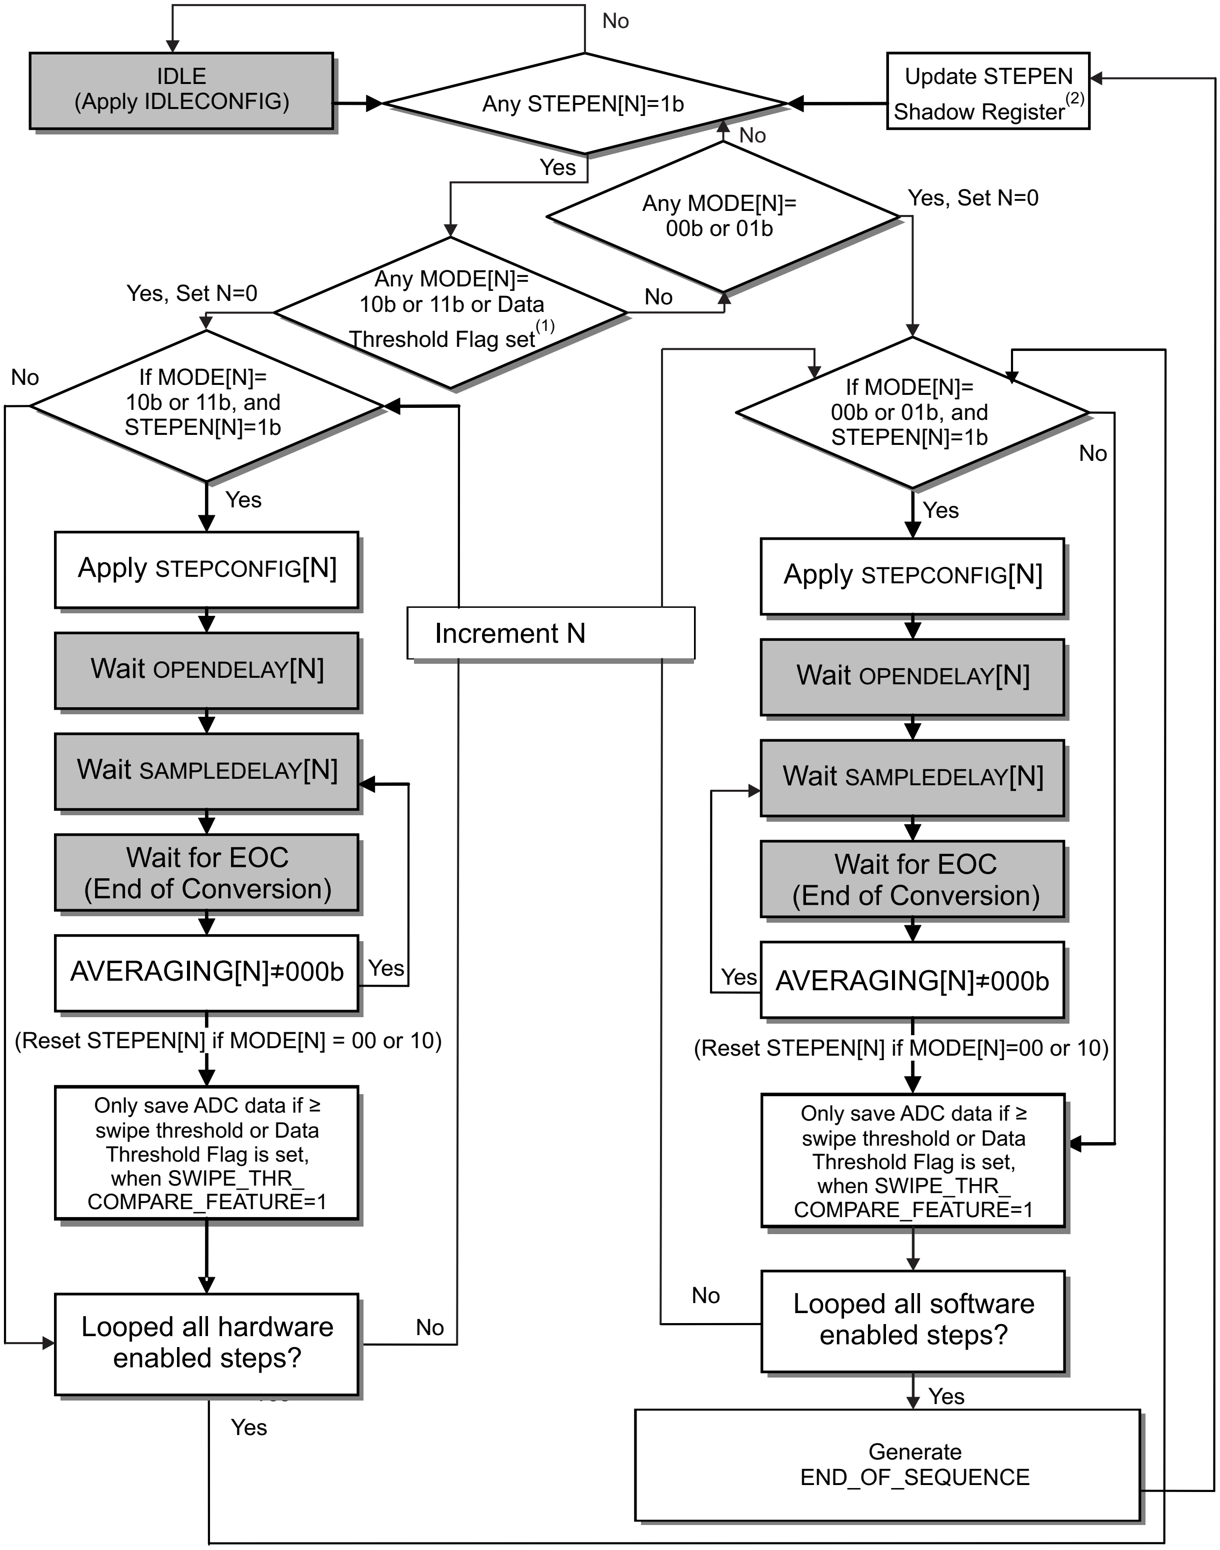
The FSM sequencer enters the Idle step and configures the AFE as defined by the idle configuration register immediately after ADC1 is enabled. It remains in the Idle step waiting for any of the 16 programmable steps to be enabled. When one or more step is enabled, the FSM sequencer will begin executing or skipping each step starting with the lowest and incrementing up through each step until the highest step has been executed or skipped. The FSM sequencer will execute enabled steps and skip disabled steps. Once all of the steps have been executed or skipped, the FSM sequencer will return to the Idle step or immediately begin repeating steps configured for continuous mode.

If the swipe threshold compare feature is enabled, the ADC output data will be compared to one of four swipe threshold registers. If the ADC output data value is lower than the swipe threshold, the ADC data is discarded (not saved in the FIFO), and the FSM sequencer continues to the next step. Once any step has reached or exceeded its swipe threshold, the FSM sequencer will save the ADC output data from the current step and all future steps without comparing ADC output data to the swipe threshold.

An end_of_sequence interrupt can be generated after the last enabled step has been executed. If any software enabled steps are configured for continuous operation and they are still enabled when the FSM sequencer has incremented through all the steps, the FSM sequencer will start the sequence again with the first enabled step. Hardware enabled steps are mapped to a hardware event and will need the hardware event to occur before being scheduled.

Figure 12-2 illustrates how the FSM sequencer works. Each shaded box represents a FSM state. **Note**: Figure 12-2 does not represent the number of adc_clk cycles required by each state since some states implement user programmable delays that may require more than one adc_clk cycle to complete.

Figure 12-2. FSM Sequencer



---

(1) A hardware event can be triggered by an external event or start of swipe interrupt, but the Data Threshold Flag is only set with the start of swipe interrupt and is only cleared when ADC1 is disabled.

(2) The STEPEN shadow register is updated after the FSM sequencer schedules the last step in order to queue up the next step.

12.3.1.1 Step Enable

A step is enabled or disabled via the STEPEN register.

The system software should only write to the STEPEN register when ADC1 is disabled or the FSM sequencer in in the Idle step. Therefore, it may be necessary to disable ADC1 before updating the STEPEN register if the FSM sequencer is executing back-to-back steps where it never enters the Idle step.

12.3.1.2 Step Configuration

12.3.1.2.1 One-Shot (Single) or Continuous Mode

Each step can be configured, via the least significant bit of the MODE bit-field in the respective STEPCONFIGx register, to operate in one-shot or continuous mode. Steps configured for one-shot mode will perform a single conversion before being disabled by the FSM sequencer. Steps configured for continuous mode will automatically be re-enabled by the FSM sequencer after each conversion until disabled by software.

12.3.1.2.2 Software- or Hardware-Enabled Steps

The user can configure each step to begin immediately after the step is enabled by software (SW Enabled), or wait for a hardware event to occur (HW Enabled). One of two sources can be selected for the hardware event.

One option is an internal comparator that compares the value of ADC output data to the value programmed into one of four swipe threshold registers. The hardware event will be triggered if the ADC output data value is greater than or equal to the selected swipe threshold when this option is selected. When using this option, an internal Data Threshold Flag will be set once the hardware event has occurred and this flag tells the FSM sequencer to continuously repeat all HW Enabled steps until ADC1 is disabled.

The other option is the EXT_HW_TRIGGER input signal which can be sourced from a device input terminal. When this option is selected, the hardware event will be triggered after the EXT_HW_TRIGGER input signal transitions from low to high and is held high for a period greater than two cycles of ocp_clock. This hardware event will only schedule one complete sequence, even for continuous mode. If HW Enabled steps need to be executed again, a new hardware event must be generated after the previously triggered sequence has completed.

The EXT_HW_TRIGGER input cannot be used as a hardware event when the FSM sequencer is configured to use the start of swipe interrupt as a hardware event.

Each step can be configured to operate in SW Enabled mode or HW Enabled mode independently via the most significant bit of the MODE bit-field in the respective STEPCONFIGx register. However, the hardware event source is applied globally to all HW Enabled steps and configured via the CTRL register.

12.3.1.2.3 Averaging of Samples

Each step can be configured, via the respective STEPCONFIGx register, to sample an input 1, 2, 4, 8, or 16 times and provide an average data value. If a step is configured to sample more than once, the additional samples are taken back-to-back immediately after the first sample. However, Open Delay is only applied to the first sample while Sample Delay is applied to all samples. Once the last sample has been taken the average data value will be stored in the FIFO unless the swipe threshold compare feature is enabled and the average data value is less than the swipe threshold.

12.3.1.2.4 Preamplifier Gain Control

Four differential preamplifiers with a programmable voltage gain of 12, 14, 16, or 18 were added to ADC1 as one of several magnet card reader enhancements. Each step provides individual gain control for each preamplifier via the respective STEPCONFIGx register.

12.3.1.2.5 Swipe Threshold Compare Feature

The swipe threshold compare feature is another magnet card reader enhancement. When this feature is enabled, via the respective STEPCONFIGx register, the FSM sequencer will automatically discard ADC data until it has exceeded a programmable swipe threshold value.

An internal Data Threshold Flag will be set once this hardware event has occurred and this flag tells the FSM sequencer to continuously repeat all HW Enabled steps until ADC1 is disabled.

12.3.1.2.6 Analog Multiplexer Input Select

The AFE contains 4 analog multiplexers. Two 9-to-1 multiplexers are used to select the source connected to the positive input (INP) and negative input (INM) of the ADC. A 6-to-1 multiplexer is used to select the source connected to the positive reference input (ADC_REFP) of the ADC. A 4-to-1 multiplexer is used to select the source connected to the negative reference input (ADC_REFN) of the ADC.

Each step can be configured, via the respective STEPCONFIGx register, to select the appropriate ADC input sources. For more information, refer to the ADC1 AFE Functional Block Diagram (Figure 12-5) and the STEPCONFIG register field descriptions.

12.3.1.2.7 Differential Control

ADC1 supports differential inputs and each step can be configured, via the respective STEPCONFIGx register, to select single-ended input mode or differential input mode.

Each enabled step should be configured for Differential mode when the AFE preamplifiers are not bypassed. Refer to the CRTL register field descriptions for information related to bypassing the AFE preamplifiers.

12.3.1.2.8 FIFO Select

ADC1 contains two FIFOs and each step can be configured, via the respective STEPCONFIGx register, to store its ADC data into either FIFO.

12.3.1.2.9 Range Check Interrupt Enable

Each step can be configured, via the respective STEPCONFIGx register, to compare the value of ADC data to high and low limits programmed in the ADCRANGE register. The out-of-range interrupt is generated if the value of ADC data is greater than the value of THR_HIGH_RANGE_DATA or less than the value of THR_LOW_RANGE_DATA. Refer to the ADCRANGE register field descriptions for information related to setting the high and low limits that trigger the out-of-range interrupt.

12.3.1.2.10 Swipe Threshold Register Pointer

ADC1 provides four swipe threshold registers and each step can be configured, via the respective STEPCONFIGx register, to use one of these four swipe thresholds when the swipe threshold compare feature is enabled.

12.3.1.3 Open Delay and Sample Delay

The FSM sequencer provides two programmable delays for each step. Open Delay is used to control when the acquisition begins after the step starts and Sample Delay is used to control the acquisition period. Delays for each of the 16 steps can be configured independently via the respective STEPDELAYx register.

12.3.1.3.1 Open Delay

Open Delay defaults to a value of zero which causes the acquisition period to begin as soon as the step starts. The start of the acquisition period can be delayed one adc_clk clock period for each incremental value of Open Delay.

12.3.1.3.2 Sample Delay

Sample Delay defaults to a value of zero which causes the acquisition period to be equal to two adc_clk clock periods. The acquisition period can be extended one adc_clk clock for each incremental value of Sample Delay.

When the AFE preamplifiers are not bypassed, the value of Sample Delay must be configured to provide a minimum acquisition period of 0.6 us which provides enough time for the preamplifiers outputs to settle. When the AFE preamplifiers are bypassed, the value of Sample Delay should be configured to provide enough time for the respective external voltage source to completely charge the AFE input capacitance during the acquisition period.

12.3.1.4 Interrupts

ADC1 has 9 internal events that can trigger an interrupt to the processor. These events are logically or’ed together to produce a single interrupt to the processor. The user can individually enable or disable each interrupt source via the IRQEN_SET and IRQEN_CLR registers. Once an interrupt is generated, the IRQSTS register can be read to determine which interrupt source(s) interrupted the processor. The interrupt source(s) can be cleared by writing a ‘1’ to the corresponding bit of the IRQSTS register.

12.3.1.4.1 End of Sequence

An END_OF_SEQUENCE interrupt is generated after the FSM sequencer completes the last enabled step.

12.3.1.4.2 FIFO Threshold

Each FIFO has the ability to generate an interrupt when the FIFO word count has reached a programmable threshold value. The FIFO0_THR/FIFO1_THR interrupts are generated when the value of FIFO0COUNT/FIFO1COUNT registers equals the word count threshold programmed in the respective FIFO0THR/FIFO1THR registers.

12.3.1.4.3 FIFO Overrun and Underflow

Each FIFO also has the ability to generate overrun and underflow interrupts. To clear a FIFO underflow or FIFO overrun interrupt, the user should write a ‘1’ so the status bit. ADC1 does not recover from these conditions automatically. Therefore, software will need to disable and re-enable ADC1 after this occurs. Before user can turn the module back on, they must first check if the FSM sequencer is in the Idle step by reading the ADC_STATUS_REG register.

12.3.1.4.4 Out of Range

The OUT_OF_RANGE interrupt can be enabled or disabled on each step. If enabled, the ADC data value is compared to the low and high thresholds programmed in the global ADCRANGE register. The OUT_OF_RANGE interrupt is generated if the ADC data value is greater than the value programmed in THR_HIGH_RANGE_DATA or less than the value programmed in THR_LOW_RANGE_DATA.

12.3.1.4.5 Start of Swipe

The START_OF_SWIPE interrupt can be enabled or disabled on each step. If enabled, the ADC data value is compared to one of four swipe threshold registers. The START_OF_SWIPE interrupt is generated if the ADC data value is greater than or equal to the value programmed in the swipe threshold register being pointed to by the respective SWIPE_THR_REG_POINTER. This interrupt can be configured as a hardware event which can be used to trigger HW enabled steps.

12.3.1.5 DMA Requests

Each FIFO can be serviced by the processor or DMA. The user can individually enable or disable each FIFO DMA request via the DMAEN_SET and DMAEN_CLR registers.

A DMA request is generated when the value of FIFO0COUNT/FIFO1COUNT registers equals the word count threshold programmed in the respective DMA0REQ/DMA1REQ registers.

The DMA slave port allows for burst reads in order to effectively move the FIFO data. Refer to the DMA section for more information.

12.3.2 AFE Functional Description

The AFE contains a single 12-bit successive approximation ADC which can be connected to one of eight user selectable analog inputs for each step executed by the FSM sequencer. There is also an option to configure the ADC to operate in differential mode where it samples the differential voltage applied to two of eight user selectable analog inputs. When operating in differential mode, the user also has the option of routing the differential input signal through a programmable gain preamplifier.

The ADC sits idle until the FSM sequencer sends a Start of Conversion (SOC) pulse. Once the FSM sequencer sends a SOC pulse to the ADC, it begins sampling the analog input signal on the rising edge of SOC and continues sampling the analog input signal one cycle of adc_clk after the falling edge of SOC. The SOC pulse width will be the value of Sample Delay plus one adc_clk periods, so the total ADC acquisition time will be the value of Sample Delay plus two adc_clk periods. The ADC captures the analog input signal at the end of the acquisition period and starts conversion, which requires thirteen adc_clk periods to digitize the sampled input. An EOC signal is returned to the FSM sequencer to indicate the digital data is ready.

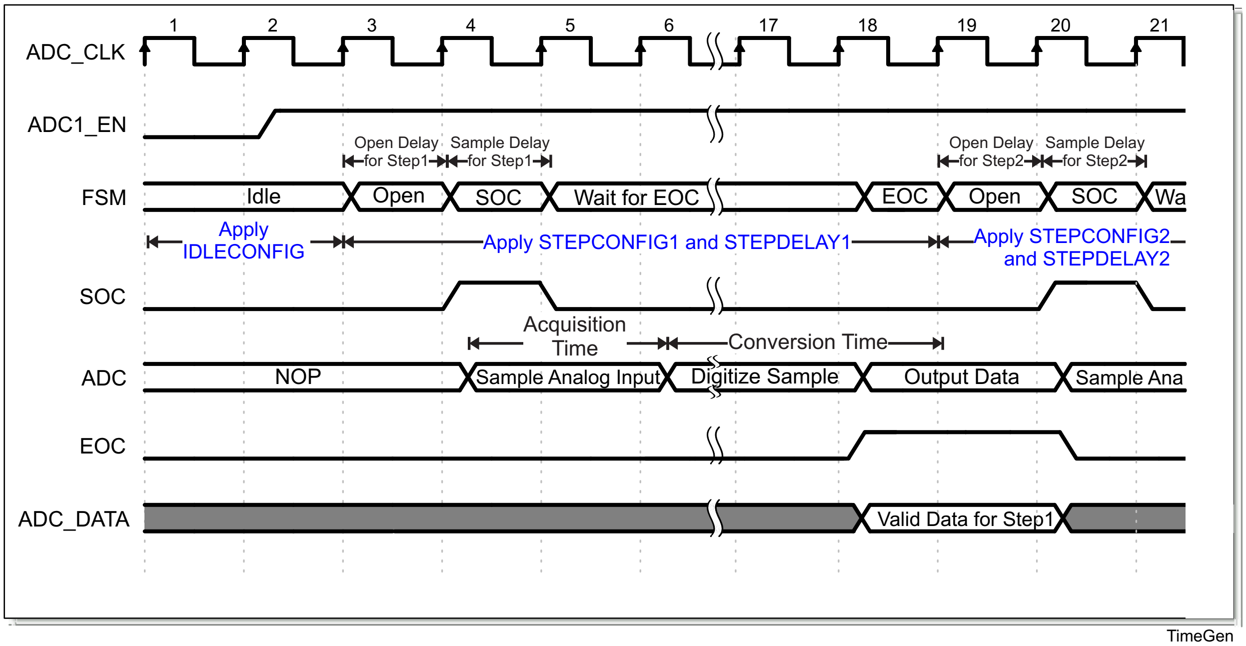
The ADC output is positive binary weighted data ranging from 0 to (2^{12} - 1). When configured for single-ended mode, ADC output data values 0 to (2^{12} - 1) represents a corresponding input voltage that ranges from the ADC negative reference (REFM) voltage to the ADC positive reference (REFP) voltage. When configured for differential mode, ADC output data values 0 to ((2^{12}/2) - 1) represents a corresponding negative differential input voltage that ranges from the ADC REFP voltage to the ADC REFM voltage and output data values (2^{12}/2) to (2^{12} - 1) represents a corresponding positive differential input voltage that ranges from the ADC REFM voltage to the ADC REFP voltage.

Using the minimum values of Open Delay and Sample Delay, the ADC can sample an analog input every 15 adc_clk periods.

Figure 12-3 illustrates the operation of the FSM sequencer and ADC, with indicators showing when the hardware configuration defined by STEPCONFIGx and STEPDELAYx registers are applied.

Figure 12-3 assumes both steps shown are software enabled with averaging turned off, an OPENDELAY value of 1, and SAMPLEDELAY value of 0. The analog input is sampled for the duration of the SOC pulse plus one cycle of the ADC_CLK. If the value of OPENDELAY were 0, it would appear as if the time associated with the Open portion of the FSM waveform would be removed from all the waveforms.

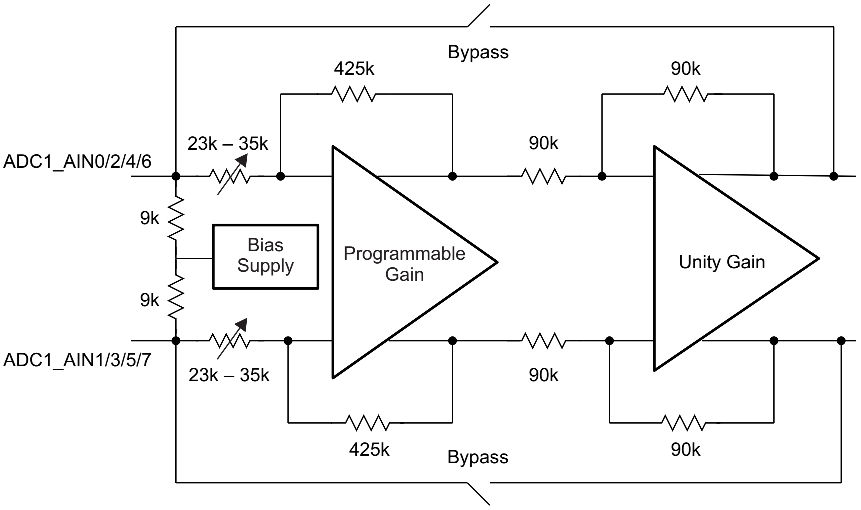
Figure 12-3. Example Timing Diagram for FSM Sequencer



12.3.2.1 AFE Functional Block Diagram

The AFE has 8 analog inputs which can be configured as either singled-ended or differential inputs to the ADC. Each analog input has an internal bias resistor connected to a mid-supply voltage source of VDDA_ADC1 divided by 2 that is shared with the other input associated with the preamplifier. A schematic of the input bias resistors, bias supply, and preamplifier is shown in Figure 12-4.

Figure 12-4. Input Bias Resistors, Bias Supply, and Preamplifier Schematic



NOTE: The resistor values shown are typical values.

The four preamplifiers have individual programmable voltage gain of 12, 14, 16, or 18.

If the preamplifiers are not bypassed, the ADC must be configured to operate in differential mode with one the following four input topologies. ADC1_AIN0 paired with ADC1_AIN1 where ADC1_AIN0 is the positive input and ADC1_AIN1 is the negative input to Preamplifier1. ADC1_AIN2 paired with ADC1_AIN3 where ADC1_AIN2 is the positive input and ADC1_AIN3 is the negative input to Preamplifier2. ADC1_AIN4 paired with ADC1_AIN5 where ADC1_AIN4 is the positive input and ADC1_AIN5 is the negative input to Preamplifier3. ADC1_AIN6 paired with ADC1_AIN7 where ADC1_AIN6 is the positive input and ADC1_AIN7 is the negative input to Preamplifier4. The differential input impedance of each preamplifier is 18 kohms biased to VDDA_ADC1 divided by 2 with a 22k-50k ohm source.

If the preamplifiers are bypassed, the user may configure a step to use any 1 of the 8 inputs when operating in single-ended mode or any 2 of the 8 inputs when operating in differential mode. However, the effect of the bias resistors and bias supply on the attached voltage source(s) should be considered when using ADC1 as a general purpose ADC. Each internal bias supply has a high output impedance when turned off which will be the case when bypassing the preamplifiers. In this use case, the majority of the input leakage current from any of the analog inputs will be based on the external voltage source connected to the other input associated with the preamplifier. For example, the ADC would measure 0.975 volts on ADC1_AIN1 if it were connected to a 1.0 volt, 1 kohm source while ADC1_AIN2 is connected to a 0.5 volt, 1 kohm source. The error caused by the internal bias resistors can be minimized by connecting the analog inputs to low impedance voltage sources or leaving the other input associated with the preamplifier open-circuit.

Figure 12-5. AFE Functional Block Diagram

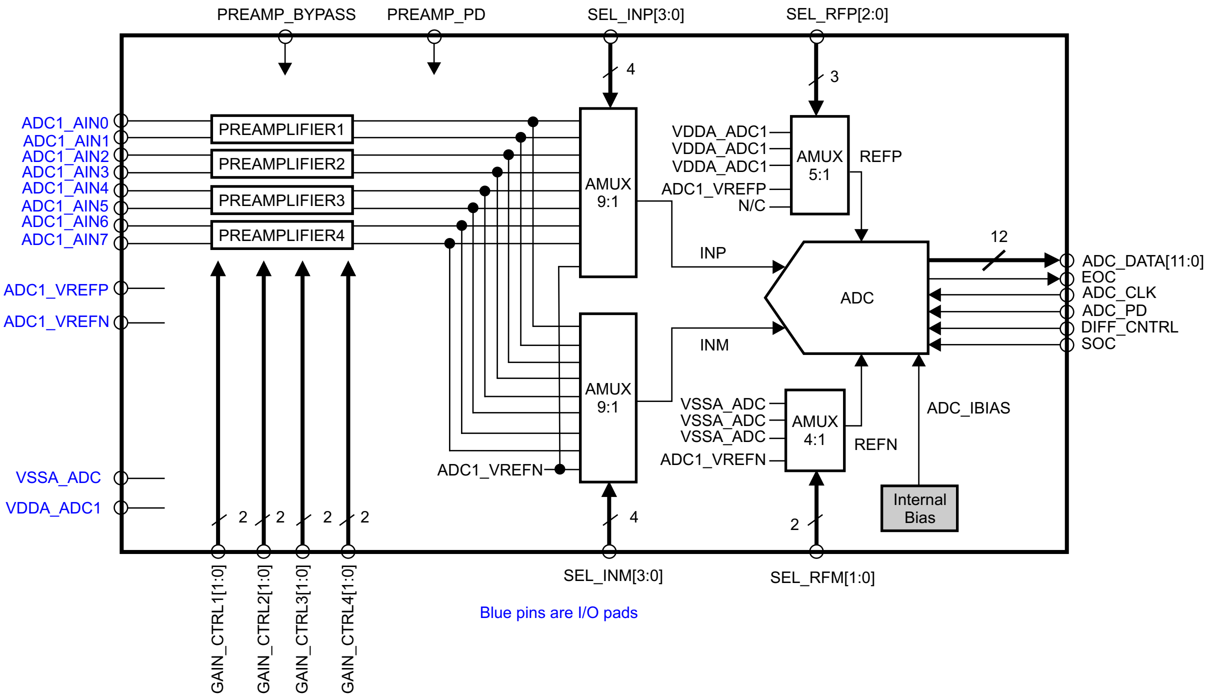


Table 12-4. ADC1 AFE Signal List (see Figure 12-5)

Signal	Type	Function
ADC_CLK	In	ADC clock input.
ADC_DATA[11:0]	Out	Digital data outputs.
ADC_PD	In	ADC power down input, active high.
ADC1_AIN0 (1)	In	Analog input 1.
ADC1_AIN1 (1)	In	Analog input 2.
ADC1_AIN2 (1)	In	Analog input 3.
ADC1_AIN3 (1)	In	Analog input 4.
ADC1_AIN4 (1)	In	Analog input 5.
ADC1_AIN5 (1)	In	Analog input 6.
ADC1_AIN6 (1)	In	Analog input 7.
ADC1_AIN7 (1)	In	Analog input 8.
ADC1_VREFN (1)	In	ADC negative reference input.
ADC1_VREFP (1)	In	ADC positive reference input.
DIFF_CNTRL	In	Differential control input, active high.
EOC	Out	End of Conversion output, active high.
GAIN_CTRL1 [1:0]	In	Gain control inputs for preamplifier 1.
GAIN_CTRL2 [1:0]	In	Gain control inputs for preamplifier 2.
GAIN_CTRL3 [1:0]	In	Gain control inputs for preamplifier 3.
GAIN_CTRL4 [1:0]	In	Gain control inputs for preamplifier 4.
PREAMP_PD	In	Preamplifier power down input, active high.
PREAMP_BYPASS	In	Preamplifier bypass input, active high.
SEL_RFP[2:0]	In	REFP multiplexer control inputs to select the ADC positive reference voltage.
SEL_RFM[1:0]	In	REFM multiplexer control inputs to select the ADC negative reference voltage.
SEL_INP[3:0]	In	INP multiplexer control inputs to select the ADC positive analog input.
SEL_INM[3:0]	In	INM multiplexer control inputs to select the ADC negative analog input.
SOC	In	Start of conversion input, active high.
VDDA_ADC1 (1)	Power	ADC1 Analog Power
VSSA_ADC (1)	Power	ADC0 and ADC1 Analog Ground

(1) Signal connects to device terminals.

12.3.3 FIFOs and DMA

12.3.3.1 FIFOs

The processor can read ADC data directly from the FIFO by using the respective FIFO0DATA or FIFO1DATA register. The internal logic will pop the next data from the FIFO and increment the FIFO read pointers.

The FIFO data will no longer be accessible after ADC1 is disabled because the FIFO pointers are reset. Therefore, it is important to read all FIFO data before disabling ADC1.

12.3.3.2 DMA

ADC1 has a dedicated slave port for the DMA which allows it to perform continuous burst reads when accessing the FIFOs.

Each FIFO has its own DMA request which can be enabled via the DMAEN_SET register and disabled via the DMAEN_CLR register.

The first DMA request is generated after the FIFO leaves the EMPTY state and fills to the level programmed in the DMA_REQUEST_LEVEL bit field of the respective DMA0REQ or DMA1REQ register.

Subsequently, a new DMA request is automatically generated on the next clock cycle after the current DMA access completes if the previous DMA access did not empty the FIFO.

12.3.4 Power Management

ADC1 supports smart-idle mode where it shares slave idle/request handshaking with the PRCM that allows ADC1 to automatically enter an idle state when it is disabled or the FSM sequencer is in the Idle state with all the steps disabled.

Software also has the option to directly turn off power to the ADC by setting the ADC_POWER_DOWN bit in the CTRL register.

The preamplifiers in the AFE can be powered down by setting the PREAMP_PD bit in the CTRL register. The preamplifiers are automatically powered down when they are bypassed by setting the PREAMP_BYPASS bit in the CTRL register.

It is the software’s responsibility to empty the FIFO before allowing ADC1 to enter the idle state. There should be no activity on the DMA slave port or MMR slave ports while ADC1 is in the idle state.

12.3.5 Magnetic Card Operation (Use Cases)

The AFE implemented in ADC1 provides four differential inputs with integrated preamplifiers that can be connected directly to magnetic heads to implement a magnetic card reader.

12.3.5.1 Use Case 1

Continuously sample a single differential analog input while comparing the ADC output data to a programmable swipe threshold value to detect a card swipe, then read one or more tracks of card data.

The FSM sequencer should be configured to enable one software enabled continuous step that samples the appropriate differential input with its swipe compare feature enabled (bit 11 in STEPCONFIGx register). If more than one track is being read from the card after the swipe is detected, the FSM sequencer must also be configured with hardware enabled steps that sample the differential inputs associated with the other tracks.

This configuration will cause the FSM sequencer to continuously sample the input being sampled by the software enabled step and compare the ADC output data to the swipe threshold value that is programmed in one of four threshold registers. The appropriate threshold register is selected with the swipe threshold register pointer (bits 31:30 in STEPCONFIGx register). If the ADC output data corresponding to the analog input is less than swipe threshold, the ADC output data is discarded and the analog input is sampled again.

When the analog input produces an ADC output data value that is equal to or greater than the swipe threshold, the ADC output data will be stored in the FIFO and the start of swipe interrupt will be generated if enabled. The start of swipe interrupt can be configured to automatically enable the hardware enabled steps which sample the other differential inputs.

This example describes how a single track on the magnetic card can be used to detect a card swipe which causes all tracks of the magnetic card to be continuously sampled and resulting ADC output data stored in the FIFO until FSM sequencer is disabled (bit 0 in CTRL register).

The FSM sequencer will perform the following operations to implement this use case:

Sample input associated with software enabled step (if data < swipe threshold, discard data),

Sample input associated with software enabled step until data >= swipe threshold (save data, generate start of swipe interrupt),

Sample inputs associated with hardware enabled steps then sample input associated with software enabled step (save data in the order samples were taken),

Repeat previous sequence until ADC1 is disabled.

12.3.5.2 Use Case 2

Continuously sample all four differential analog inputs while comparing the ADC output data of each sample to its programmable swipe threshold value to detect a card swipe, then read four tracks of card data.

The FSM sequencer should be configured to enable four software enabled continuous steps such that each step samples one of the four differential inputs with each step having its swipe compare feature enabled (bit 11 in STEPCONFIGx register).

This configuration will cause the FSM sequencer to continuously sample all four differential inputs and compare the ADC output data from each step to its respective swipe threshold value that is programmed in one of four threshold registers. The appropriate threshold register is selected with the swipe threshold register pointer (bits 31:30 in STEPCONFIGx register). If the ADC output data corresponding to the analog input is less than swipe threshold, the ADC output data is discarded and the next analog input is sampled.

When any of the four analog inputs produces an ADC output data value that is equal to or greater than its respective swipe threshold, the ADC output data from that step will be stored in the FIFO and the start of swipe interrupt will be generated if enabled. The FSM sequencer will continue executing the same sequence of steps with the next step being the one that follows the step which triggered the swipe interrupt. The ADC output data from each step following the swipe interrupt will be stored in the FIFO.

This example describes how all four tracks on the magnetic card can be used to detect a card swipe which causes all tracks of the magnetic card to be continuously sampled and resulting ADC output data stored in the FIFO until FSM sequencer is disabled (bit 0 in CTRL register).

The FSM sequencer will perform the following operations to implement this use case:

Sample input associated with first software enabled step (if data < swipe threshold, discard data),

Sample input associated with second software enabled step (if data < swipe threshold, discard data),

Sample input associated with third software enabled step (if data < swipe threshold, discard data),

Sample input associated with forth software enabled step (if data < swipe threshold, discard data),

Repeat above sequence of steps until data >= swipe threshold (save data, generate start of swipe interrupt),

Resume the same sequence of steps (save data in the order samples were taken),

Continue until ADC1 is disabled.

12.3.6 Simultaneous Control of ADC0

ADC1 can be configured to control the AFE in ADC0. This feature is enabled by setting the SIMULTANEOUS_CTRL bit in the CTRL register. When enabled, the ADC1 FSM sequencer sources the AFE control signals to both ADC0 AFE and ADC1 AFE. This causes the ADC0 AFE to perform the same operations as ADC1 AFE, but ADC0 AFE will be sampling ADC0 analog inputs while ADC1 AFE is sampling ADC1 analog inputs.

The ADC output data from ADC0 AFE is returned to the ADC1 FSM sequencer which stores this data in FIFO1 while storing ADC output data from ADC1 AFE in FIFO0. The FSM sequencer packs the 12 bits of ADC data and optional 4-bit step ID from both AFEs into a single 32-bit value when the processor or DMA reads FIFO0 when simultaneous control mode is enabled.

The ADC output data from ADC0 AFE is returned to the ADC1 FSM sequencer which stores this data in FIFO1 while storing ADC output data from ADC1 AFE in FIFO0. The FSM sequencer packs the 12 bits of ADC data and optional 4-bit step ID from both AFEs into a single 32-bit value when the processor or DMA reads FIFO0 when simultaneous control mode is enabled.

Figure 12-6 and Table 12-5 describe the contents of the ADC1_FIFO0DATA read by the processor or DMA when ADC1 is operating in simultaneous control mode.

For a description of ADC1_FIFO0DATA when ADC1 is not operating in simultaneous control mode, see Section 12.4.1.55.

Figure 12-6. ADC1_FIFO0DATA Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADC0CHNLID				ADC0DATA											
R-0h				R-0h											

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADC1CHNLID				ADC1DATA											
R-0h				R-0h											

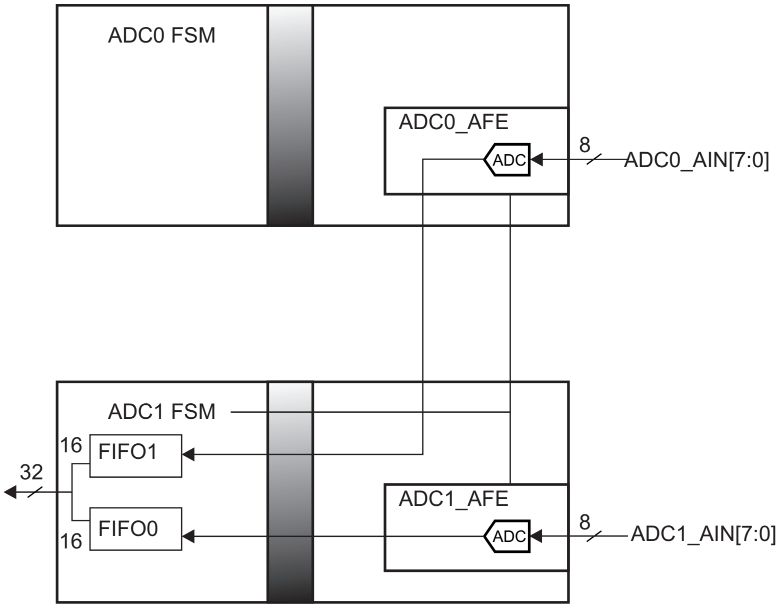
Table 12-5. ADC1_FIFO0DATA Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	ADC0CHNLID	R	0h	ADC0 Step ID Tag of step that captured ADC0 data. These bits will be 0000b if STEP_ID_TAG = 0b.
27-16	ADC0DATA	R	0h	12-bit ADC0 data.
15-12	ADC1CHNLID	R	0h	ADC1 Step ID Tag of step that captured ADC1 data. These bits will be 0000b if STEP_ID_TAG = 0b.
11-0	ADC1DATA	R	0h	12-bit ADC1 data.

All DMA requests and FIFO interrupts are initiated by the ADC1 FSM sequencer based on the conditions of FIFO0 data only. All DMA requests and FIFO interrupts related to FIFO1 should be disabled

Below is a block diagram for the integration of ADC0 and ADC1 when operating in simultaneous mode.

Figure 12-7. Integration of ADC0 and ADC1 in Simultaneous Mode



12.4 Registers

ADC1 only supports 32-bit aligned read/write register accesses.

12.4.1 ADC1 Registers

Table 12-6 lists the memory-mapped registers for the ADC1. All register offset addresses not listed in Table 12-6 should be considered as reserved locations and the register contents should not be modified.

12.4.1.51 ADC1_DMA0REQ Register (offset = ECh) [reset = 0h]

ADC1_DMA0REQ is shown in Figure 12-58 and described in Table 12-57.

Figure 12-58. ADC1_DMA0REQ Register

Table 12-57. ADC1_DMA0REQ Register Field Descriptions

Bit	Field	Type	Reset	Description
5-0	DMA_REQUEST_LEVEL	R/W	0h	Number of words in FIFO0 before generating a DMA request (program to value minus 1).

12.4.1.52 ADC1_FIFO1COUNT Register (offset = F0h) [reset = 0h]

ADC1_FIFO1COUNT is shown in Figure 12-59 and described in Table 12-58.

Figure 12-59. ADC1_FIFO1COUNT Register

Table 12-58. ADC1_FIFO1COUNT Register Field Descriptions

Bit	Field	Type	Reset	Description
6-0	WORDS_IN_FIFO1	R	0h	Number of words currently in the FIFO1.

12.4.1.53 ADC1_FIFO1THR Register (offset = F4h) [reset = 0h]

ADC1_FIFO1THR is shown in Figure 12-60 and described in Table 12-59.

Figure 12-60. ADC1_FIFO1THR Register

Table 12-59. ADC1_FIFO1THR Register Field Descriptions

Bit	Field	Type	Reset	Description
5-0	FIFO1_THR_LEVEL	R/W	0h	Program the desired FIFO1 data sample level to reach before generating interrupt to CPU (program to value minus 1).

12.4.1.54 ADC1_DMA1REQ Register (offset = F8h) [reset = 0h]

ADC1_DMA1REQ is shown in Figure 12-61 and described in Table 12-60.

Figure 12-61. ADC1_DMA1REQ Register

Table 12-60. ADC1_DMA1REQ Register Field Descriptions

Bit	Field	Type	Reset	Description
5-0	DMA_REQUEST_LEVEL	R/W	0h	Number of words in FIFO1 before generating a DMA request (program to value minus 1).

12.4.1.55 ADC1_FIFO0DATA Register (offset = 100h) [reset = 0h]

ADC1_FIFO0DATA is shown in Figure 12-62 and described in Table 12-61.

Figure 12-62. ADC1_FIFO0DATA Register

Table 12-61. ADC1_FIFO0DATA Register Field Descriptions

Bit	Field	Type	Reset	Description
19-16	ADCCHNLID	R	0h	Optional ID tag of channel that captured the data. If tag option is disabled, these bits will be 0.
15-12	RESERVED	R		
11-0	ADCDATA	R	0h	12 bit sampled ADC converted data value stored in FIFO0.

12.4.1.56 ADC1_FIFO1DATA Register (offset = 200h) [reset = 0h]

ADC1_FIFO1DATA is shown in Figure 12-63 and described in Table 12-62.

Figure 12-63. ADC1_FIFO1DATA Register

Table 12-62. ADC1_FIFO1DATA Register Field Descriptions

Bit	Field	Type	Reset	Description
19-16	ADCCHNLID	R	0h	Optional ID tag of channel that captured the data. If tag option is disabled, these bits will be 0.
15-12	RESERVED	R		
11-0	ADCDATA	R	0h	12 bit sampled ADC converted data value stored in FIFO1.

Display Subsystem (DSS)

This chapter describes the display subsystem (DSS) of the device.

NOTE: The Display Subsystem (DSS) is not supported for the AMIC120.

Topic **Page**

13.1 Introduction

13.1.1 DSS Features

The general features of the DSS module include:

- Display Controller
  - Display Modes
    - Programmable pixel memory formats (Palletized: 1, 2, 4, 8-bit per pixel; RGB 16, and 24-bit per pixel; and YUV 4:2:2)
    - Programmable display size (up to 2048 x 2048)
    - 256 x 24-bit entries palette in RGB
    - Programmable pixel rate (up to 100 MHz)
  - Display Support
    - Four types of displays are supported: Passive and Active colors, Passive and Active monochromes.
    - 4-/8-bit Monochrome Passive panel interface support (15 grayscale levels supported using dithering block)
    - RGB 8-bit Color Passive panel interface support (3,375 colors supported for color panel using dithering block).
    - RGB 12/16/18/24-bit Active panel interface support (replicated or dithered encoded pixel values).
    - Remote Frame Buffer (embedded in the LCD panel) support through the RFBI module
    - Partial refresh of the remote frame buffer through the RFBI module
    - Partial display
    - Multiple cycles output format on 8/9/12/16bit interface (TDM)
  - Signal Processing
    - Overlay and Windowing support for one Graphics layer (RGB or CLUT) and two Video layers (YUV 4:2:2, RGB16 and RGB24)
    - RGB 24-bit support on the display interface, optionally dithered to RGB 18-bit pixel output + 6-Bit Frame rate Control (spatial and temporal)
    - Transparency color key (source and destination)
    - Synchronized buffer update
    - Gamma Curve Support
    - Multiple-buffer support
    - Cropping Support
    - Merge capability of the DMA FIFO for use by a single pipeline in case of DVFS
    - Color Phase rotation
  - Interrupt line and DMA line trigger signals
    - The LCD DMA is a secure transaction initiator on the L3 interconnect.
- Remote Frame Buffer Interface
  - Access to RFB's “direct MPU interface”
    - Sending commands to the RFB panel.
    - Sending data to the RFB panel, received from the Display controller or from the MPU (through the L4 OCP slave port)
    - Reading data/status from the RFB to the OCP slave port.
  - RFB interface
    - 8/9/12/16-bit parallel interface (up to QVGA@30fps at nominal voltage)
    - Two programmable configurations for two devices connected to the RFBI module.

    - Tearing Effect control logic (Horizontal Synchronization (HSync) and Vertical Synchronization (VSync) embedded in a single signal (TE) or using two signals (HS+VS)).
  - Data formats
    - Programmable pixel memory formats (12-, 16-, 18- and 24-bit-per-pixel modes in RGB format)
    - Programmable output formats on one/multiple cycles per pixel (data from Display controller and from L4) (TDM)
-

13.1.2 Unsupported Features

The display subsystem does not support the following features.

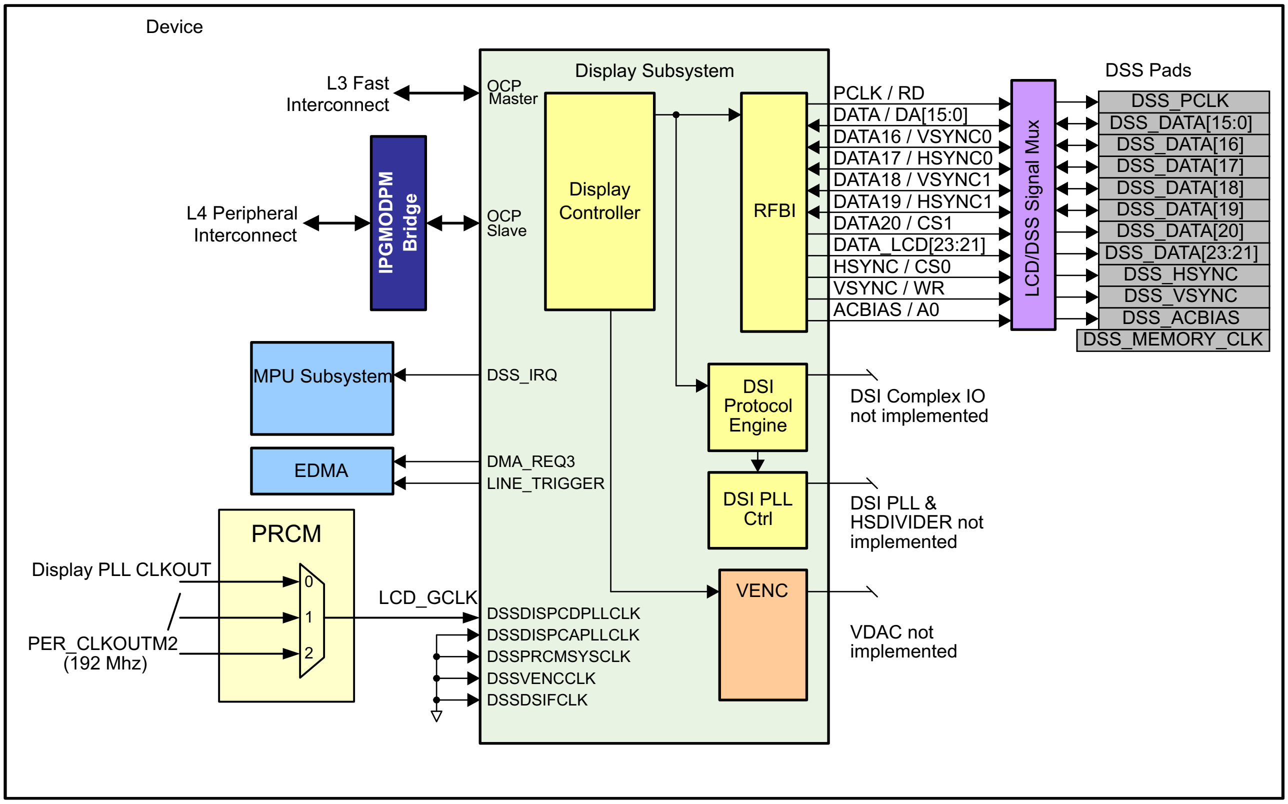
Table 13-1. Unsupported Display Subsystem Features

Feature	Reason
FlatLink Serial Display	SDI Complex I/Os not implemented
MIPI Serial Displays	DSI Complex I/Os not implemented
NTSC/PAL Displays	Video DAC not implemented
Rotation/Mirroring	No SDRAM rotation engine implemented on device

13.2 Integration

This device includes a Display Subsystem (DSS) that reads display data from external memory and drives several different types of LCD displays. The Display Subsystem integration is shown in Figure 13-1.

Figure 13-1. DSS Integration



13.2.1 DSS Connectivity Attributes

The general connectivity attributes for the DSS module are shown in Table 13-2.

Table 13-2. DSS Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3_GCLK (OCP master clock) PD_PER_L4LS_GCLK (OCP slave clock) PD_PER_LCD_GCLK (Functional clock)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Standby Smart Idle
Interrupt Requests	1 interrupt to MPU Subsystem (DSSINT)
DMA Requests	2 DMA requests to EDMA
Physical Address	L4 peripheral slave port

13.2.2 DSS Clock and Reset Management

The DSS module uses the OCP interface and multiple functional clocks. The L4 slave interface runs at half the frequency of the L3 Master interface. The functional clocks come from the device's display PLL rather than a dedicated DSI_PLL. When the display PLL is in bypass mode, its output is sourced by either CORE_CLKOUTM6 or PER_CLKOUTM2.

Table 13-3. DSS Clock Signals

Clock Signal	Maximum Frequency	Reference Source	Comments
DSSL3OCPIFCLK Master interface	200 MHz	CORE_CLKOUTM4	pd_per_l3_gclk from PRCM
DSSL3OCPIFENAB L3 phase clock enable used to create L4 clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk from PRCM
DSSPRCMSYSCLK Functional clock	N/A	N/A	DSI PLL source clock not needed since DSI PLL is not present
DSSDISPCAPLLCLK L3 phase clock enable used to create L4 clock	N/A	N/A	DSSDISPCDPLLCLK is default display controller clock source
DSSDISPCDPLLCLK(1)	200 MHz	Display PLL CLKOUT or PER_CLKOUTM2	pd_per_lcd_gclk from PRCM
DSSVENCCLK Video encoder functional clock	N/A	N/A	VENC not supported
DSSDSIFCLK DSI functional clock	N/A	N/A	DSI not supported

(1) The Display PLL CLKOUT can be used as a reference clock for other peripherals. If these other peripherals require the Display PLL CLKOUT to be configured for >200MHz, then the DSS must use the PER_CLKOUTM2 (192 MHz) and the pixel clock will be limited to a divisor of 192 MHz.

13.2.3 DSS Pin List

The display subsystem external interface pins are shown in Table 13-4. Pin function depends on the operating mode (bypass or RFBI). The DSSLCDDIR[2:0] control signals are used to control the pad OEN of the associated signals as shown.

Table 13-4. DSS Pin List

Pin Name	Pin Function	Type	Description	DSSLCDDIR Control Signal
dss_pclk	DISPC_PCLK / RFBI_RD	O	Pixel Clock / RFBI Read Enable	1
dss_data[15:0]	DISPC_DATA_LCD / RFBI_DA[15:0]	I/O/Z	Pixel Data Bus / RFBI Data	0
dss_data16	DISPC_DATA_LCD16 / RFBI_TE_VSYNC0	I/O/Z	Pixel Data Bus / RFBI Tearing Effect or Vertical Sync 0	2
dss_data17	DISPC_DATA_LCD17 / RFBI_HSYNC0	I/O/Z	Pixel Data Bus / RFBI Horizontal Sync 0	2
dss_data18	DISPC_DATA_LCD18 / RFBI_TE_VSYNC1	I/O/Z	Pixel Data Bus / RFBI Tearing Effect Vertical Sync 1	2
dss_data19	DISPC_DATA_LCD19 / RFBI_HSYNC1	I/O/Z	Pixel Data Bus / RFBI Horizontal Sync 1	2
dss_data20	DISPC_DATA_LCD20 / RFBI_CS1	O	Pixel Data Bus / RFBI Chip Select 0	1
dss_data[23:21]	DISPC_DATA_LCD[23:21]	O	Pixel Data Bus	1
dss_hsync	DISPC_HSYNC / RFBI_CS0	O	Horizontal Sync / RFBI Chip Select 0	1
dss_vsync	DISPC_VSYNC / RFBI_WR	O	Vertical Sync / RFBI Write Enable	1
dss_ac_bias_en	DISPC_ACBIAS / RFBI_A0	O	AC Bias Enable / RFBI Command/Data indicator	1

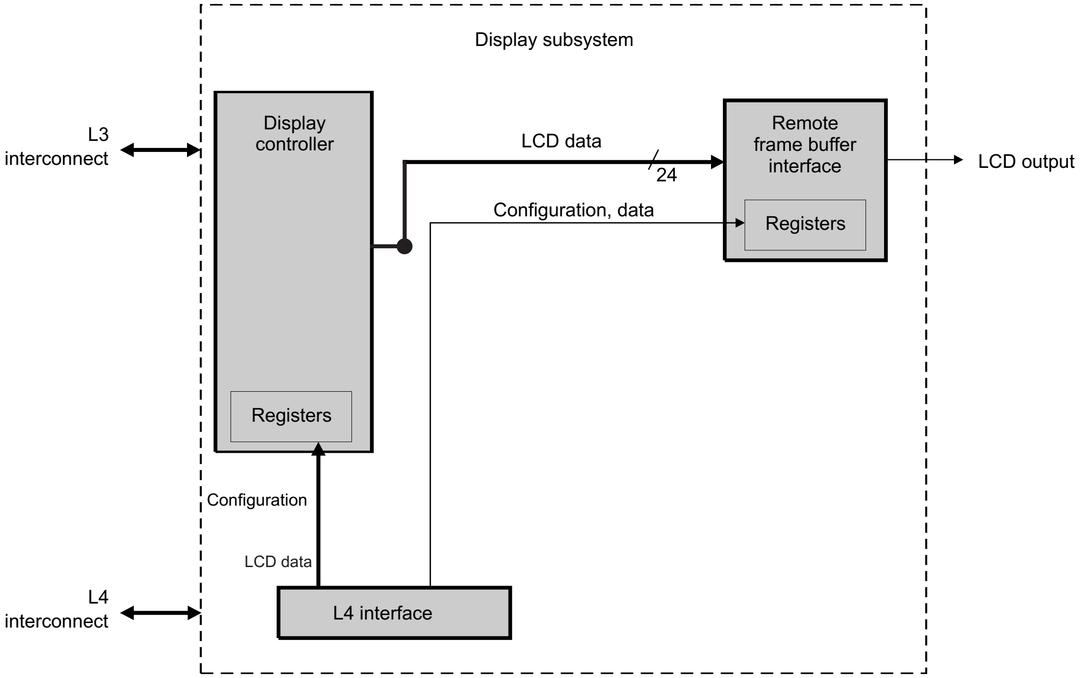
13.3 Functional Description

This section describes the functions of the LCD display support by describing the display controller and RFBI modules.

13.3.1 Block Diagram

Figure 13-2 is a schematic of the display subsystem.

Figure 13-2. Display Subsystem Full Schematic



13.3.2 Display Subsystem Environment

This section describes the two main functions handled by the display subsystem:

- LCD support
- TV display support

13.3.2.1 LCD Support

LCD panels can be connected to the display subsystem of the device using parallel and/or serial interfaces.

Table 13-5 provides more details on the supported interfaces to LCD panels, and the respective pad and signal configurations.

Table 13-5. LCD Interface Signals and Configurations

The parallel interface connectivity is detailed in Section 13.3.2.1.1, *Parallel Interface*.

13.3.2.1.1 Parallel Interface

In parallel interface, the paths of the display subsystem modules are the display controller and the RFBI.

The display controller provides the required control signals to interface the memory frame buffer (SDRAM or SRAM) directly to the external displays. The display controller is connected to the memory through the L3 interconnect and has its own DMA (with embedded FIFOs) to read data from the system memory. The L3 interconnect is the master port, while the L4 interconnect is the slave port of the display subsystem.

The display controller has two I/O pad modes at the module level:

- RFBI mode (RFBI enabled), which implements the MIPI DBI 2.0 protocol
- Bypass mode (RFBI disabled), which implements the MIPI DPI 1.0 protocol

The DSS.DISPC_CTRL[16:15] GPOUT[1:0] bits control selection of the display subsystem modules (see Table 13-6).

Table 13-6. I/O Pad Mode Selection

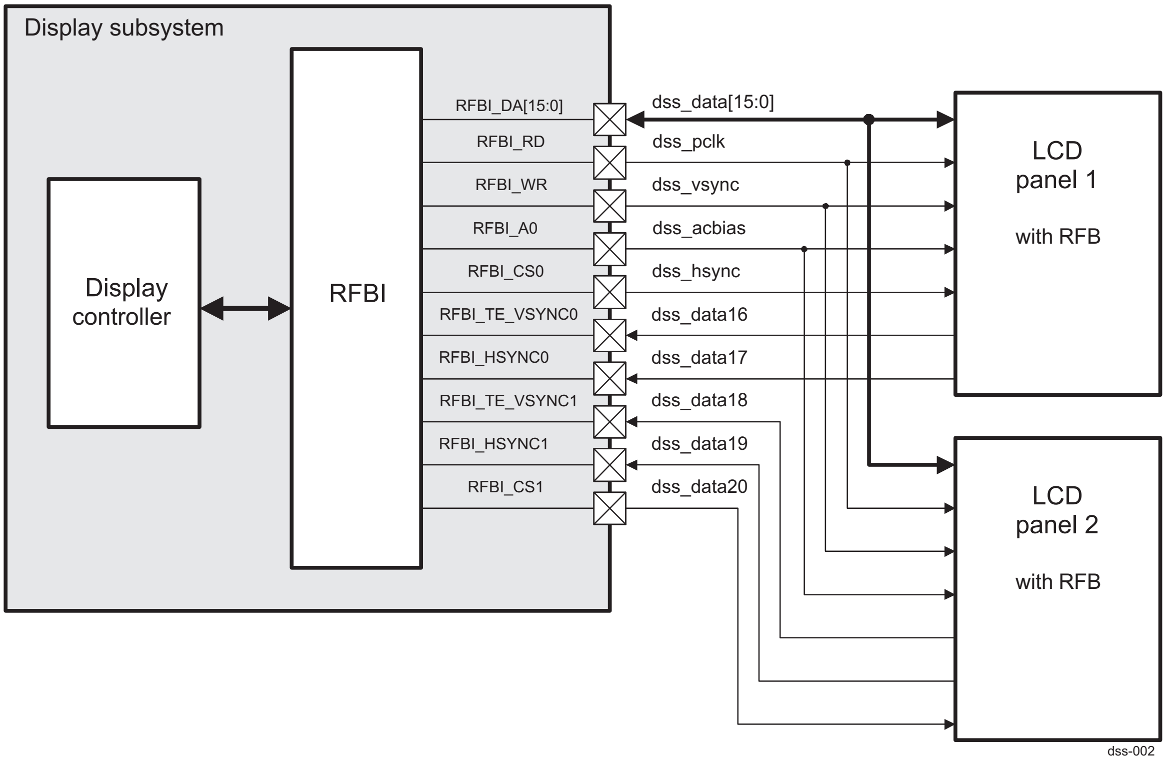
DSS.DISPC_CTRL[16] GPOUT1	DSS.DISPC_CTRL[15] GPOUT0	Mode
0	0	Reset
0	1	RFBI mode
1	0	Invalid
1	1	Bypass mode

The RFB of the LCD panel is connected directly to the RFBI module of the device. The RFBI controls the reads/writes from/to the RFB. The RFBI receives the output from the DISPC (which takes data from the memory) and generates the signals to control the LCD panel. Through the RFBI, the MPU can send commands or parameter/display data to the LCD panel and directly set the DISPC registers to read/write the data from/to the memory in the LCD panel. The RFBI can manage up to two LCD panels when the serial interface is not used.

13.3.2.1.1.1 Parallel Interface in RFBI Mode (MIPI DBI Protocol)

Figure 13-3 shows the LCD support parallel interface in RFBI mode (example for 16-bit data interface).

Figure 13-3. LCD Support Parallel Interface (RFBI Mode)



NOTE: Configure the DSS.RFBI_CTRL[3:2] CONFIG_SELECT bit field to drive signals for LCD 1 only, LCD 2 only, or both LCD 1 and LCD 2.

Table 13-7 describes the interface signals to/from the LCD panel in RFBI mode.

Table 13-7. LCD Interface Signals (RFBI Mode)

Signal Name	Type[1]	Description
RFBI_DA[15:0]	I/O	RFBI I/O data
RFBI_RD	O	Read access signal
RFBI_WR	O	Write access signal
RFBI_A0	O	Command/data selection signal
RFBI_CS0	O	Chip-select (CS) signal for LCD 1
RFBI_CS1	O	CS signal for LCD 2
RFBI_TE_VSYNC0	I	Tearing effect (TE) synchronization signal (TE or VSYNC for LCD panel 1)
RFBI_HSYNC0	I	HSYNC from LCD panel 1
RFBI_TE_VSYNC1	I	TE synchronization signal (TE or VSYNC for LCD panel 2)
RFBI_HSYNC1	I	HSYNC from LCD panel 2

[1] I = Input, O = Output, I/O = Input/Output

- RFBI_DA[15:0]: The pixel data comprises the RFBI pixel data (bits 15:0). A write/read command must be sent to the LCD panel to send/read the data.

  Before any data access, the application must send commands and parameters when it is necessary to configure an LCD panel. The data is used as input in read operations during production test and also to read the status of the registers in the LCD panel and pixels from the embedded frame buffer in the

LCD panel module. RFBI_DA is multiplexed at the chip-level boundary with dss_data [15:0].

- RFBI_RD: This is the read-enable signal used to indicate when a read from the embedded memory in the LCD panel is ongoing. The RFBI registers describe the behavior of the read signal (off/on/cycle time). The polarity of the read-enable signal is programmable. This signal is multiplexed at the chip-level boundary with dss_pclk. The read is used to get status/data information from the LCD panel.
- RFBI_WR: The write-enable signal is used to indicate when a write is ongoing. The RFBI registers describe the behavior of the write signal (off/on/cycle time). The polarity of the write-enable signal is programmable. This signal is multiplexed at the chip-level boundary with dss_vsync.
- RFBI_A0: The signal is asserted to indicate its status: Command or data. The polarity is programmable and the status of the signal depends on the RFBI registers written by the application (CMD/READ/STATUS/PARAM/PIXEL). The register in use by the hardware defines the status of RFBI_A0. The order of the writes/reads to the RFBI registers CMD/READ/STATUS/PARAM/PIXEL defines the transitions of A0. This signal is multiplexed at the chip-level boundary with dss_acbias.
- RFBI_CSx: The signal is the chip-select (CSx) asserted to indicate which LCD panel is selected and must be ready to receive/transmit commands and data. When RE or WE is on, CSx must not be changed (x = 0 for LCD panel 1; x = 1 for LCD panel 2). CS0 is multiplexed at the chip-level boundary with dss_hsync, and CS1 is multiplexed at the chip-level boundary with dss_data[20].
- RFBI_TE_VSYNCx: Based on the trigger mode selected, the signal is the TE pulse signal or the LCD panel VSYNC (vertical synchronization) pulse signal. RFBI_TE_VSYNCx is used by the TE logic as the synchronization signal to send the pixel to the LCD panel.

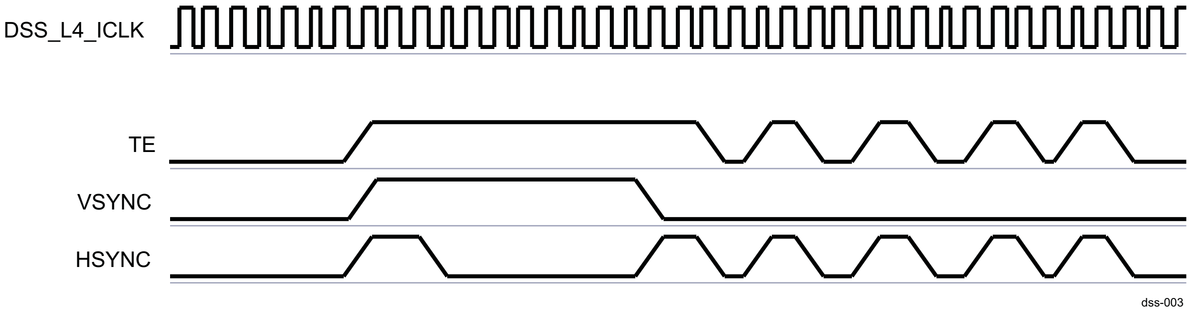
  To select the trigger mode, configure the DSS.RFBI_CONFIG_i[3:2] TRIGGER_MODE bit field (0x0: Internal trigger mode with the DSS.RFBI_CTRL[4] ITE bit, 0x1: External trigger mode with the TE signal RFBI_TE_VSYNCx, 0x2: External trigger mode with the RFBI_TE_VSYNCx, and RFBI_HSYNCx signals with the programmable line counter).

  These signals are multiplexed at the chip-level boundary with dss_data[16] (RFBI_TE_VSYNC0) and dss_data[18] (RFBI_TE_VSYNC1) (LCD panel 1: x = 0; LCD panel 2: x = 1).
- RFBI_HSYNCx: The HSYNC pulse signals indicate to the RFBI module when horizontal synchronization occurs. The polarity of the HSYNC signals is programmable. The minimum pulse width of the signal is two L4 cycles. RFBI_HSYNC is used by the TE logic as a synchronization signal to send the pixel to the LCD panel. These signals are multiplexed at the chip-level boundary with dss_data[17] (RFBI_HSYNC0) and dss_data[19] (RFBI_HSYNC1) (LCD panel 1: x = 0; LCD panel 2: x = 1).

13.3.2.1.1.1.1 Description of the TE Pulse Signal

The externally-generated TE synchronization signal is a logical OR or AND operation between the HSYNC and VSYNC signals (see Figure 13-4). The logical operation (OR or AND) depends on the HSYNC and VSYNC signals polarity. The VSYNC signal indicates to the RFBI module when vertical synchronization occurs; the HSYNC signal indicates to the RFBI module when horizontal synchronization occurs.

Figure 13-4. External Generation of TE Signal Based on Logical OR Operation Between HSYNC and VSYNC (Active-High)



The RFBI module detects the VSYNC and HSYNC pulses embedded in the received signal. VSYNC is detected based on the minimum pulse width defined by the DSS.RFBI_VSYNC_WIDTH register.

HSYNC is detected based on the minimum pulse width defined by the DSS.RFBI_HSYNC_WIDTH register.

The signal is generated from external logic based on the VSYNC/HSYNC of the LCD panel. The automatic trigger can be programmed based on the RFBI_TE signal or use a bit field in the RFBI registers to start data capture.

The polarity of the TE signal is programmable. The HSYNC and VSYNC pulses embedded in the TE signal have the same polarity, which is active high for an ORed signal and active low for an ANDed signal. The minimum pulse width of the signal is two L4 cycles. Hardware resets the line counter when the VSYNC occurs and increments it at every HSYNC. Transfer to the LCD panel begins when the line counter reaches the programmable line number.

13.3.2.1.1.2 Parallel Interface in Bypass Mode (MIPI DPI Protocol)

When bypass mode is enabled, the display controller must be set to use it.

Figure 13-5 shows the LCD support parallel interface in bypass mode.

Figure 13-5. LCD Support Parallel Interface (Bypass Mode)

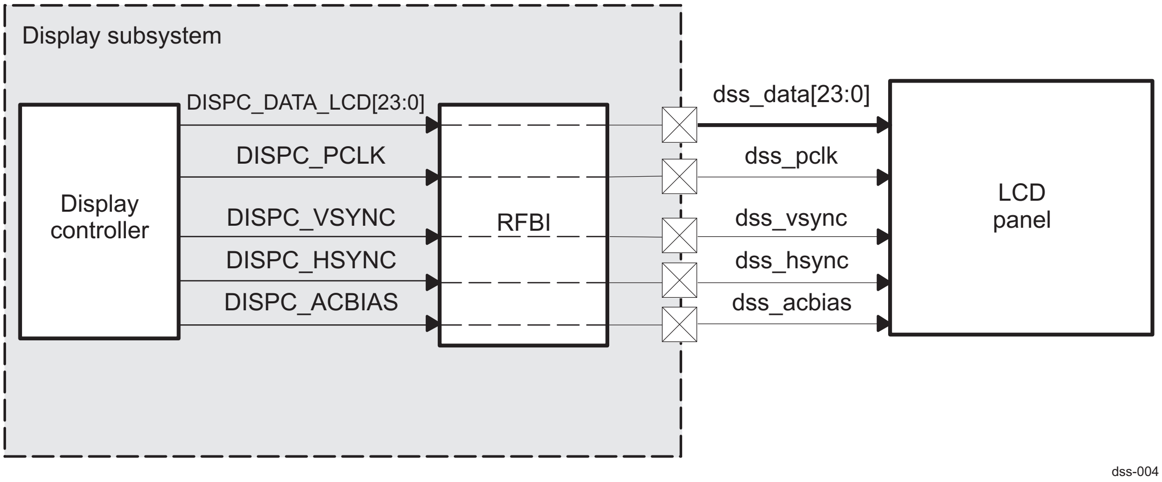


Table 13-8 describes the interface signals to/from the LCD panel in bypass mode.

Table 13-8. LCD Interface Signals (Bypass Mode)

Signal Name	Type[1]	Description
DISPC_DATA_LCD[23:0]	O	LCD data from the display controller module
DISPC_PCLK	O	Pixel CLK from the display controller module
DISPC_VSYNC	O	VSYNC from the display controller module
DISPC_HSYNC	O	HSYNC from the display controller module
DISPC_ACBIAS	O	ACBIAS from the display controller module

[1] I = Input, O = Output, I/O = Input/Output

- DISPC_DATA_LCD[23:0]: The panel pixel data comes directly from the display controller module. DISPC_DATA_LCD is connected at the chip-level boundary with dss_data[23:0].
- DISPC_PCLK: This signal is the pixel clock that comes directly from the display controller. This signal is multiplexed at the chip-level boundary with dss_pclk.
- DISPC_VSYNC: Uses the vertical synchronization signal from the display controller. The LCD frame clock (VSYNC) toggles after all the lines in a frame are transmitted to the LCD panel and a programmable number of line clock cycles has elapsed both at the beginning and at the end of each frame. This signal is multiplexed with dss_vsync at the chip-level boundary.
- DISPC_HSYNC: Uses the horizontal synchronization signal from the display controller. The LCD line clock (HSYNC) toggles after all pixels in a line are transmitted to the LCD panel and a programmable

number of pixel clock wait-states elapse, both at the beginning and at the end of each line. This signal is multiplexed on the chip-level boundary with dss_hsync.

- DISPC_ACBIAS: Uses the ac-bias signal from the display controller.
  - In passive matrix technology, the ac-bias signal is configured to transition each time a programmable number of line clocks occurs. To prevent a dc charge within the screen pixels, the power and ground supplies of the panel are periodically switched. The DISPC signals the panel to switch the polarity by toggling the ac-bias pin.
  - In active matrix technology, the ac-bias signal acts as an output-enable signal to indicate when data must be latched using the pixel clock. This signal is multiplexed on the chip-level boundary with dss_acbias.

13.3.2.1.1.3 LCD Output and Data Format for the Parallel Interface

This section describes the pixel data bus and shows timing diagrams of transactions and synchronizations in both RFBI and bypass modes.

Figure 13-6 through Figure 13-12 show the pixel data bus for bypass mode, depending on the use of 4-, 8-, 12-, 16-, 18-, or 24-pixel data output pins. In RFBI mode, the pixel data bus is reformatted in accordance with the input and output data bus width.

Table 13-9 lists the number of displayed pixels per pixel clock cycle based on the type of display panel.

Table 13-9. Number of Displayed Pixels per Pixel Clock Cycle Based on Display Type

Display Panel	Number of Displayed Pixels per Pixel Clock Cycle
Monochrome 4-bit	4
Monochrome 8-bit	8
Passive matrix color	8/3
Active matrix	1

- Passive matrix technology, Monochrome mode

  Monochrome displays use either a 4-bit or 8-bit interface. Each bit represents one pixel (on or off), which means that either 4 or 8 pixels are sent to the LCD at each pixel clock.

  Figure 13-6 and Figure 13-7 show 4- and 8-bit monochrome displays, respectively.

Figure 13-6. LCD Pixel Data Monochrome4 Passive Matrix

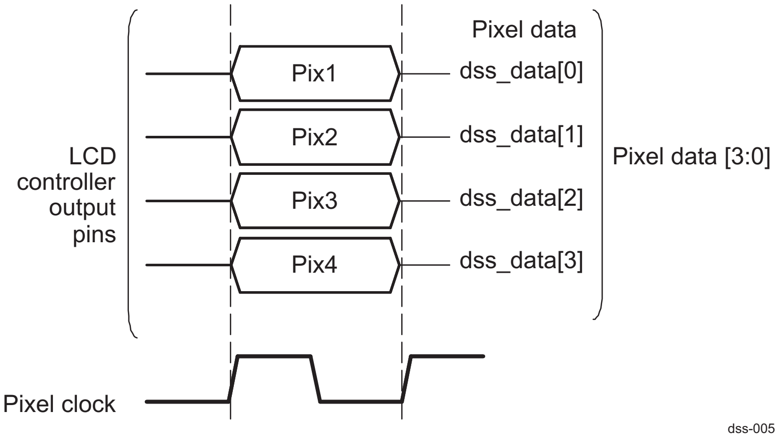

Figure 13-7. LCD Pixel Data Monochrome8 Passive Matrix

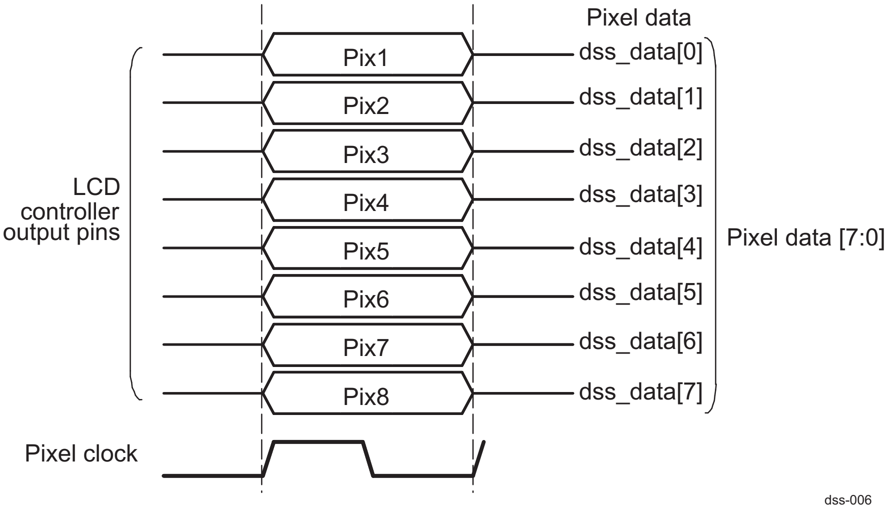


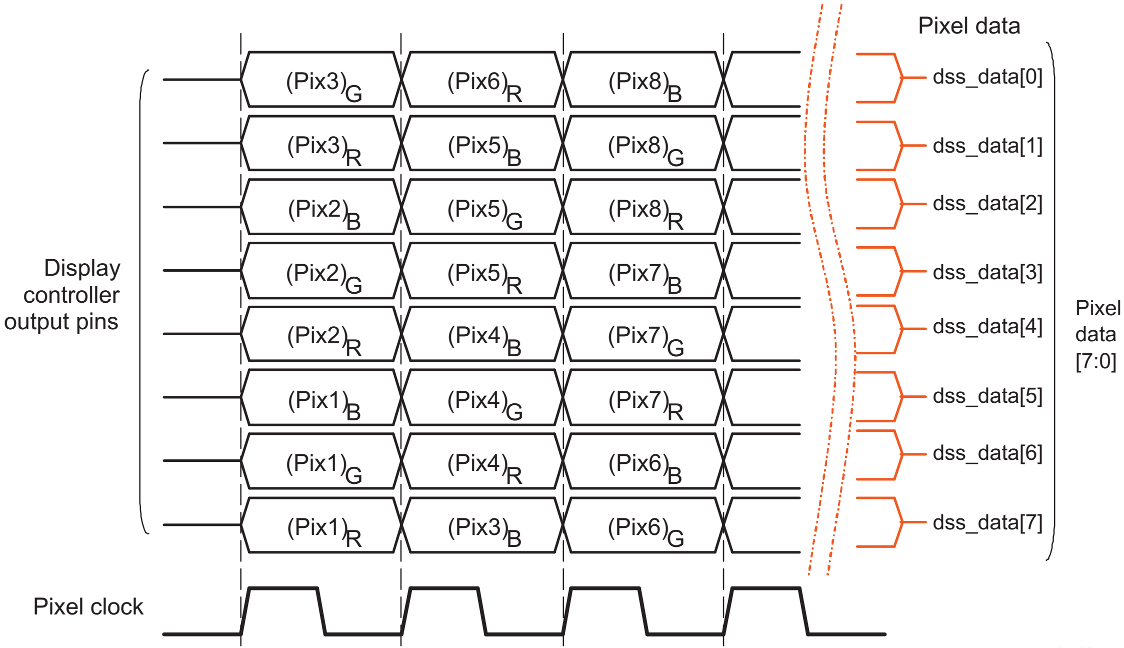
dss-006

- Passive matrix technology, color mode

  Color passive displays use 8-bit data input lines. In a given pixel clock cycle, each line represents one color component (red, green, or blue).

  Figure 13-8 shows an 8-bit color passive matrix display.

Figure 13-8. LCD Pixel Data Color Passive Matrix



dss-007

- Active matrix technology

  Active matrix displays bypass the STN dithering logic block and the output FIFO. Each line represents one pixel.

  Figure 13-9 through Figure 13-12 show 12-, 16-, 18-, and 24-active matrix displays, respectively.

Figure 13-9. LCD Pixel Data Color12 Active Matrix

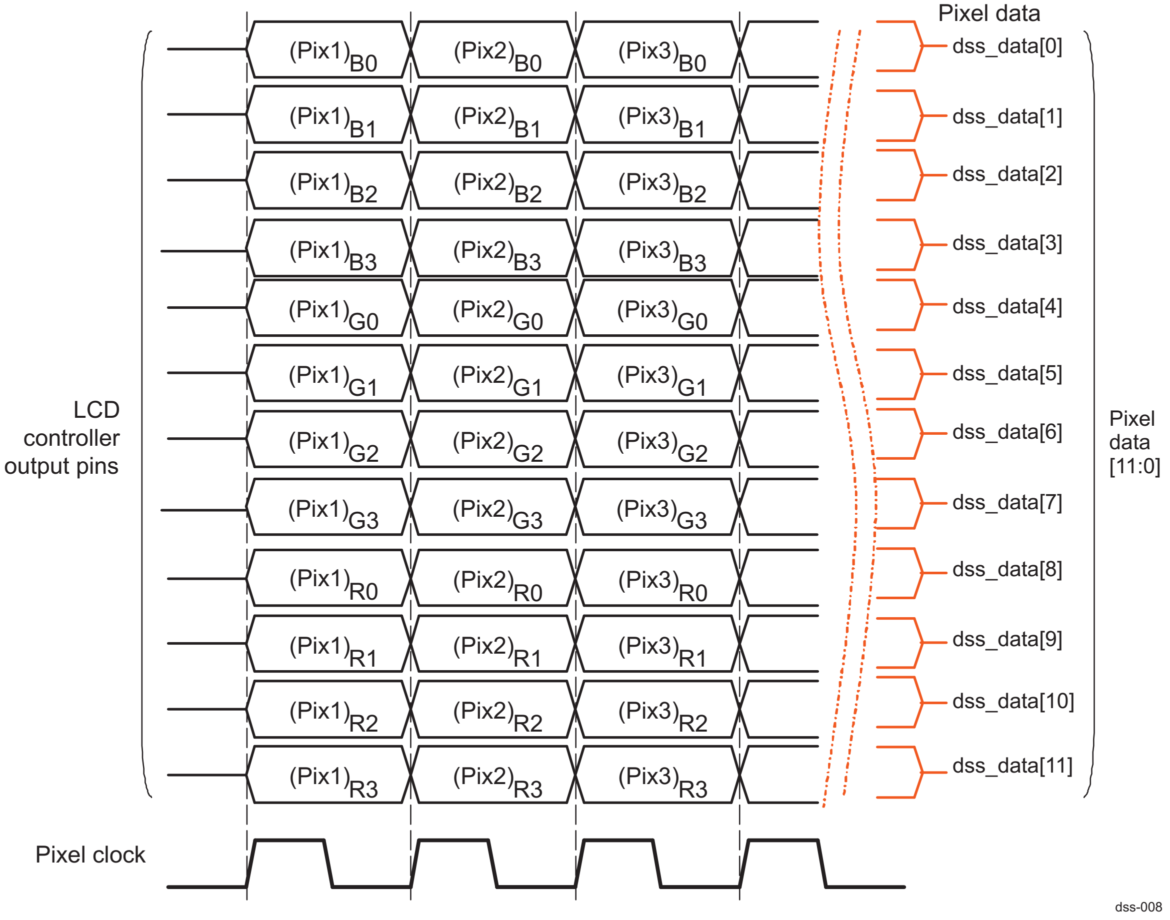


Figure 13-10. LCD Pixel Data Color16 Active Matrix

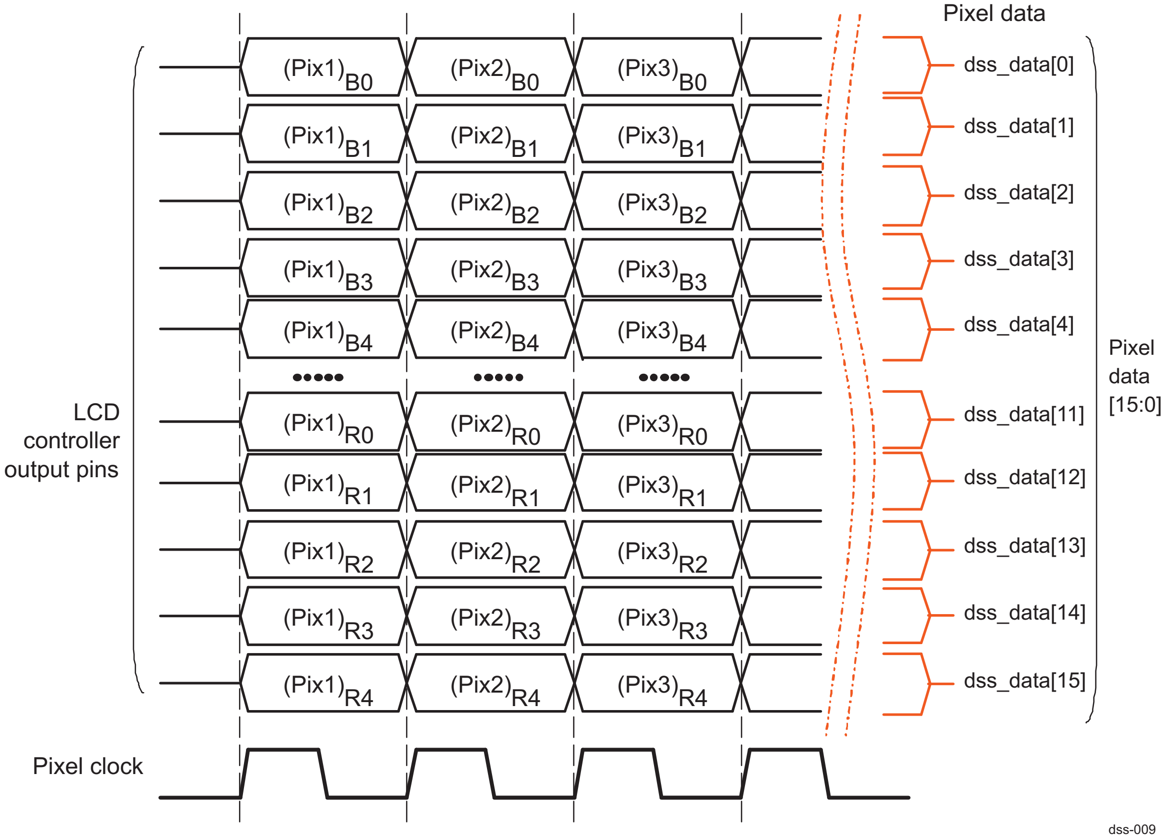

Figure 13-11. LCD Pixel Data Color18 Active Matrix

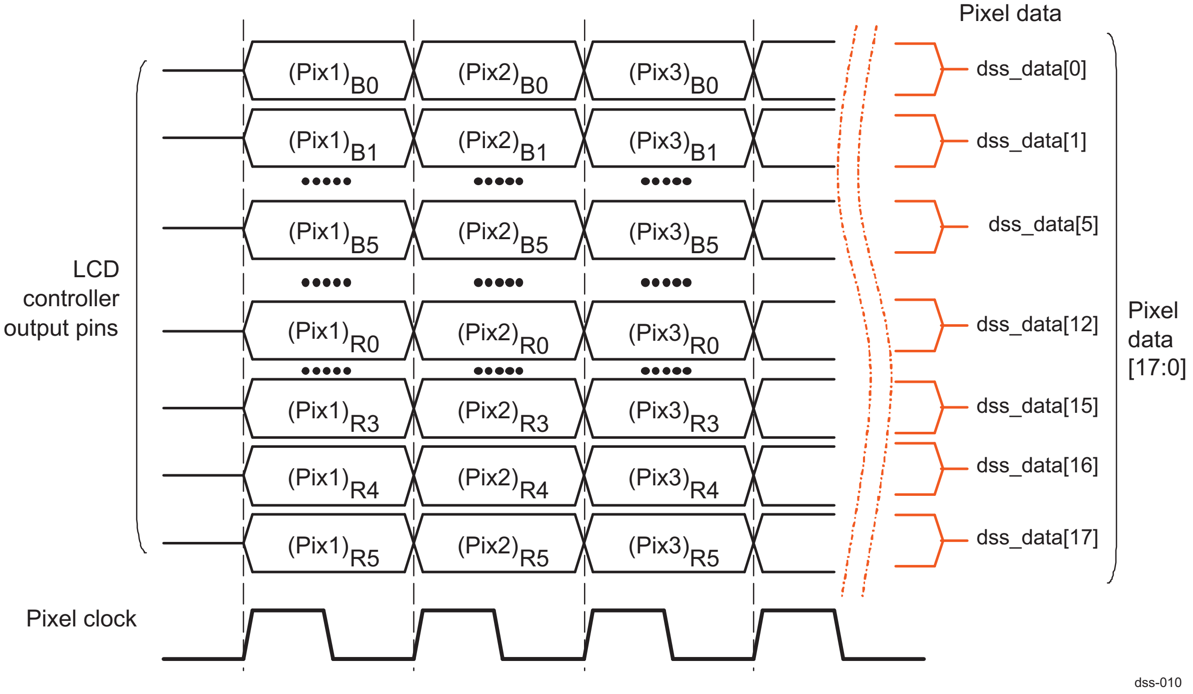

Figure 13-12. LCD Pixel Data Color24 Active Matrix

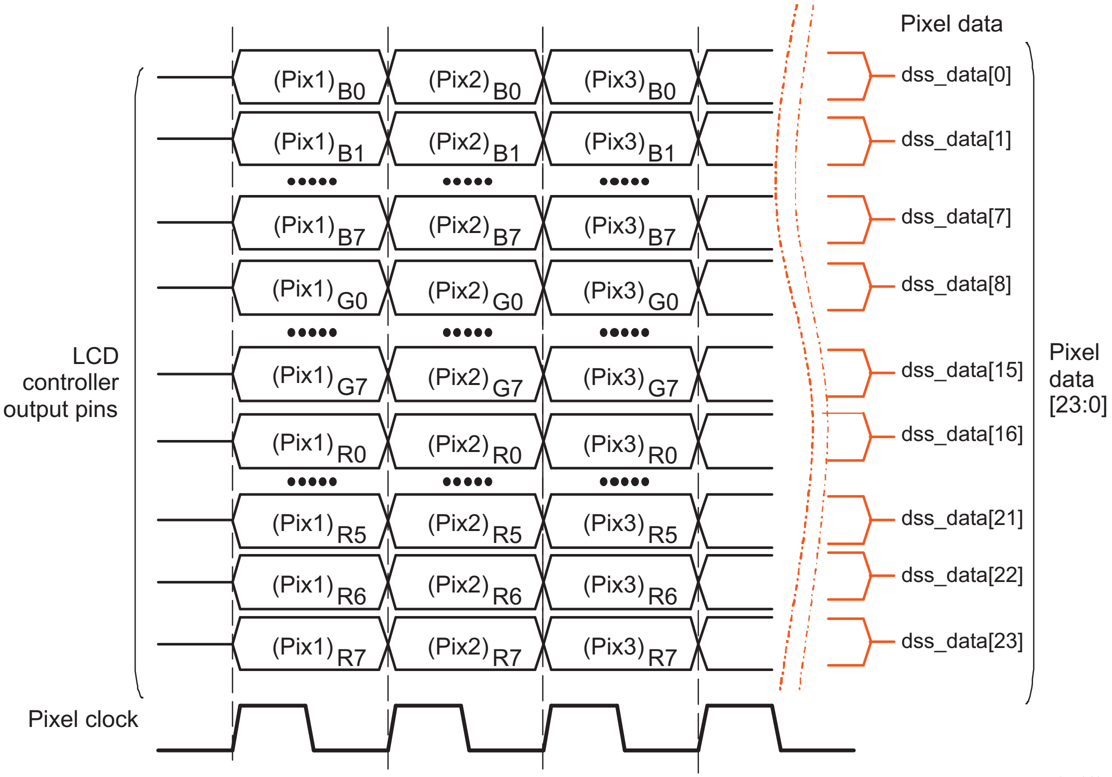
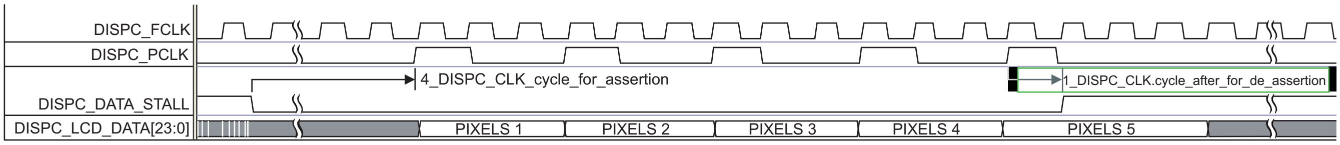


13.3.2.1.1.4 Transaction Timing Diagrams

- Timing diagrams in flow control mode
    - Stall signal

      The stall signal is used in RFBI mode. In the case of RFBI mode, it is used to indicate when the display controller must stop sending data over the LCD output interface. The RFBI module asserts the stall signal to stop data output by the display controller. It is deasserted to indicate when new data must be outputted by the display controller.

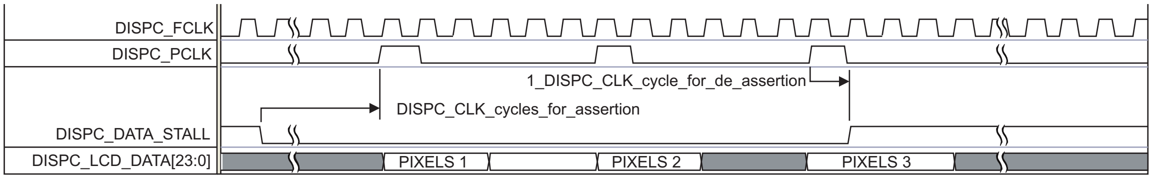
Figure 13-13. RFBI Data Stall Signal Diagram



To avoid underflow of the DMA FIFO, the FIFO handcheck feature can be enabled by setting the DSS.DISPC_CFG[16] FIFOHANDCHECK bit to 1. The fullness of the FIFOs associated with the pipelines used for the LCD output is checked when the STALL signal is inactive before providing data to the pipeline. This prevents emptying the FIFO when the RFBI module requests data and there is not enough data in the display controller DMA FIFO. This feature must be enabled only when the STALL mode is used (DSS.DISPC_CTRL[11] STALL_MODE bit set to 1).

When the FIFO handcheck feature is activated, the pixel transfer to the RFBI module during STALL inactivity period can be stopped (no DISPC_PCLK pulse) and restarted when there is enough data in the FIFO. The FIFO handcheck ensures that underflow cannot occur for the pipelines associated with the LCD output in RFBI mode. Figure 13-14 details the RFBI data stall with FIFO handcheck mode activated.

Figure 13-14. RFBI Data Stall Signal Diagram With Handcheck



- RFBI timing diagrams

Table 13-10 lists the programmable timing fields. Figure 13-15 through Figure 13-17 show timing diagrams of read/write transactions to the LCD panel for the RFBI mode.

Table 13-10. Programmable Timing Fields in RFBI Mode

Timing Name	Register Field	Description
CSOnTime	DSS.RFBI_ONOFF_TIMEi[3:0] CS_ONTIME (with I = 0 or 1)	CS assertion time from start access time
CSOffTime	DSS.RFBI_ONOFF_TIMEi[9:4] CS_OFFTIME (with I = 0 or 1)	CS deassertion time from start access time
WeCycleTime	DSS.RFBI_CYCLE_TIMEi[5:0] WE_CYCLE_TIME (with I = 0 or 1)	The time when A0 becomes valid until write cycle completion
WEOnTime	DSS_RFBI_ONOFF_TIMEi[13:10] WE_ONTIME (with I = 0 or 1)	WE assertion delay time from start access time
WEOffTime	DSS_RFBI_ONOFF_TIMEi[19:14] WE_OFFTIME (with I = 0 or 1)	WE deassertion delay time from start access time
RECycleTime	DSS.RFBI_CYCLE_TIMEi[11:6] RECYCLE_TIME (with I = 0 or 1)	The time when A0 becomes valid until read cycle completion
REOnTime	DSS_RFBI_ONOFF_TIMEi[23:20] RE_ONTIME (with I = 0 or 1)	RE assertion delay time from start access time
REOffTime	DSS.RFBI_ONOFF_TIMEi[29:24] RE_OFFTIME (with I = 0 or 1)	RE assertion delay time from start access time
CSPulseWidth	DSS.RFBI_CYCLE_TIMEi[17:12] CS_PULSE_WIDTH (with I = 0 or 1)	The time when write cycle time or read cycle time completes

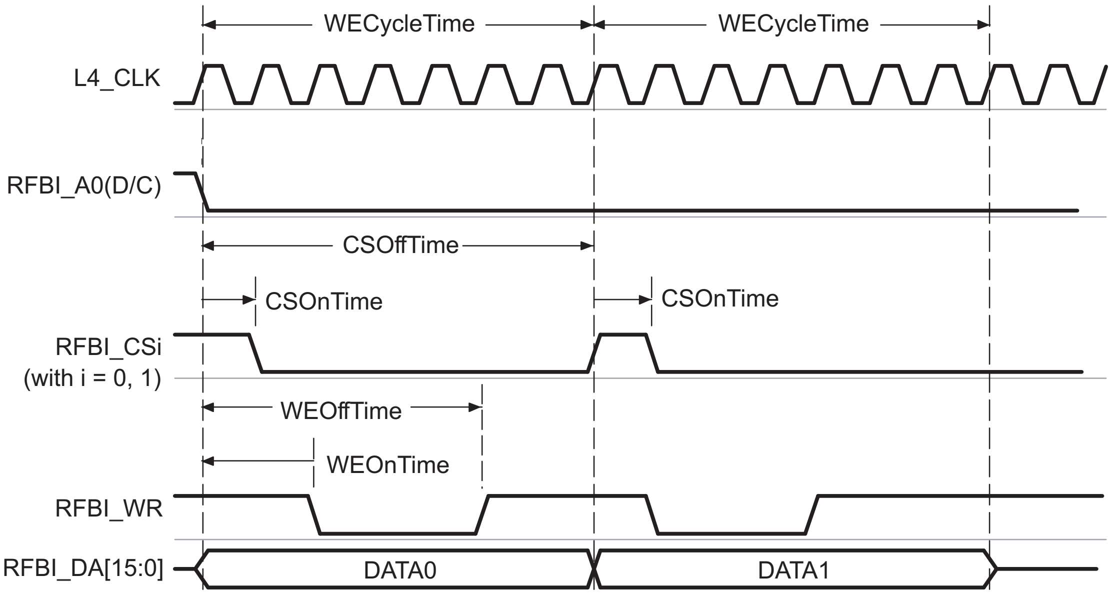

Figure 13-16. Display Data Read

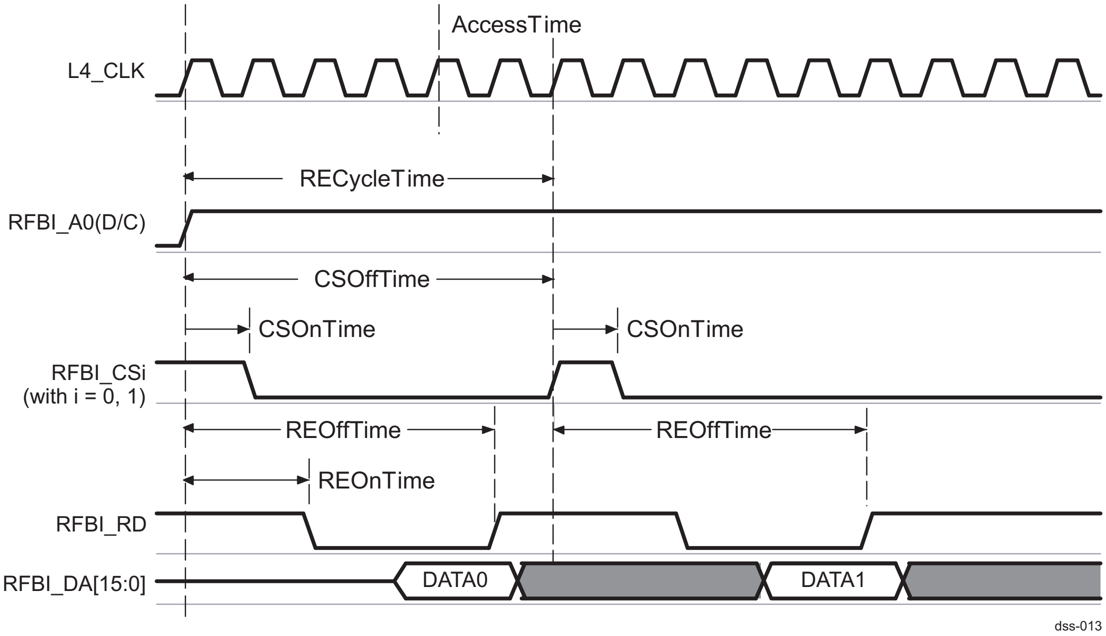

Figure 13-17. Read to Write and Write to Read

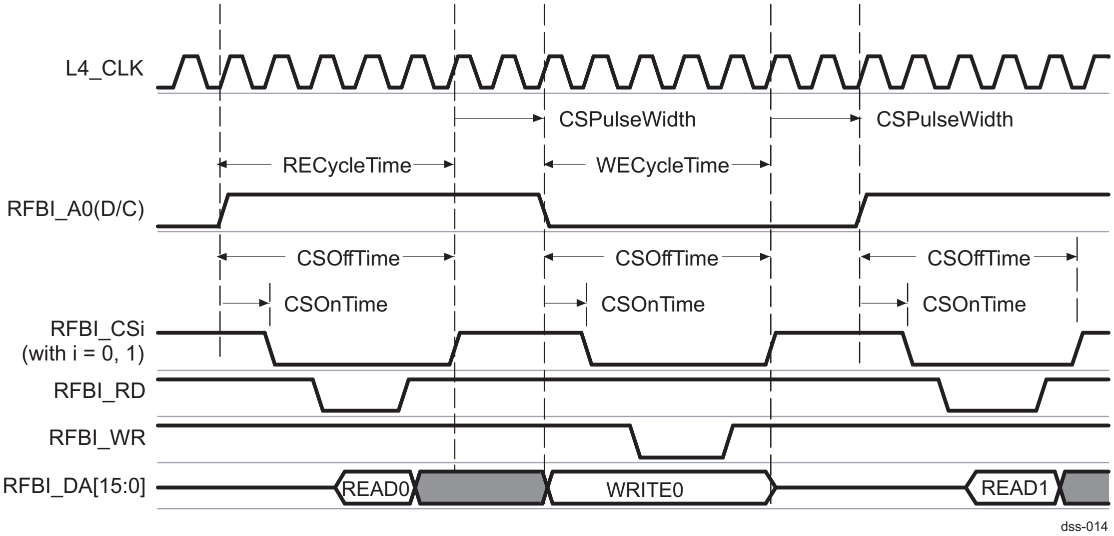

- Timing diagrams in bypass mode

  Figure 13-18 through Figure 13-33 show timing diagrams of synchronization signals and pixel clock in bypass mode for both passive matrix and active matrix panels. The display controller directly drives these signals, which are related to the programmable fields described in Table 13-11.

Table 13-11. Programmable Fields in Bypass Mode

Name	Register	Description
PPL	DSS.DISPC_SIZE_LCD[10:0] PPL bit field value + 1	Pixels per line (PPL)
LPP	DSS.DISPC_SIZE_LCD[26:16] LPP bit field value + 1	Lines per panel
HBP	DSS.DISPC_TIMING_H[31:20] HBP bit field value + 1	Horizontal back porch
HFP	DSS.DISPC_TIMING_H[19:8] HFP bit field value + 1	Horizontal front porch
HSW	DSS.DISPC_TIMING_H[7:0] HSW bit field value + 1	Horizontal synchronization pulse width

Table 13-11. Programmable Fields in Bypass Mode (continued)

Name	Register	Description
VBP	DSS.DISPC_TIMING_V[31:20] VBP bit field value	Vertical back porch
VFP	DSS.DISPC_TIMING_V[19:8] VFP bit field value	Vertical front porch
VSW	DSS.DISPC_TIMING_V[7:0] VSW bit field value + 1	Vertical synchronization pulse width
ONOFF	DSS.DISPC_POL_FREQ[17] ONOFF bit	DISPC_HSYNC and DISPC_VSYNC pixel clock control
RF	DSS.DISPC_POL_FREQ[16] RF bit	DISPC_HSYNC and DISPC_VSYNC pixel clock edge control
IEO	DSS.DISPC_POL_FREQ[15] IEO bit	Invert DISPC_ACBIAS
IPC	DSS.DISPC_POL_FREQ[14] IPC bit	Invert DISPC_PCLK
IHS	DSS.DISPC_POL_FREQ[13] IHS bit	Invert DISPC_HSYNC
IVS	DSS.DISPC_POL_FREQ[12] IVS bit	Invert DISPC_VSYNC

- Active matrix timing configuration 1
  - DSS.DISPC_POL_FREQ[17] ONOFF bit = 0
  - DSS.DISPC_POL_FREQ[16] RF bit = 0

    The DISPC_HSYNC and DISPC_VSYNC signals are driven on the opposite edge of DISPC_PCLK from the pixel data.
  - DSS.DISPC_POL_FREQ[15] IEO = 0

    The DISPC_ACBIAS signal is active high.
  - DSS.DISPC_POL_FREQ[14] IPC = 0

    The pixel data are driven on the rising edge of DISPC_PCLK.
  - DSS.DISPC_POL_FREQ[13] IHS = 0

    The DISPC_HSYNC signal is active high.
  - DSS.DISPC_POL_FREQ[12] IVS = 0

    The DISPC_VSYNC signal is active high.

- Active matrix timing configuration 2
  - DSS.DISPC_POL_FREQ[17] ONOFF bit = 1
  - DSS.DISPC_POL_FREQ[16] RF bit = 1

    The DISPC_HSYNC and DISPC_VSYNC signals are driven on the rising edge of DISPC_PCLK.
  - DSS.DISPC_POL_FREQ[15] IEO = 1

    The DISPC_ACBIAS signal is active low.
  - DSS.DISPC_POL_FREQ[14] IPC = 1

    The pixel data is driven on the falling edge of DISPC_PCLK.
  - DSS.DISPC_POL_FREQ[13] IHS = 1

    The DISPC_HSYNC signal is active low.
  - DSS.DISPC_POL_FREQ[12] IVS = 1

    The DISPC_VSYNC signal is active low.

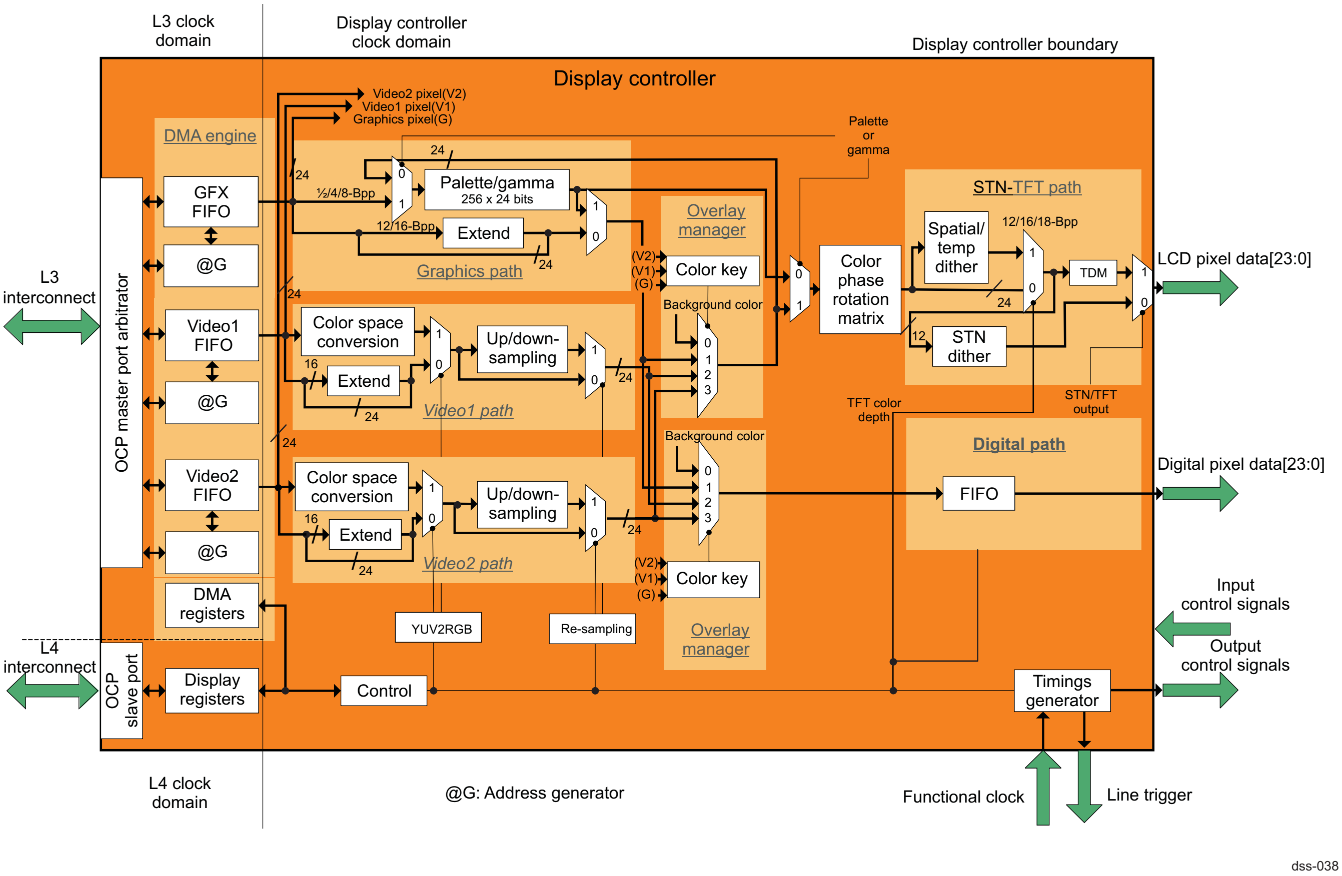
13.3.3 Display Controller Functionalities

The display controller can read and display the encoded pixel data stored in memory (see Figure 13-34).

Figure 13-34. Display Controller Architecture Overview



Several processes can be configured to manage the graphics pipeline (palette, gamma table correction) and video pipeline (color space conversion, upsampling, downsampling, overlay, and transparency features).

The internal timing generator logic generates the LCD input signals. The external timing generator generates the appropriated signals to drive the digital output. The data from the two overlay managers are sent on the two concurrent 24-bit buses outside the display controller module. The memory accessed by the display controller is either the SDRAM memory or the SRAM memory.

13.3.3.1 Display Modes

13.3.3.1.1 LCD Output

The display subsystem supports two types of display technologies (both monochrome and color modes):

- Passive matrix displays
- Active matrix displays

The passive matrix display mode supports 3375 possible colors, allowing 16, 256, or 3375 colors to be displayed in each frame, depending on the color depth. The monochrome LCD has 15 grayscale levels available.

In active matrix display mode, the configuration of colors depends on the color depth:

- 24 BPP supports 16,777,216 colors.
- 18 BPP supports 262,144 colors.
- 16 BPP supports 65,536 colors.
- 12 BPP supports 4096 colors.

13.3.3.1.2 Digital Output

The digital output is always a 24-bit RGB value based on an external pixel request.

13.3.3.2 Graphics Pipeline

The graphics pipeline is connected to the graphics FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of one 256-entry palette and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the most-significant bits [MSBs] for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the graphics pipeline is the replication logic used for RGB pixels, then the second unit is the palette for concerned pixels.

13.3.3.2.1 Graphics Memory Format

The supported formats for the graphics layer are CLUT bitmaps (1-, 2-, 4-, and 8-BPP) and true color bitmaps in RGB formats (12-, 16-, and 24-BPP [packet and nonpacket RGB24]) and in ARGB or RGBA formats (ARGB 16-, and 32-BPP, and RGBA 32-BPP) as follows:

- BITMAP 1-BPP data memory organization (CLUT) (little endian)

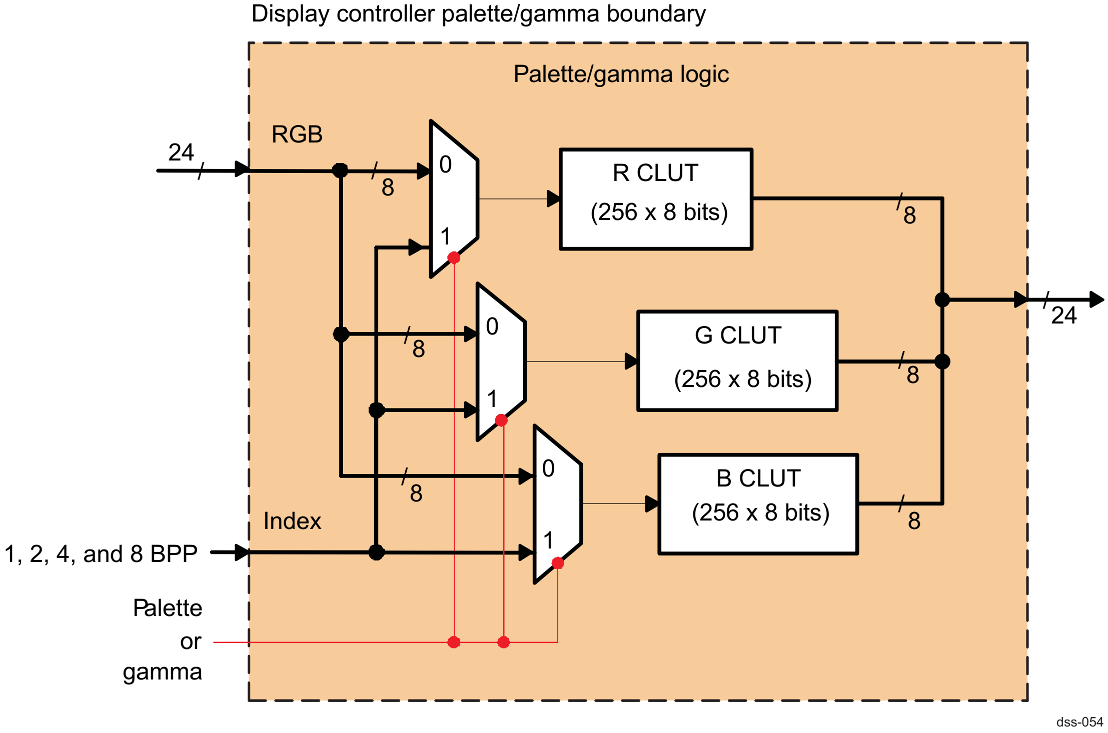
13.3.3.2.2 Color Look-Up Table/Gamma Table

The graphics path supports the palette/gamma table. Figure 13-35 shows the internal architecture of the color look-up/gamma table.

The palette is split into three memories of 256-bit x 8-bit entries. For bitmap (CLUT) indexes, the same value (1-, 2-, 4-, or 8-BPP) indexes the three memories. For gamma curve correction, each R, G, and B component indexes the corresponding memory to combine the three gamma curve values into a 24-bit value. The table can be reloaded every frame, once or never (at the beginning of the frame before fetching the pixels for the graphics and/or video windows).

Figure 13-35. Palette/Gamma Correction Architecture



13.3.3.2.2.1 *Color Look-Up Table*

The palette mode uses the encoded pixel values from the input graphics FIFO as pointers to index the 24-bit-wide palette: 1-BPP pixels address 2 palette entries, 2-BPP pixels address 4 palette entries, 4-BPP pixels address 16 palette entries, and 8-BPP pixels address 256 palette entries.

When a palette entry is selected by the encoded pixel value, the content of the entry is sent to the color/grayscale space/time base passive matrix dithering circuit, or to the color time base active matrix dithering circuit.

In color mode, the value within the palette is made up of three 8-bit fields, one for each color component (red, green, and blue). For color operation, an individual frame is limited to a selection of 256 colors (the number of palette entries). The format of one of the palette values in the memory is as follows:

- 24-BPP Data Memory Organization (Little Endian or Nibble)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused								R								G								B							

In monochrome mode, only one 8-bit value is present.

- 24-BPP Data Memory Organization (Little Endian or Nibble)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused								Unused								Unused								Gray							

After passing through the palette, 256 gray scales and 16,777,216 colors are numbers obtained. A redundancy introduced in the dithering logic step reduces these numbers when displaying. For passive matrix panels, the colors are limited to 15 gray scales and 3375 colors.

- Passive matrix technology

  The palette is bypassed in 12, 16, and 24 BPP. The palette is not used.
- Active matrix technology

The palette is bypassed in 12, 16, and 24 BPP, allowing up to 2^{24} = 16,777,216 colors to be displayed.

13.3.3.2.2.2 Gamma Table

In the gamma curve mode, the selected encoded pixel values based on the color keys from the video or graphics paths are sent to the gamma curve table. The mode is available only if the color look-up palette is not used for graphics. The output of the gamma curve processing is always sent to the LCD output. It is not available on digital output.

Each component of encoded pixel value is used as a pointer to index 1 out of 256 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to an R, G, or B component. The format of one of the gamma curve values in the memory is as follows:

- 24-BPP Data Memory Organization (Little or Big Endian)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused								Gamma-R								Gamma-G								Gamma-B							

13.3.3.2.2.2.1 Replication Logic

The replication logic increases the color depth of the graphics and video encoded pixels (from true color RGB 12-, and 16-BPP to 24-BPP). The encoded value is shifted to the 24-bit alignment. The MSB bits are copied to the LSB missing ones. Then the graphics are merged with the video data based on the transparency color keys. When the replication logic is not selected, the encoded pixel values are shifted to the MSB boundary of the 24-bit format. The missing bit values are filled up with 0s.

This is an example for RGB16 extension:

- Original 16-BPP data:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R4	R3	R2	R1	R0	G5	G4	G3	G2	G1	G0	B4	B3	B2	B1	B0

dss-T055

- If replication logic is ON:

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R4	R3	R2	R1	R0	R4	R3	R2	G5	G4	G3	G2	G1	G0	G5	G4	B4	B3	B2	B1	B0	B4	B3	B2

dss-T056

- If replication logic is OFF:

23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

dss-T057

13.3.3.3 Video Pipeline

The video pipeline is connected to the video FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of the Re-Sampling unit, the Color Space Conversion Unit, and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the MSBs for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the video pipeline is the Re-Sampling Unit, then the replication logic used for RGB pixels, then the Color Space Conversion Unit for YUV4:2:2 pixels.

13.3.3.3.1 Video Memory Formats

The display subsystem supports the following formats for the video layer: YUV2, UYVY, RGB12, RGB16, RGB24 (non-packed and packed formats), ARGB16 (video channel 2 only), ARGB32 (video channel 2 only), and RGBA32 (video channel 2 only).

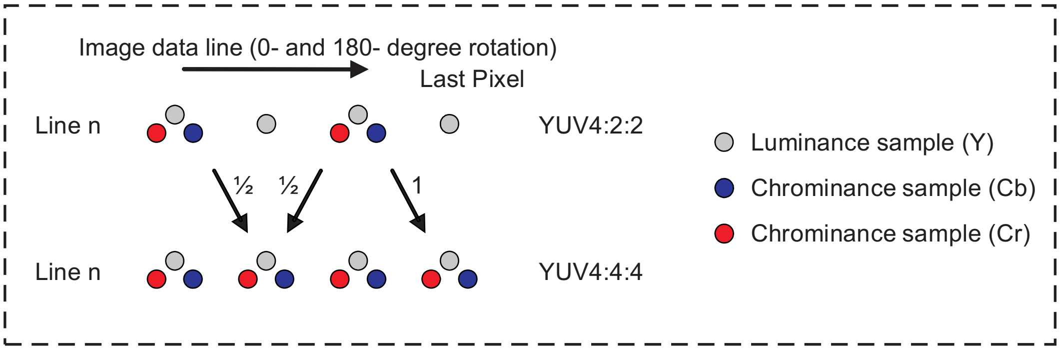
dss-T072

13.3.3.3.2 Color Space Conversion

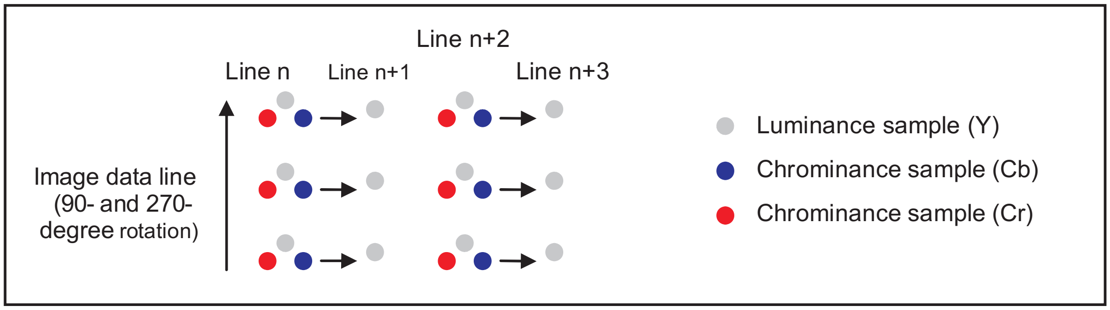
The color space conversion module converts the video-encoded pixel values from YCbCr 4:2:2 format into RGB24. Figure 13-36 and Figure 13-37 detail the YCbCr 4:2:2 conversion to YCbCr 4:4:4 depending on the rotation parameters.

Figure 13-36. YCbCr 4:2:2 to YCbCr 4:4:4 (0- or 180-Degree Rotation)



dss-061

Figure 13-37. YCbCr 4:2:2 to YCbCr 4:4:4 (90- or 270-Degree Rotation)



dss-060

The interpolation of the missing chrominance component is given by the equation in Figure 13-38.

Figure 13-38. Interpolation of the Missing Chrominance Component

$$Cb_n(YCbCr\ 444) = \frac{Cb_{n-1}(YCbCr\ 422) + Cb_{n+1}(YCbCr\ 422)}{2}\ (\text{n odd})$$

$$Cr_n(YCbCr\ 444) = \frac{Cr_{n-1}(YCbCr\ 422) + Cr_{n+1}(YCbCr\ 422)}{2}\ (\text{n odd})$$

dss-E062

First, to convert the YCbCr 4:2:2 encoded pixel values into YCbCr 4:4:4 format, the missing chrominance samples (Cb and Cr) are interpolated using the average values of the two closest values on the same line (1/2, 1/2) or are repeated from the second pixel in the same 32-bit container.

- In case of rotation 0-degree, for the last pixel, the chrominance samples are duplicated using the values from the previous pixel; otherwise, the chrominance samples are averaged using the two adjacent values.
- In case of 180-degree rotation, for the first pixel the chrominance samples missing are duplicated from

the adjacent pixel; otherwise, the chrominance samples are averaged using the two adjacent values.

- In case of rotation 90- and 270-degree, the missing chrominance components are duplicated from the adjacent pixel in the same 32-bit container.

In case of 5-tap configuration for the vertical filtering, the missing chrominance samples are always duplicated using the second chrominance samples in the same 32-bit value.

Then the pixels are converted from YCbCr color space into the RGB color space, because the output format of the color space conversion is RGB24 (8-bit value per component: Red, green, and blue). The following matrices show the 11-bit coefficients registers used to convert from YCbCr 4:4:4 into RGB24. Users set the coefficients according to the standard used to encode the pixel data in YCbCr color space.

In case of resampling, the YUV4:2:2 format is converted into YUV4:4:4. The YUV4:2:2-to-YUV4:4:4 processing is bypassed in the color space conversion unit.

If the active range for the luminance samples (Y) is [16:235] and [16:240] for the chrominance samples (Cb and Cr), the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in Figure 13-39 gives the 11-bit coefficients of the YCbCr to RGB color space conversion.

Figure 13-39. YCbCr to RGB Registers (VIDFULLRANGE = 0)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E063

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:255], the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in Figure 13-40 gives the 11-bit coefficients of the YCbCr-to-RGB color space conversion.

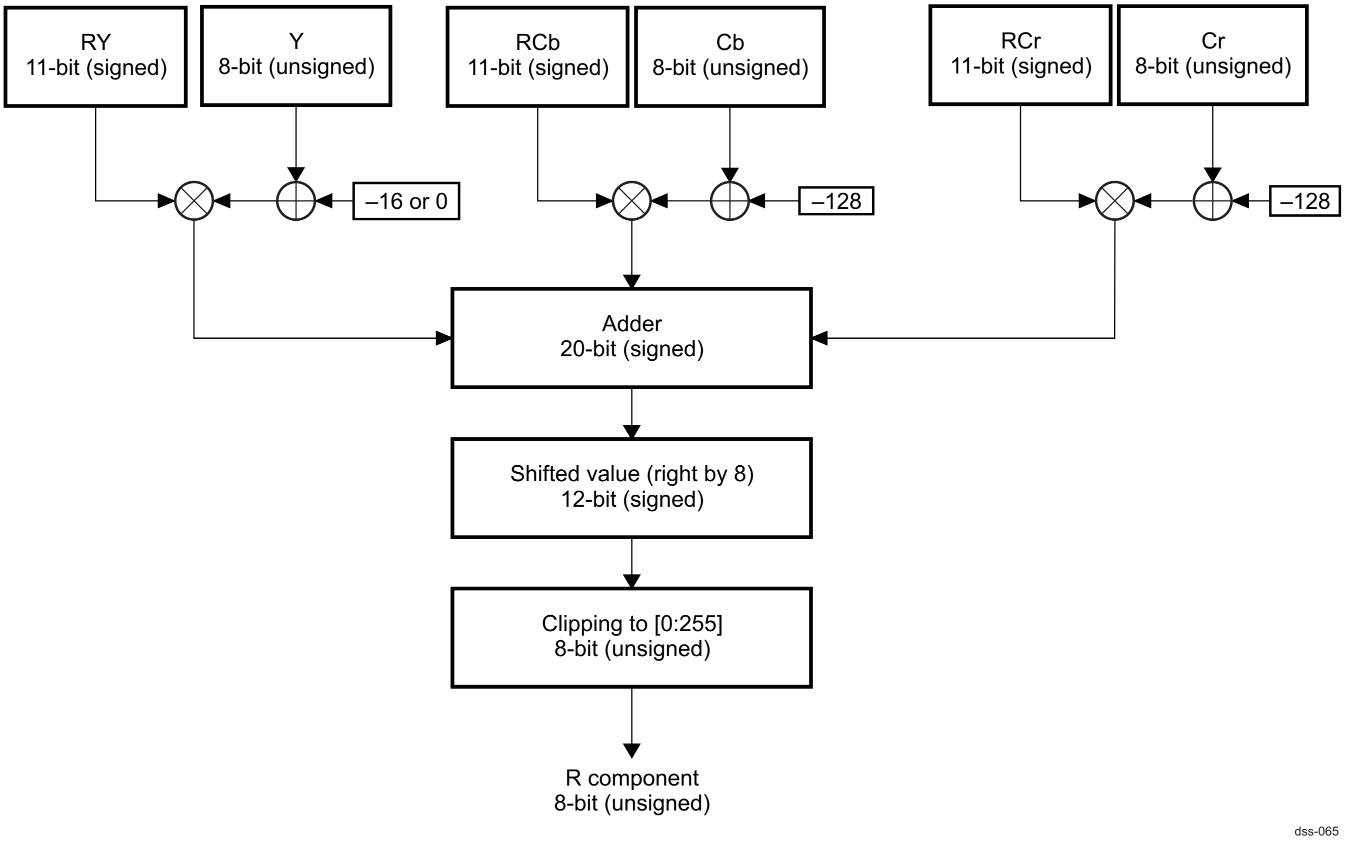
Figure 13-40. YCbCr to RGB Registers (VIDFULLRANGE = 1)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E064

Figure 13-41 describes the computation for the calculation of the R component. The same computation applies for the G and B components:

Figure 13-41. Color Space Conversion Macro-Architecture



13.3.3.3.3 Hardware Cursor

The video layer can be used to display the hardware cursor. The encoded pixel data for the cursor image are in RGB12, RGB16 or RGB24 formats and the color space conversion block is bypassed. The transparency color key can be used when a non rectangle shape is used.

The alpha blending can be used to show a partial transparent cursor. When the alpha blender is enabled, the graphics layer is on top of the video layers. The cursor uses the graphics layer. The pixel alpha blending or the transparency color key can be used.

13.3.3.3.4 Up-/Down-Sampling

The video layer has a dedicated resizing block to upsample and downsample the video-encoded pixels. The supported input formats from memory are RGB24, RGB16, and YUV4:2:2

(RGB12 and all the alpha formats like ARGB and RGBA are not supported)

Users must set the right size and position of the original video before resizing for the upsampled/downsampled video to be inside the display screen boundaries.

The filtering applies on each component independently R, G, and B).

For the horizontal up/downsampling, the equation is R component with five taps):

$$\mathrm{Rout}(n) = \left(\sum_{i=-2}^{i=2} \mathrm{Ci}(\Phi) \times \mathrm{Rin}(n+i) \right) >> 7 \qquad (5)$$

dss-E066

For the vertical up/downsampling, the equation is R component with three taps):

$$\mathrm{Rout}(n) = \left(\sum_{i=-1}^{i=1} \mathrm{Ci}(\Phi) \times \mathrm{Rin}(n+i) \right) >> 7 \tag{6}$$

dss-E067

For the vertical up/downsampling, the equation is R component with five taps):

$$\mathrm{Rout}(n) = \left(\sum_{i=-2}^{i=2} \mathrm{Ci}(\Phi) \times \mathrm{Rin}(n+i) \right) >> 7$$

dss-E068

Rout: R component output

$\mathrm{Ci}(\Phi)$ dss-E069 : FIR filter coefficients

Rin: R component input (7)

The pixel (n + 1) is older than pixel (n). The line (n + 1) is older than line (n).

NOTE: The coefficients Ci() depend on the phase between input and output pixels.

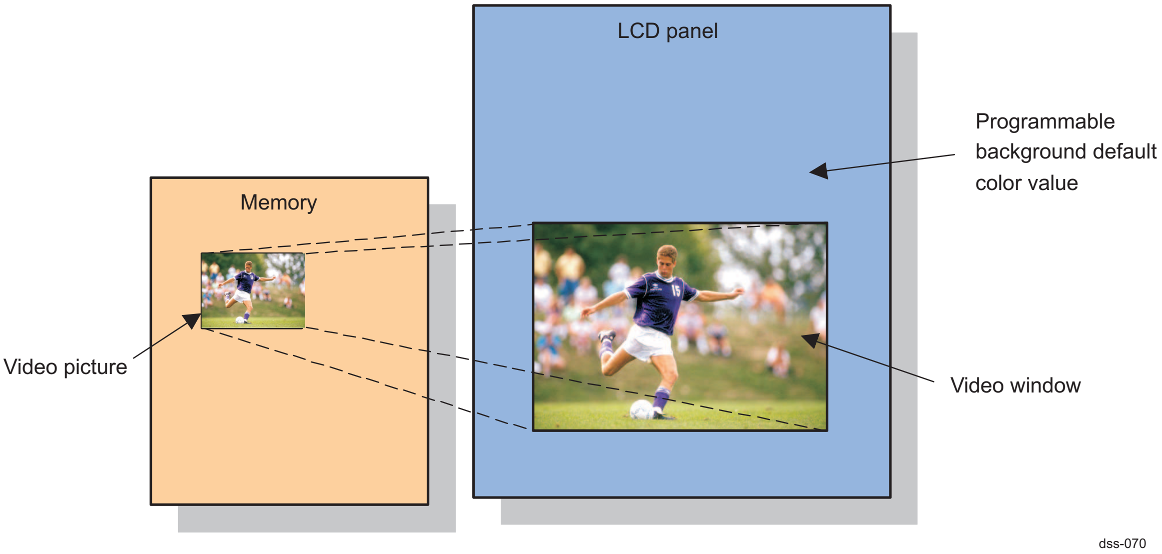
NOTE: If the 5-tap resizer is used for RGB16 and YUV4:2:2 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels:

DISPC_VIDn_ATTRS[21] VERTICAL_TAPS == 1

DISPC_VIDn_PICTURE_SIZE[10:0] VID_ORG_SIZE_X 4 and even

Figure 13-42 shows an example of video upsampling.

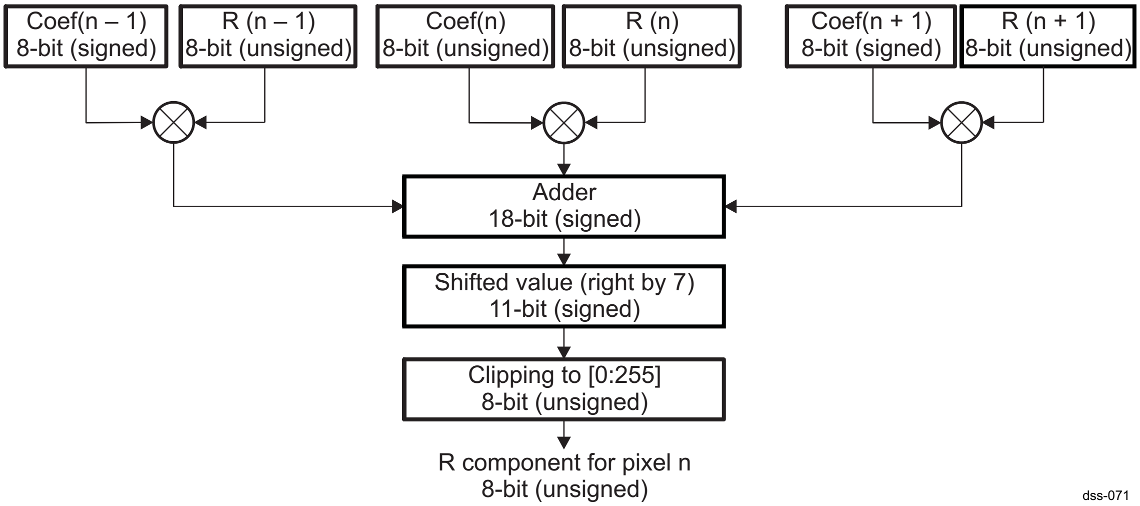
Figure 13-42. Video Upsampling



Filter Description

The up/downsampling filter is a poly-phase filter with five taps and eight phases for the horizontal filter and a programmable number of taps (three or five) and eight phases for vertical filter. The upsampling ratio is up to x8. The downsampling ratio using 3-tap configuration is/2. The downsampling ratio using 5-tap configuration is/4. The vertical filter is first applied to the encoded input pixel data; and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. Figure 13-43 shows the computation for the R component in the case of three coefficients (vertical filtering). The same computation applies to the G and B components.

Figure 13-43. Resampling Macro-Architecture (3-Coefficient Processing)



To determine if the minimum functional clock matches the down sampling ratio and the desired Pixel clock, the following formula must be used in conjunction with Table 13-12 and Table 13-13.

Ratio V when performing a vertical down-sampling only

$$h\_ratio = \frac{DISPC\_SIZE\_LCD.PPL}{DISPC\_VID\_SIZE.Vid\_Size\_X}$$

$$v\_ratio = \frac{DISPC\_VID\_PICTURE\_SIZE.Vid\_Org\_Size\_Y}{DISPC\_VID\_SIZE.Vid\_Size\_Y}$$

$$Ratio = \frac{v\_ration}{2 \times h\_ratio} \qquad If \quad 1 < v\_ratio \leq 2$$

$$Ratio = \max(\frac{v\_ration}{2 \times h\_ratio}, \frac{v\_ration - 2}{2 \times (h\_ratio - 1)}) \qquad If \quad 2 < v\_ratio \leq 4$$

dss_swpu108-E135

NOTE: For frequency ratio calculation on the TV output, it is correct to replace DISPC_SIZE_LCD with DISPC_SIZE_DIG.
When the down-sampling ratio is below 0.5, it is not possible to use a video in full screen.

Ratio H when performing a horizontal down-sampling only

$$Ratio = \frac{DISPC\_VID\_PICTURE\_SIZE.Vid\_Org\_Size\_X}{DISPC\_VID\_SIZE.Vid\_Size\_X}$$

dss_swpu108-E136

Ratio H+V when performing a horizontal and vertical down-sampling

Ratio = max (horizontal Ratio, vertical Ratio) as previously defined.

Table 13-12. Functional Clock Frequency Requirement in RGB16 YUV4:2:2—Active Matrix Display

Minimum Functional Clock (MHz)		Horizontal Resampling				
		Off	Up	1:1 – 1:2	1:2 – 1:3	1:3 – 1:4
Vertical Resampling	Off	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	Up	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	3-tap 1:1 to 1:2	2xPCLK	2xPCLK	4xPCLK	6xPCLK	8xPCLK
	5-tap 1:1 to 1:4	RatioxPCLK	RatioxPCLK	RatioxPCLK	RatioxPCLK	RatioxPCLK

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

Table 13-13. Functional Clock Frequency Requirement in RGB24—Active Matrix Display

Minimum Functional Clock (MHz)		Horizontal Resampling				
		Off	Up	1:1 – 1:2	1:2 – 1:3	1:3 – 1:4
Vertical Resampling	Off	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	Up	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	3-tap 1:1 to 1:2	2xPCLK	2xPCLK	4xPCLK	6xPCLK	8xPCLK
	5-tap 1:1 to 1:4	RatioxPCLK	RatioxPCLK	2xRatioxPCLK	2xRatioxPCLK	2xRatioxPCLK

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

Use case example:

An input picture of 1024*768 is scaled to an output picture of size of 800*600 and displayed onto a LCD of resolution1280*768 at a PCLK of 74.25 MHz with a DSS functional clock of 133 MHz.

In this example, a H+V down-sampling is done on the input picture. Firstly the Ratio V and H are determined and the resulting maximum value is taken to calculate the functional clock frequency required.

Ratio V: h_ratio = 1.6 and v_ratio = 1.28 then Ratio = 0.4

Ratio H: Ratio = 1.28

Ratio H+V: Ratio = max (1.28, 0.4) = 1.28

In this use case, the horizontal and vertical down sampling range are 1:1–1:2. The 3-tap or 5-tap configuration can be taken into consideration. Therefore, from Table 13-12 and Table 13-13, If in RGB16-YUV4:2:2:

- 3-taps → DSS functional clock = 4 * PCLK = 297 MHz
- 5-taps → DSS functional clock = Ratio * PCLK = 95.36 MHz

If in RGB24,

- 3-taps → DSS functional clock = 4 * PCLK = 297 MHz
- 5-taps → DSS functional clock = 2 * Ratio * PCLK = 190.72 MHz

In this use case, the pixel format supported is RGB16-YUV4:2:2 in a 5-tap configuration.

13.3.3.4 Overlay Support

CAUTION

Enabling overlay optimization (setting the DSS.DISPC_CTRL [12] OVLY_OPT bit) if no overlay region effectively exists (the DSS.DISPC_VIDn_ATTRS [0] EN bit is cleared, with n = 1, 2) leads to unpredictable behavior. The overlay optimization feature must be enabled only when an overlay area exists. Before enabling the overlay optimization, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFX_WINDOW_SKIP bit field must be first set according to the video1 and graphics windows overlap.

The overlay mechanism consists of displaying more than one layer (graphics and video layers) using rules based on priority and transparency color keys.

When the pixel format is ARGB or RGBA, the color key match logic uses only the RGB value defined by ARGB or RGBA. The alpha blending factor is ignored.

The overlay managers are based on the same rules for priority and transparency color keys (see Figure 13-46).

Each data pipeline is assigned a single overlay related to a single display controller output.

The overlay manager is connected to all three outputs of the pipelines (graphics, video1 and video2). The output of the LCD overlay manger is connected to the Spatial/Temporal Dithering, and Passive Matrix units and back to the palette unit in the case of Gamma correction.

13.3.3.4.1 Priority Rule

The overlay manager can be configured in two distinct modes:

- Alpha mode (only source color key with the graphics layer)
- Normal mode (no alpha support)

The following rules apply in normal mode:

The video1 layer is always on top of the graphics layer. The video2 layer is always on top of the video1 and graphics. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see Figure 13-48).

Figure 13-44. Overlay Manager in Normal Mode

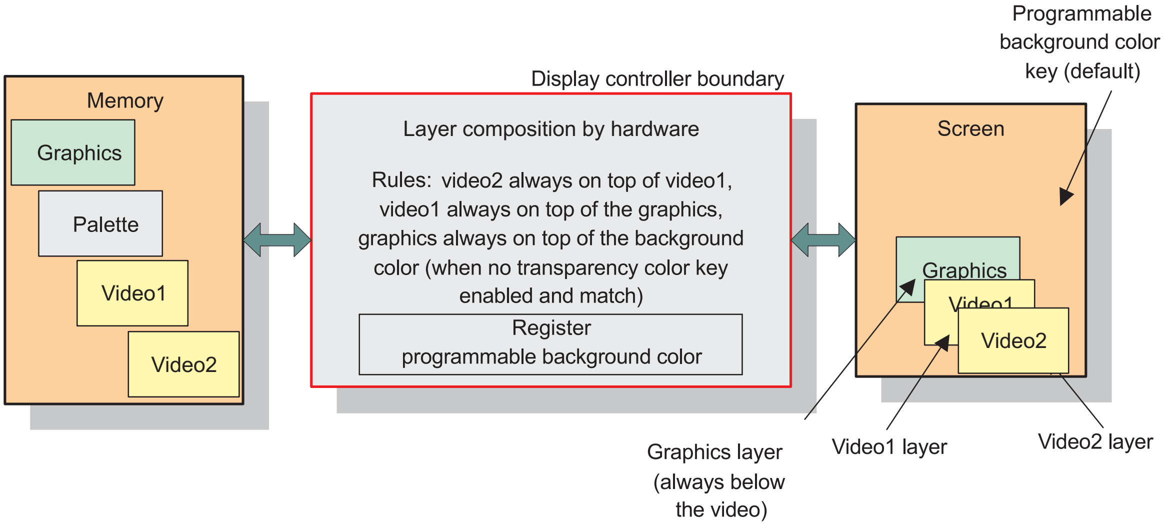


Figure 13-45. Display Attributes in Normal Mode

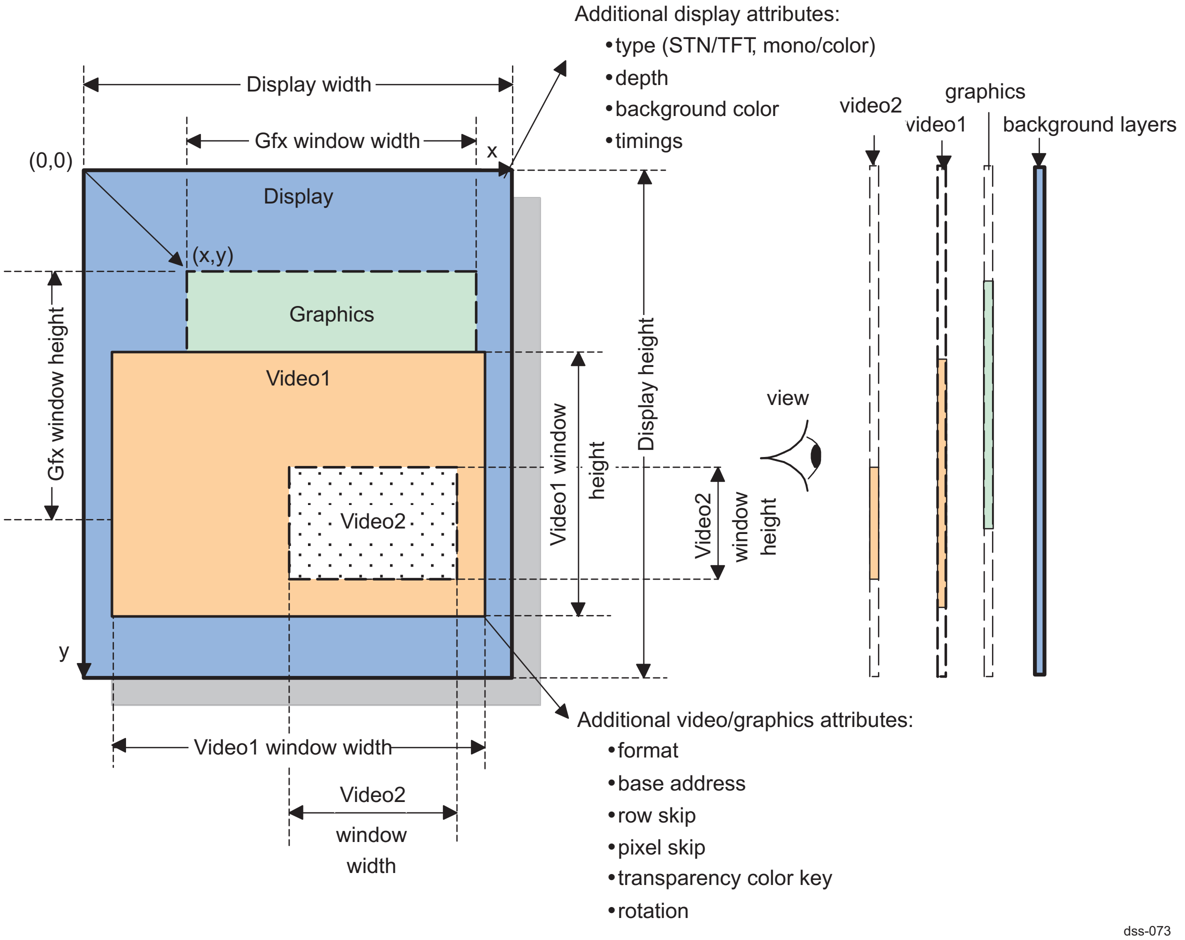

The following rules apply in alpha mode:

The video2 layer is always on top of the video1 layer. The graphics layer is always on top of the video1 and video2. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see Figure 13-48).

Figure 13-46. Overlay Manager in Alpha Mode

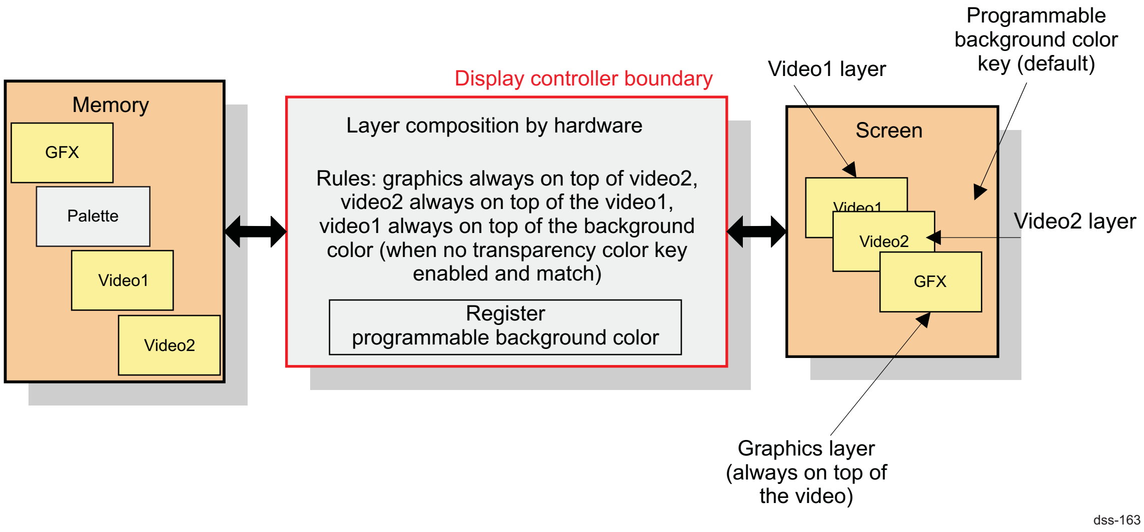

Figure 13-47. Display Attributes in Alpha Mode

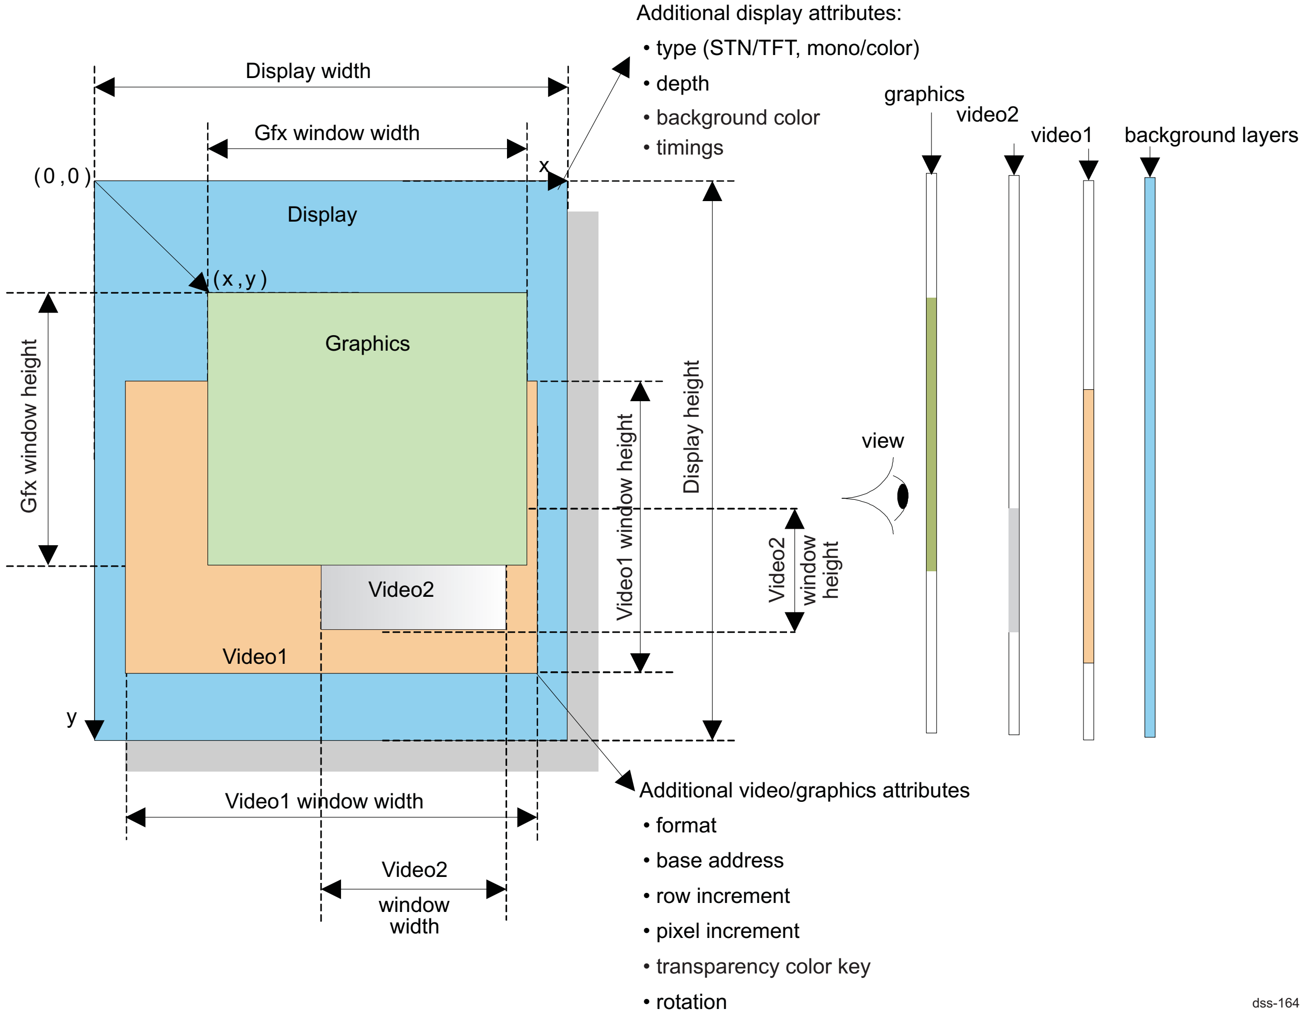

Figure 13-48 shows the alpha blending processing in detail.

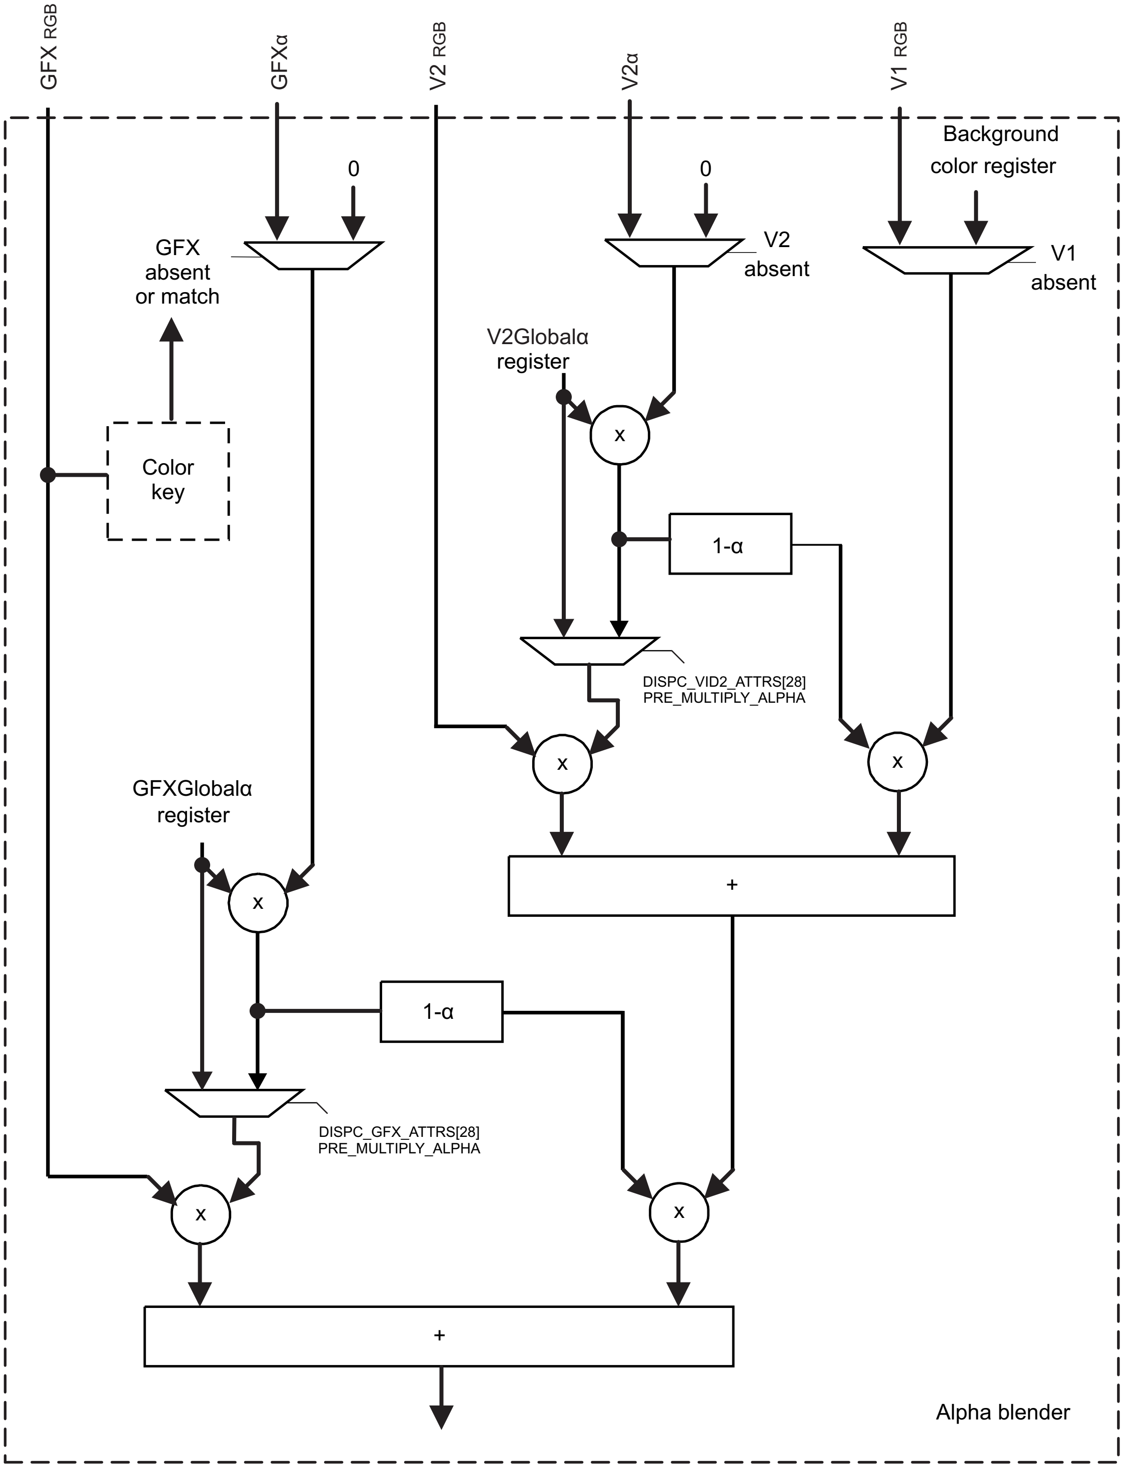
Figure 13-48. Alpha Blending Macro Architecture with Pre-multiplied Alpha Support



NOTE: "1-alpha" operator corresponds to the basic 1's complement operation.

The pre-multiplied alpha option is accessible through DSS.DISPC_GFX_ATTRS[28] PRE_MULTIPLY_ALPHA and DSS.DISPC_VIDn_ATTRS[28] PRE_MULTIPLY_ALPHA registers bits. The following settings are available:

- PRE_MULTIPLY_ALPHA bit = '0' : Source is not pre-multiplied with alpha. Full blending is done in the

DISPC.

- PRE_MULTIPLY_ALPHA bit = '1' : Source is pre-multiplied with alpha. Partial blending is done.

NOTE: The pre-multiplied alpha option is only valid when bit fields DSS.DISPC_GFX_ATTRS[4:1] GFX_FMT and DSS.DISPC_VIDn_ATTRS[4:1] VID_FMT, respectively, are set to ARGB or RGBA formats. Otherwise, the PRE_MULTIPLY_ALPHA bit fields are ignored by the hardware.

The alpha blending value is defined by the pixel value (ARGB or RGBA formats). A global alpha blending value can be defined and used in combination with the pixel alpha blending value. If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF.

In case of ARGB-444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value. Table 13-14 details the alpha blending 4-bit values and the corresponding blending percentage.

Table 13-14. Alpha Blending 4-Bit Values

Alpha Blending 4-Bit Value (ARGB-444)	Alpha Blending 8-Bit Value (Converted Value)	% Blending
0x0	0x00	100% (transparent)
0x1	0x11	93.33%
0x2	0x22	86.6%
...	...	...
0xE	0xEE	6.6%
0xF	0xFF	0% (opaque)

13.3.3.4.2 Transparency Color Keys

13.3.3.4.2.1 Normal Mode

This section describes the features available in normal mode.

The two transparency color keys are the video source transparency color key and the graphics destination transparency color key. The encoded pixel color value is compared to the transparency color key. For CLUT bitmaps, the palette index is compared to the transparency color key and not to the palette value pointed out by the palette index.

NOTE: The video source transparency color key and graphics destination transparency color key cannot be active at the same time.

- Video source transparency color key value:

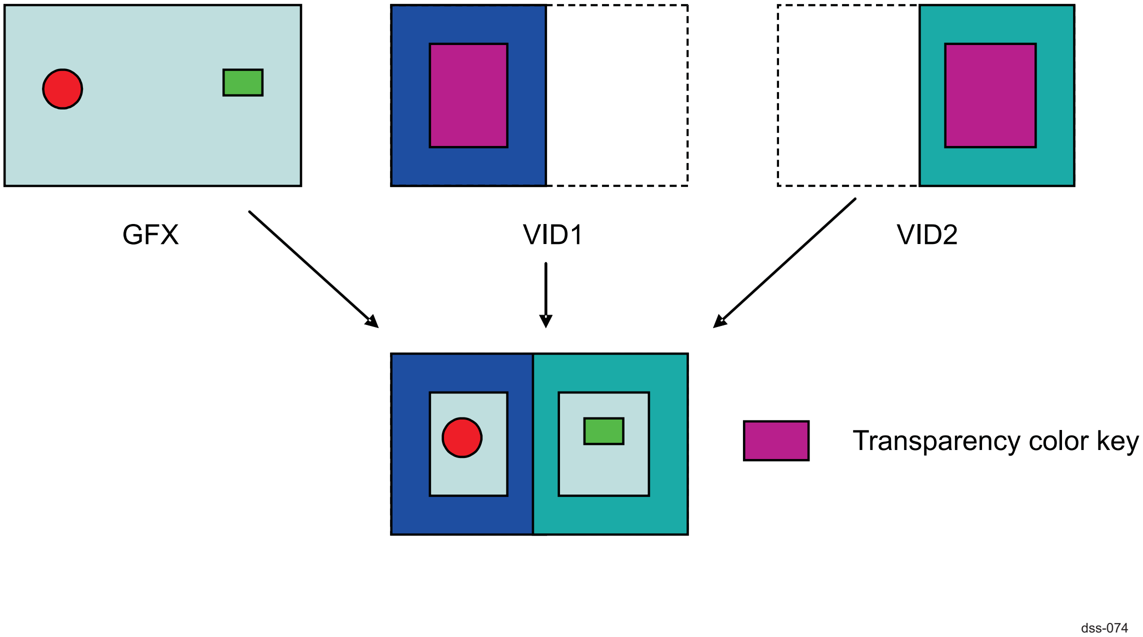
  The video source transparency color key value defines the encoded pixel data considered as the transparent pixel. The encoded pixel values with the source color key value are pixels not visible on the screen, and the underlayer encoded pixel values or solid background color are visible.

  The video source transparency color key can be used only if the color space conversion and the up/down-scaling modules are disabled. The format of the data is RGB 16. (This feature handles the hardware cursor displayed by one of the video layers.)

  To enable the video source transparency color key, set to 0x1 the DSS.DISPC_CFG[11] TCK_LCD_SELECTION bit for LCD output or the DSS.DISPC_CFG[13] TCK_DIG_SELECTION bit for digital output. Program the DSS.DISPC_CFG[10] TCK_LCD_EN bit (LCD output) or the DSS.DISPC_CFG[12] TCK_DIG_EN bit (digital output) to enable or disable the transparency color key.

  An example is shown in Figure 13-49: The video source transparency is applied on video1 (VID1) and video2 (VID2) layers. The pixels with the transparency color key are not displayed; instead, underlying layers are shown.

Figure 13-49. Video Source Transparency Example



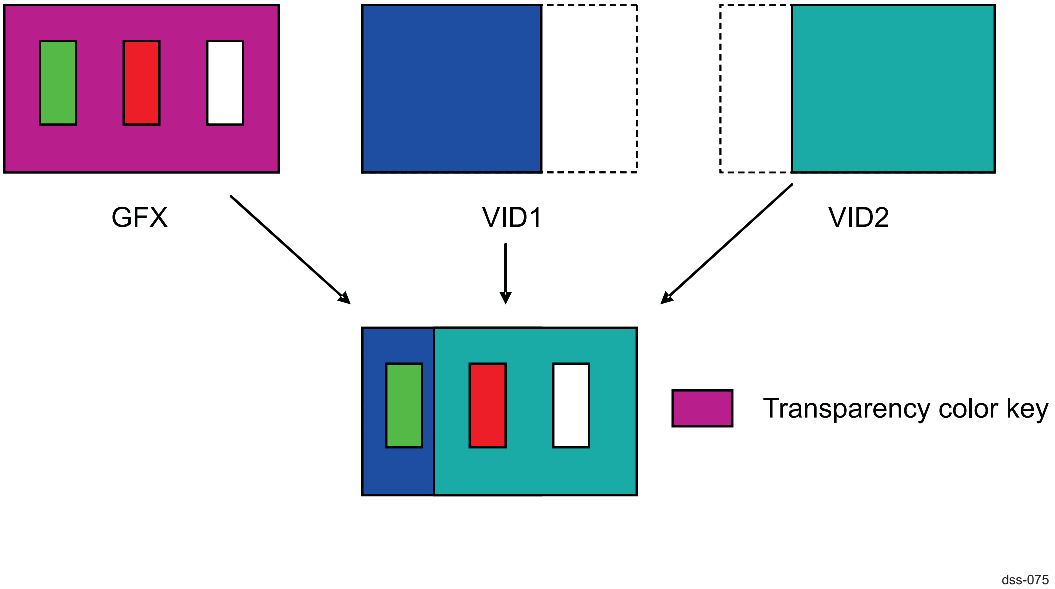
- Graphics destination transparency color key value:

  The graphics destination transparency color key value defines the encoded pixels in the video layers to be displayed. The encoded pixel values with the destination color key value are pixels not visible on the screen and the pixels different from the transparency color key are displayed over the video layers. The destination transparency color key is applicable only in the graphics region when graphics and video overlap; otherwise, the destination transparency color key is ignored.

  To enable the graphics destination transparency color key, set to 0x0 the DSS.DISPC_CFG[11] TCK_LCD_SELECTION bit for LCD output or the DSS.DISPC_CFG[13] TCK_DIG_SELECTION bit for digital output. Program the DSS.DISPC_CFG[10] TCK_LCD_EN bit (LCD output) or the DSS.DISPC_CFG[12] TCK_DIG_EN bit (digital output) to enable or disable the transparency color key.

  An example is shown in Figure 13-50: The destination transparency is applied on graphics (GFX) layer and the pixels without the transparency color key are displayed over the overlying layers.

Figure 13-50. Graphics Destination Transparency Example



13.3.3.4.2.2 Alpha Mode

This section describes the features available in alpha mode.

Only the graphics source transparency color key is available The encoded graphics pixel color value is compared to the transparency color key. The encoded pixel values with the source transparency key are not visible and the under-layer encoded pixel values or solid background color are visible. To enable the graphics source transparency color key, set to 0x0 the DSS.DISPC_CFG[11] TCK_LCD_SELECTION bit for LCD output or the DSS.DISPC_CFG[13] TCK_DIG_SELECTION bit for digital output. Program the DSS.DISPC_CFG[10] TCK_LCD_EN bit (LCD output) or the DSS.DISPC_CFG[12] TCK_DIG_EN bit (digital output) to enable or disable the transparency color key. In the case of CLUT bit maps, the palette index is compared to the transparency color key and not the palette value pointed out by the palette index.

13.3.3.4.3 Overlay Optimization (Only Available in Normal Mode)

The display controller can be configured to take advantage of the fact that the graphics pixels under video window 1 are not visible when the transparency color key is not used. The optimization can be selected to reduce the bandwidth used to fetch the pixels for graphics. The color key must be disabled. The graphics pixels under the video window 1 are not fetched from system memory. At least the video window 1 and the graphics window must be enabled. The following graphic formats are supported: RGB (RGB16 and RGB24 packed and unpacked), YUV4:2:2, and BITMAP 8. The formats BITMAP 1, 2, and 4 are not supported. The video format can be RGB (RGB16, RGB24 packed and unpacked, and YUV4:2:2 formats). The DMA engine does not fetch the unnecessary graphics pixels to avoid extra bandwidth use. Only visible pixels from graphics and video buffers in system memory are fetched and displayed by the display controller.

13.3.3.5 Active/Passive Matrix Display Data Path

For active matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation
- Spatial/temporal dithering
- Multiple cycle data format

For passive matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation
- Spatial/temporal dithering
- Passive matrix technology

13.3.3.5.1 Color Phase Rotation

The Color Phase Rotation (CPR) can be used to correct the LCD output colorimetry in case of non pure white backlight.

The color phase rotation can be selected for passive matrix and active matrix panel. The logic is integrated after the LCD overlay manager or the palette while using the gamma correction and before the spatial/temporal dithering. The color phase rotation can be selected to correct the nonpure white backlight of the LCD module by using a programmable matrix to convert the 24-bit RGB pixel value into a new 24-bit RGB pixel value. The matrix is programmed through a set of nine 10-bit signed coefficients. The output of the calculation is clipped to [0:255]. The color phase rotation is processed by the equation shown in Figure 13-51.

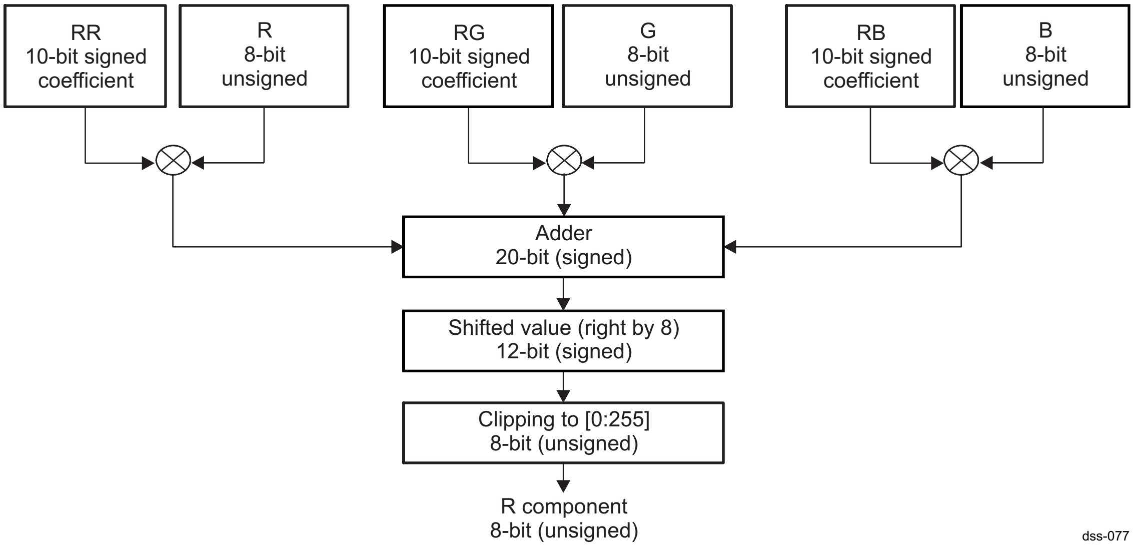
Figure 13-51. Color Phase Rotation Matrix

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \left(\begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix} \right)$$

dss-E076

Figure 13-52 shows the color phase rotation macro-architecture.

Figure 13-52. Color Phase Rotation Macro Architecture



13.3.3.5.1.1 Spatial/Temporal Dithering

The spatial/temporal dithering logic can be selected for passive matrix and active matrix panel. The dithering logic is integrated after the color phase rotation and before the TDM and passive matrix units. The spatial/temporal dithering logic can be selected to enhance the quality of the passive matrix and active matrix outputs. The dithering logic can process the pixels over a single frame, two frames, or four frames. In the case of a single frame, only spatial processing is applied. In the case of multiple frames, spatial and temporal processing is applied to the pixels.

- Passive Matrix Technology: The passive matrix display dithering logic path is used. The spatial/temporal dithering logic can be selected. When selected, the pixels are preprocessed by the spatial/temporal dithering logic before the passive matrix display dithering logic. The output format of the spatial/temporal dithering logic is RGB 12-bit (not configurable).
- Active Matrix Technology: The encoded pixel values are used by spatial/temporal dithering logic to display the data in a lower color depth on the LCD panel. The spatial/temporal dithering algorithm is based on the (x,y) pixel position, the value of removed bits and the frame number. The picture quality is improved when enabling the spatial/temporal dithering logic. When spatial/temporal dithering is not enabled, the three MSBs of the pixel color components are output on the interface data bus if the interface data bus is smaller than the pixel format size. If the interface data bus is wider than the pixel format size, by programming the pixel components replication active/inactive, the MSB is replicated to the LSB of the interface data bus or the LSB is filled with 0s.

13.3.3.5.2 Passive Matrix Display Dithering Logic

- Passive matrix technology

  After the graphics data are merged with the video data from the video layers depending on the transparency status, the result is sent to the color/grayscale space-/time-based dither generator. The monochrome data and each RGB color component are encoded on 4 bits, which are the 4 MSBs of the pixel-encoded component 8-bit value defined by the merge of the graphics data and the video data.

  These 4-bit values are used to select on the 16 intensity levels. The gray/color intensity is controlled by turning individual pixels on and off at varying period rates, making the average time the pixel is off longer than the average time the pixel is on, thus producing more intense grays/colors. The dithering generator also uses the intensity of adjacent pixels in the calculation to give the screen image a smooth appearance. The proprietary dither algorithm is optimized to provide a range of intensity values that matches the visual perception of color/gray graduations.
- Active matrix technology

The passive matrix dithering logic is always bypassed in active displays.

NOTE: If the interface data bus is smaller than the pixel format size, dithering logic can be enabled. If the interface data bus is wider than the pixel format size, the dithering logic cannot be enabled and replication feature can be used.

13.3.3.5.3 Passive Matrix Display Output FIFO

- Passive matrix technology

  The display controller contains a 2-entry by 8-bit-wide output FIFO used to store pixel data before it is driven out to the LCD pins. Each time a modulated pixel value is output from the dither generator, it is placed into a serial shifter. The shifter can be configured to be 4 or 8 bits wide. Single-panel monochrome screens use either four or eight data lines; single-panel color screens use eight data pins.
- Active matrix technology

  The output FIFO is bypassed in active matrix mode.

13.3.3.5.4 Multiple Cycle Output Format

The pixels after the active matrix display processing are formatted on one or multiple cycles (from one to three cycles). The interface width can be 8-, 9-, 12-, or 16-bit. On three cycles, two pixels can concatenate and send to the panel. When the TDM is disabled, the display controller outputs the pixels using the conventional formats: Passive matrix display/active matrix display monochrome/color.

The following example shows an output configuration based on the interface width (8-bit) and the pixel format output (24-bit) (also see Table 13-15):

- The DSS.DISPC_CTRL[24:23] TDM_CYCLE_FMT bit field is set to 0x2 (three cycles for one pixel).
- The DSS.DISPC_DATA_CYCLEk (k=0) register is set to 0x00000008 (8 bits from pixel 1 for the first cycle).
- The DSS.DISPC_DATA_CYCLEk (k=1) register is set to 0x00000008 (8 bits from pixel 1 for the second cycle).
- The DSS.DISPC_DATA_CYCLEk (k=2) register is set to 0x00000008 (8 bits from pixel 1 for the third cycle).

Table 13-15. 8-Bit Interface Configuration/24-Bit Mode

	24-Bit Mode		
	1st Cycle	**2nd Cycle**	**3rd Cycle**
Data[7]	R0[7]	G0[7]	B0[7]
Data[6]	R0[6]	G0[6]	B0[6]
Data[5]	R0[5]	G0[5]	B0[5]
Data[4]	R0[4]	G0[4]	B0[4]
Data[3]	R0[3]	G0[3]	B0[3]
Data[2]	R0[2]	G0[2]	B0[2]
Data[1]	R0[1]	G0[1]	B0[1]
Data[0]	R0[0]	G0[0]	B0[0]

13.3.3.6 Video Line Buffer

The line buffer size is 1024 x 24-bit. There are six line buffers (1024 x 24-bit) that can be merged into three lines (2048 x 24-bit). Table 13-16 lists the maximum width depending on the TAP configuration and the pixel format.

Table 13-16. Maximum Width Allowed

Vertical Tap	Pixel Format	Maximum Width (Pixels)
3	RGB16 RGB24 YUV4:2:2	2048
5	RGB16 RGB24 YUV4:2:2	1024

13.3.3.7 Synchronized Buffer Update

A synchronization mismatch between the frame buffer and the display refreshes, named tearing effect, can lead to images that appear to be stretched on the screen. To avoid this, a synchronization mechanism is needed between the display controller and the process that updates the buffer. An interrupt is generated when the display reaches a predefined line number. This PROGRAMMEDLINENUMBER interrupt is a level signal and stays active during the programmed line of the display.

13.3.3.8 Multiple Buffer Support

Users update the base address of the buffer when the update of the working buffer has finished and is ready to be displayed. The register that contains the base address of the buffer is a shadow register that is read by the hardware at the next Vertical Front Porch (VFP).

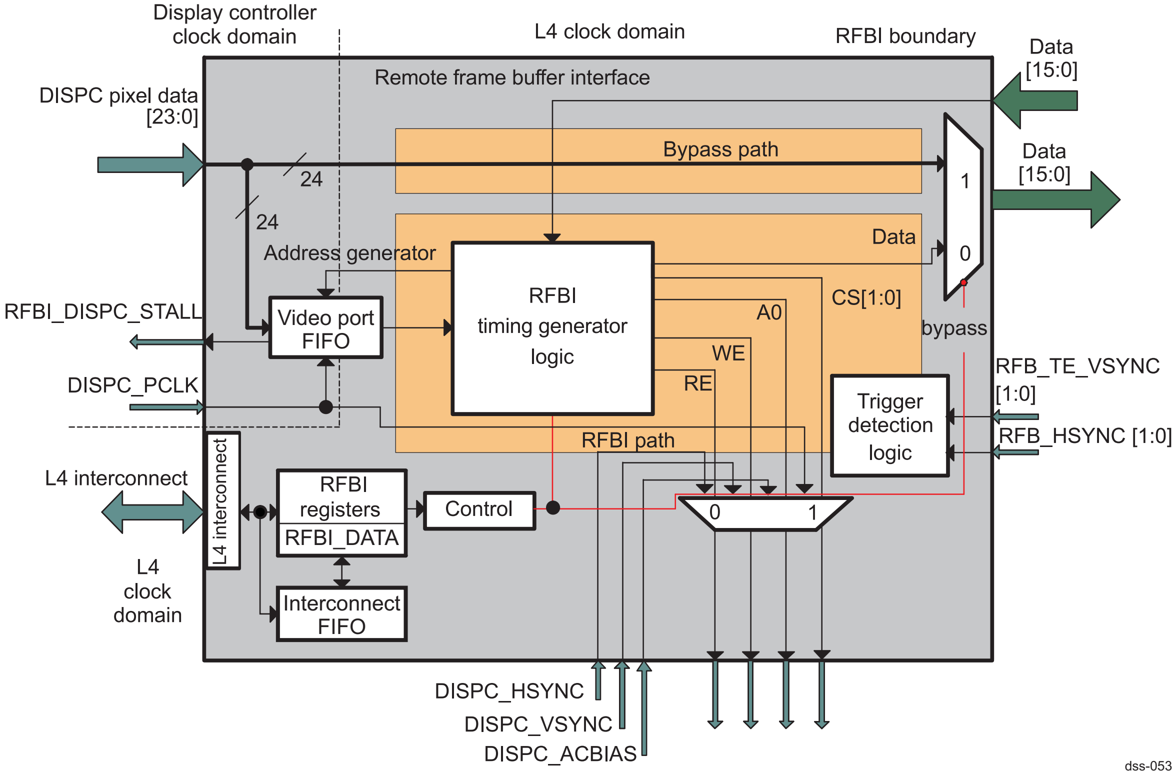
13.3.4 RFBI Functionalities

The RFBI module can capture the output pixel from the display controller and send the data to the RFB in the LCD panel. The application configures the RFBI module, sends commands, reads data, and configures the display controller to send data fetched from the system memory by the display controller DMA engine. The commands/data are sent using an 8-, 9-, 12-, or 16-bit parallel interface.

The display controller is configured to send the data in 12-, 16-, 18-, or 24-BPP format. In the video port FIFO, the encoded pixel values are in an LSB alignment independently of the endianness in system memory.

Figure 13-53 shows an overview of the RFBI architecture.

Figure 13-53. RFBI Architecture Overview



13.3.4.1 RFBI FIFO

The input video port FIFO receives data from the display controller at the pixel clock. The data in the video port FIFO are read by the RFBI and are sent to the LCD panel. The video port FIFO is 24 bits wide and each pixel in 12-, 16-, 18-, and 24-BPP format is stored in the video port FIFO using one 24-bit value aligned on the 24-bit LSB. Section 13.3.4.4, *Output Parallel Modes*, shows an example of an output configuration based on the interface width (16 bits) and the pixel format output (24 bits).

13.3.4.2 RFBI Interconnect FIFO

The interconnect FIFO receives the data from RFBI_DATA write requests to the L4 interconnect slave port. The data in the interconnect FIFO are read by the RFBI and sent to the LCD panel. The width of the interconnect FIFO is 32 bits. The size of the interconnect FIFO is 24 words of 32 bits (that is, 24 words of RFBI_DATA).

13.3.4.3 Input Pixel Formats

The supported pixel formats in the RFBI module are: RGB24-888, RGB18-666, RGB16-565, and RGB12-444 as output from the display controller and from the L4 (for writing parameters). In both cases, the pixels are formatted in accordance with the configuration of the output interfaces (multiple cycles).

13.3.4.4 Output Parallel Modes

The RFBI output modes are 8-, 9-, 12-, and 16-bit interfaces. Any mode can be selected regardless of the pixel format. Set the right configuration in the cycle registers to define a valid configuration for each output cycle.

The following example is an output configuration based on the 16-bit interface width and the 24-bit pixel format (i = 0 or 1) (see also Table 13-17):

- The DSS.RFBI_CONFIG_i[10:9] CYCLE_FMT bit field is set to 0x3 (three cycles for two pixels).

- The DSS.RFBI_DATA_CYCLE1_i register is set to 0x00000010 (16 bits from pixel 1 for the first cycle).
- The DSS.RFBI_DATA_CYCLE2_i register is set to 0x00080808 (8 bits from pixel 1 and pixel 2 and alignment of 8 bits from pixel 2 for the second cycle).
- The DSS.RFBI_DATA_CYCLE3_i register is set to 0x00100000 (16 bits from pixel 2 for the third cycle).

Table 13-17. 16-Bit Interface Configuration/24-Bit Mode

	24-Bit Mode		
	1st Cycle	**2nd Cycle**	**3rd Cycle**
Data[15]	R0[7]	B0[7]	G1[7]
Data[14]	R0[6]	B0[6]	G1[6]
Data[13]	R0[5]	B0[5]	G1[5]
Data[12]	R0[4]	B0[4]	G1[4]
Data[11]	R0[3]	B0[3]	G1[3]
Data[10]	R0[2]	B0[2]	G1[2]
Data[9]	R0[1]	B0[1]	G1[1]
Data[8]	R0[0]	B0[0]	G1[0]
Data[7]	G0[7]	R1[7]	B1[7]
Data[6]	G0[6]	R1[6]	B1[6]
Data[5]	G0[5]	R1[5]	B1[5]
Data[4]	G0[4]	R1[4]	B1[4]
Data[3]	G0[3]	R1[3]	B1[3]
Data[2]	G0[2]	R1[2]	B1[2]
Data[1]	G0[1]	R1[1]	B1[1]
Data[0]	G0[0]	R1[0]	B1[0]

13.3.4.5 Unmodified Bits

In a cycle, if every bit in the interface does not have a pixel value, the status of the unused bits can be programmed to be 0, 1, or the previous value (I/O power consumption optimization).

13.3.4.6 Bypass Mode

In bypass mode, the RFBI path is bypassed and the display controller data and signals are sent directly to the output interface of the RFBI.

13.3.4.7 Send Commands

The commands are written through the L4 interconnect and into the DSS.RFBI_CMD register. After a command is sent, another one can be accepted by the module and set. If the processing of a command is not complete, the MPU access to change the command stalls.

13.3.4.8 Read/Write

Depending on the status of A0, WE, and RE, the commands and display/parameter data are written to the panel (handled by the state-machine for the commands/parameter data and stored in memory for the display data), or the display data/status values are read from the LCD panel (status and display data in the LCD panel memory). The polarity of A0 (RFBI_A0 signal), WE (RFBI_WR signal), RE (RFBI_RD signal), and CSx (RFBI_CSx signal, with x = 0, 1) is programmable.

Table 13-18 describes the read/write function.

Table 13-18. Read/Write Function Description

A0 (RFBI_A0)	WE (RFBI_WR)	RE (RFBI_RD)	Function Description
1	0	1	Display data write, parameter data write
1	1	0	Display data read
0	1	0	Status read
0	0	1	Command data write

A minimum of RFBI_Cs cycle time, as defined in Table 13-19, is required to keep the RFBI_CSx signal asserted between write transfers of multiple pixels.

Table 13-19 indicates the minimum cycle time for RFBI_CSx, depending on the source of pixels (display controller or L4 interconnect slave port) and the cycle format (1pixel/cycle, 1 pixel/2 cycles, 1 pixel/3 cycles, or 2 pixels/3 cycles).

Table 13-19. Minimum Cycle Time for CSx/WE Always Asserted

RFBI Performance	RFBI_CONFIG_i[10:9] CYCLE_FMT	RFBI_CONFIG_i[8:7] L4_FMT	Minimum Cycle Time (in Number of L4 Cycles)
L4 interconnect	1 pixel/cycle	1 pixel	5
	1 pixel/2 cycles	1 pixel	4
	1 pixel/3 cycles	1 pixel	4
	2 pixels/3 cycles	1 pixel	6
	1 pixel/cycle	2 pixels	4
	1 pixel/2 cycles	2 pixels	4
	1 pixel/3 cycles	2 pixels	4
	2 pixels/3 cycles	2 pixels	6
Display Controller	1 pixel/cycle	N/A	4
	1 pixel/2 cycles	N/A	3
	1 pixel/3 cycles	N/A	3
	2 pixels/3 cycles	N/A	6

13.3.5 Hardware Requests

13.3.5.1 Display Controller DMA Request (Line Trigger)

One DMA synchronization line (DSS_LINE_TRIGGER) is connected to the sDMA by the sDMA controller (S_DMA_5) input line. This DMA request is not a classical one but a synchronization signal from the display subsystem to the sDMA informing the sDMA that a programmable number of lines are output to the LCD, and that the system memory can be updated. This allows the sDMA channel to be synchronized with the display subsystem internal DMA controller. In other words, it allows to synchronize a memory to memory frame buffer update based on the scan line of the frame buffer in system memory (SDRAM or SRAM) by the display controller. The DSS_LINE_TRIGGER DMA request is generated at a programmable line number defined in DSS.DISPC_LINE_NUMBER[10:0] LINE_NUMBER bit field.

13.3.5.2 RFBI DMA Request

The RFBI_DMA_REQ is used to receive data into the RFBI FIFO. The DMA request is always generated when there is enough room in the FIFO to accept the full burst.

13.3.5.3 DISPC Interrupt Request

The interrupt line indicates when one or more events are detected by the hardware. Each event is independently maskable by setting the DSS.DISPC_IRQEN register.

To check when a particular interrupt event occurs and to reset a particular event, the DSS.DISPC_IRQSTS register must be accessed. This register regroups all the status of the module internal events that generate an interrupt (read 0: No interrupt occurred; read 1: Interrupt occurred; write 1: Status bit reset). See the registers in Section 13.6 for more information on checking and clearing interrupt events. Table 13-20 lists the display subsystem interrupt events.

Table 13-20. Display Subsystem Interrupts

Interrupt Name	Description
FRAMEDONE	Active frame is complete and LCD output is disabled.
VSYNC	VSYNC interrupt occurred at the end of the frame.
EVSYNC_EVEN(1)	EVSYNC_EVEN interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is even.)
EVSYNC_ODD(1)	EVSYNC_ODD interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is odd.)
ACBIASCOUNTSTATUS	The ac-bias transition counter decremented to 0.
PROGRAMMEDLINENUMBER	The LCD reached the user-programmed line number.
GFXFIFOUNDERFLOW	The input graphics FIFO goes underflow.
GFXENDWINDOW	The screen reached the end of the graphics window. All data for the graphics window are fetched from memory and displayed on the screen.
PALETTEGAMMALOADING	The palette/gamma table is loaded.
OCPERROR	L3 interconnect sent SResp = ERR.
VID1FIFOUNDERFLOW	The input video1 FIFO goes underflow.
VID1ENDWINDOW	The screen reached the end of video1 window. All data for the video window are fetched from the memory and displayed on the screen.
VID2FIFOUNDERFLOW	The input video2 FIFO goes underflow.
VID2ENDWINDOW	The screen reached the end of video2 window. All data for the video window are fetched from the memory and displayed on the screen.
SYNCLOST	Interrupt occurs when VSYNC width/front or back porches are not wide enough to load the pipelines with data (LCD output).
SYNC_LOST_DIGITAL	Interrupt occurs when the display controller is not ready to output data when a digital request occurs. This interrupt informs that the timings of the NTSC/PAL video encoder are not set correctly.
WAKEUP	Occurs when the wakeup signal is asserted

(1) EVYNC interrupts (EVSYNC_EVEN and EVSYNC_ODD) are external interrupts received by the display controller and generated by the video encoder (VENC) module.

NOTE: To clear a synchronization lost interrupt, follow this sequence:

1. Clear the DSS.DISPC_CTRL[0] LCD_EN (LCD: SYNCLOST interrupt) or DSS.DISPC_CTRL[1] DIGITAL_EN (TV: SYNC_LOST_DIGITAL interrupt) bits.

   Check the interrupts.

   LCD: Verify that a FRAMEDONE interrupt occurs.

   TV : Verify that EVSYNC_EVEN or EVSYNC_ODD interrupts occur.
2. Set the DSS.DSS_SYSCONFIG[1] SOFTRESET bit to reset the display subsystem.
3. Set the display subsystem registers again.

NOTE: The SYNC_LOST_DIGITAL interrupts, which occur before the first VSYNC pulse signal (from the video encoder), must not be considered.

After the first VSYNC pulse signal, the SYNC_LOST_DIGITAL interrupt status bit must be cleared by writing 1 in the DSS.DISPC_IRQSTS[15] SYNC_LOST_DIGITAL bit; then the SYNC_LOST_DIGITAL interrupt can be enabled by setting the DSS.DISPC_IRQEN[15] SYNC_LOST_DIGITAL bit.

13.4 Programming Model

This section describes how to configure the display subsystem for the desired functionalities and also describes the programming models of the display controller, the RFBI and the video encoder.

The main configuration scenarios are:

- LCD panel support (bypass or RFBI mode)

  Configure the RFBI module (only if in RFBI mode; otherwise, the default values must remain), and then configure the display controller to the desired functionalities before the activities start.
- TV set support

  Configure the video encoder and then the display controller.
- Both LCD panel support (bypass or RFBI mode) and TV set support

  Configure the RFBI module (only if in RFBI mode; otherwise, leave the default values), configure the video encoder, and then configure the display controller.

13.4.1 Display Subsystem Reset

The display subsystem can receive a software reset that is propagated through all of the submodules to initialize the subsystem. The following procedure describes a possible sequence:

1. If the LCD is on, stop the LCD by setting the DSS.DISPC_CTRL[0] LCD_EN bit to 0.
   a. Reset the frame done status bit by writing 1 in the DSS.DISPC_IRQSTS[0] FRMDONE bit.
   b. Wait until the DSS.DISPC_IRQSTS[0] FRMDONE bit is set to 1. This shows that the end of frame has taken place and the LCD stop is complete.
2. To take the display subsystem out of reset, all clocks related to the display subsystem must be enabled and the DPLL4 must be enabled. The following clocks must be enabled to take the display subsystem out of reset:
   - PRCM.CM_FCLKEN_DSS[0] EN_DSS1 bit set to 1
   - PRCM.CM_FCLKEN_DSS[1] EN_DSS2 bit set to 1
   - PRCM.CM_FCLKEN_DSS[2] EN_TV bit set to 1
   - PRCM.CM_ICLKEN_DSS[0] EN_DSS bit set to 1

   Once the clocks are enabled as shown, the display subsystem can be taken out of reset.
3. Write 1 in the DSS.DSS_SYSCONFIG[1] SOFTRESET bit to apply the soft reset to the subsystem.
4. Read the DSS.DSS_SYSSTS[0] RESETDONE bit. If this bit is 1, the reset sequence is complete; otherwise, read this bit again (the reset sequence is not completed).

13.4.2 Display Subsystem Configuration Phase

The display subsystem configuration phase is important to configure the data flow for using the LCD panel or the TV set. Use the following flow:

1. To configure the top level of the functional clock of the display controller clock, set the DSS.DSS_CONTROL[0] DSS_CLK_SWITCH bit.
2. To configure the top level of the video encoder, set the DSS.DSS_CONTROL[2] VENC_CLOCK_MODE bit and the DSS.DSS_CONTROL[3] VENC_CLOCK_X4_EN bit for TV set support.
3. To configure the top level of the DAC stage, set the DSS.DSS_CONTROL[4] DAC_DEMEN bit for TV set support (if required).
4. Configure the RFBI module and/or the video encoder as needed.
5. Configure the display controller.

13.4.3 Display Controller Basic Programming Model

Some display controller registers are termed *shadow registers*, which are associated with the digital output and/or the LCD output. A shadow register change has no direct effect on the configuration of the display controller unless the DSS.DISPC_CTRL[5] GO_LCD bit is set for the LCD output and/or the DSS.DISPC_CTRL[6] GO_DIGITAL bit is set for the digital output.

In the case of the digital output, after programming the shadow registers, the DSS.DISPC_CTRL[6] GO_DIGITAL bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the external EVSYNC.

In the case of the LCD output, after programming the shadow registers, the DSS.DISPC_CTRL[5] GO_LCD bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the VFP start period.

Before setting either the DSS.DISPC_CTRL[5] GO_LCD or DSS.DISPC_CTRL[6] GO_DIGITAL bit, ensure that the bit is cleared.

Table 13-21 lists the shadow registers.

Table 13-21. Shadow Registers

Shadow Register Name	Updated on VFP Start Period (LCD output)	Updated on External VSYNC (Digital output)
DSS.DISPC_CTRL	X[1]	X[1]
DSS.DISPC_CFG	X	X
DSS.DISPC_DEFAULT_COLOR_m (m = 0)	X	
DSS.DISPC_DEFAULT_COLOR_m (m = 1)		X
DSS.DISPC_TRANS_COLOR_m (m = 0)	X	
DSS.DISPC_TRANS_COLOR_m (m = 1)		X
DSS.DISPC_LINE_NUMBER	X	
DSS.DISPC_TIMING_H	X	
DSS.DISPC_TIMING_V	X	
DSS.DISPC_POL_FREQ	X	
DSS.DISPC_DIVISOR	X	
DSS.DISPC_SIZE_DIG		X
DSS.DISPC_SIZE_LCD	X	
DSS.DISPC_GFX_BAj (j = 0,1)	X	X
DSS.DISPC_GFX_POSITION	X	X
DSS.DISPC_GFX_SIZE	X	X
DSS.DISPC_GFX_ATTRS	X	X
DSS.DISPC_GFX_FIFO_THR	X	X
DSS.DISPC_GFX_ROW_INC	X	X
DSS.DISPC_GFX_PIXEL_INC	X	X
DSS.DISPC_GFX_WINDOW_SKIP	X	X
DSS.DISPC_GFX_TBL_BA	X	X
DSS.DISPC_GFX_PRELOAD	X	X
DSS.DISPC_CPR_COEF_R	X	
DSS.DISPC_CPR_COEF_G	X	
DSS.DISPC_CPR_COEF_B	X	
DSS.DISPC_VIDn_BAj (j= 0,1)	X	X
DSS.DISPC_VIDn_POSITION	X	X
DSS.DISPC_VIDn_SIZE	X	X
DSS.DISPC_VIDn_ATTRS	X	X

---

(1) Some of the register bit fields are shadow bits. For more information, see Section 13.6, *Display Subsystem Register Manual*.

Table 13-21. Shadow Registers (continued)

Shadow Register Name	Updated on VFP Start Period (LCD output)	Updated on External VSYNC (Digital output)
DSS.DISPC_VIDn_FIFO_THR	X	X
DSS.DISPC_VIDn_ROW_INC	X	X
DSS.DISPC_VIDn_PIXEL_INC	X	X
DSS.DISPC_VIDn_FIR	X	X
DSS.DISPC_VIDn_PICTURE_SIZE	X	X
DSS.DISPC_VIDn_ACCUl (l = 0,1)	X	X
DSS.DISPC_VIDn_FIR_COEF_H_i (i = 0 to 7)	X	X
DSS.DISPC_VIDn_FIR_COEF_HV_i (i = 0 to 7)	X	X
DSS.DISPC_VIDn_FIR_COEF_Vi (i = 0 to 7)	X	X
DSS.DISPC_VIDn_CONV_COEFi (i = 0 to 4)	X	X
DSS.DISPC_VIDn_PRELOAD	X	X
DSS.DISPC_DATA_CYCLEk (k = 0 to 3)	X	

13.4.3.1 Display Controller Configuration

The following registers define the display controller configuration:

- DSS.DISPC_SYSCFG
- DSS.DISPC_SYSSTS
- DSS.DISPC_IRQSTS
- DSS.DISPC_IRQEN

13.4.3.2 Graphics Layer Configuration

The graphics layer configuration is common to the LCD and the TV set.

13.4.3.2.1 Graphics DMA Registers

The following registers define the graphics DMA engine configuration:

- DSS.DISPC_CTRL
- DSS.DISPC_GFX_BAj
- DSS.DISPC_GFX_ATTRS
- DSS.DISPC_GFX_ROW_INC
- DSS.DISPC_GFX_PIXEL_INC
- DSS.DISPC_GFX_FIFO_THR
- DSS.DISPC_GFX_TBL_BA

The following fields define the attributes of the graphics DMA engine:

- Graphics layer enable (DSS.DISPC_GFX_ATTRS[0] GFX_EN bit): The default value of this bit at reset time is 0x0 (Disabled). The graphics DMA engine fetches encoded pixels from the system memory only when the graphics layer is enabled (a valid configuration is programmed for the graphics layer). The graphics window is present and the graphics pipeline is active.
- Burst size (DSS.DISPC_GFX_ATTRS[7:6] GFX_BURST_SIZE field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests because the burst size must be aligned to the burst boundary.
- Preload configuration (DSS.DISPC_GFX_ATTRS[11] GFX_FIFO_PRELOAD bit): The default preload configuration uses the DSS.DISPC_GFX_PRELOAD register value (the reset value is 256 bytes) to

define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the DSS.DISPC_GFX_ATTRS[11] GFX_FIFO_PRELOAD bit, software users select between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008, respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:

  - Active matrix (TFT) display: DSS.DISPC_GFX_PRELOAD[11:0] PRELOAD = 0x60 (value is 96)
  - Color passive matrix (STN) display: DSS.DISPC_GFX_PRELOAD[11:0] PRELOAD = 0x72 (value is 114)
  - Monochrome passive matrix (STN) display: DSS.DISPC_GFX_PRELOAD[11:0] PRELOAD = 0xE0 (value is 224)

- Base address of the graphics buffer in system memory (DSS.DISPC_GFX_BAj registers): The default value of these two registers at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on a pixel size boundary. In case of 4 BPP, the resolution is two pixels; for 2 BPP, resolution is four pixels; for 1 BPP, resolution is eight pixels; and for RGB24 packed format, the resolution is four pixels. The vertical resolution is one line. The register DSS.DISPC_GFX_BA0 defines the base address of the even field; and DSS.DISPC_GFX_BA1 defines the base of the odd field in the case of an external synchronization and based on the value of the input signal DISPC_FID and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Graphics FIFO threshold (DSS.DISPC_GFX_FIFO_THR register): The low threshold (DSS.DISPC_GFX_FIFO_THR[11:0] GFX_FIFO_LOW_THR) and the high threshold (DSS.DISPC_GFX_FIFO_THR[27:16] GFX_FIFO_HIGH_THR) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. A request is issued as long as the FIFO has enough space available to accept a burst. The DMA engine then waits until the low level is reached to restart the requests. By setting the DSS.DISPC_CFG[14] FIFO_MERGE bit to 1, users merge the three FIFOs (GFX, VID1, and VID2). In this case, the low threshold (the DSS.DISPC_GFX_FIFO_THR[11:0] GFX_FIFO_LOW_THR bit field) and the high threshold (DSS.DISPC_GFX_FIFO_THR[27:16] GFX_FIFO_HIGH_THR bit field) values must be programmed with a multiplier factor of three (3 x value). By default, the FIFOs are not merged (the DSS.DISPC_CFG[14] FIFO_MERGE bit reset value is 0).
- Palette/gamma table used (DSS.DISPC_CFG[3] PALETTEGAMMA_TBL bit): The bit indicates if the palette must be loaded before the graphics data for the following frame. The bit is set by software and reset by hardware.
- Base address of the palette/gamma table buffer in system memory (DSS.DISPC_GFX_TBL_BA register): The default value of this register at reset time is 0x0. The base address is aligned on a 32-bit address. Depending on the pixel size of graphics data (1, 2, 4, or 8 BPP), 16 (1, 2, or 4 BPP), or 256 (8 BPP) x 32-bit values are loaded from system memory into the internal table memory. To load the table when using the memory as a gamma table, the graphics pipeline is enabled and then disabled by the software when the palette loaded interrupt is generated. The overlay manager ignores the graphics pipe when the table is used as a gamma table.

NOTE: In case of RGB16 format and optimization enabled, the base address is aligned on a 32-bit boundary and the number of bytes to skip is a multiple of 4 bytes.

- Graphics Priority (DSS.DISPC_GFX_ATTRS[14] GFX_ARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the graphics channel vs. video channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For that is, pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Graphics Self-Refresh (DSS.DISPC_GFX_ATTRS[15] GFX_SELF_REFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.

The sequence to activate the self-refresh is the following:

- Frame t: The bit field should be set at anytime during frame
- Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
- Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels

The sequence to deactivate the self-refresh is the following:

- Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame
- Frame t+1: Fetch of the data from system memory using the L3 interconnect

13.4.3.2.2 Graphics Layer Configuration Registers

The following registers define the graphics layer configuration:

- DSS.DISPC_CFG
- DSS.DISPC_GFX_POSITION
- DSS.DISPC_GFX_SIZE
- DSS.DISPC_GFX_ATTRS

The graphics layer is enabled/disabled by setting/resetting the DSS.DISPC_GFX_ATTRS[0] GFX_EN bit. When the graphics layer is disabled, the graphics window does not exist on the screen and the graphics pipeline and DMA are inactive.

Set a valid configuration before enabling the graphics layer. After a register change, either the DSS.DISPC_CTRL[6] GO_DIGITAL or DSS.DISPC_CTRL[5] GO_LCD bit must be set. The software must wait for the hardware to reset the bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

13.4.3.2.3 Graphics Window Attributes

The following fields define the attributes of the graphics window:

- Graphics format (DSS.DISPC_GFX_ATTRS[4:1] GFX_FMT bit field): The default value of this bit field at reset time is 0x0 (BITMAP 1-BPP). The graphics format can be either: BITMAP1, BITMAP2, BITMAP4, or BITMAP8 (CLUT) or RGB12, RGB16, or RGB24 (true-color formats).
- Graphics window X-position (DSS.DISPC_GFX_POSITION[10:0] GFX_POSX bit field): The default value at reset time is 0x0. The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Graphics window Y-position (DSS.DISPC_GFX_POSITION[26:16] GFX_POSY bit field): The default value of this bit field at reset time is 0x0.The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Graphics window width (DSS.DISPC_GFX_SIZE[10:0] GFX_SIZEX bit field): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed for the following formats: 8 BPP, RGB12, RGB16, and RGB24. The width must be a multiple of eight pixels for 1 BPP, four pixels for 2 BPP, and two pixels for 4 BPP. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width of the graphics window (in bytes) is a multiple of the graphics burst size defined in the DSS.DISPC_GFX_ATTRS[7:6] GFX_BURST_SIZE bit field (in bytes).

NOTE: When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the DSS.DISPC_GFX_ROW_INC register is not 1. When DSS.DISPC_GFX_ROW_INC register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the graphics window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the graphics layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

- Graphics window height (DSS.DISPC_GFX_SIZE[26:16] GFX_SIZEY bit field): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the graphics window must be inside the LCD screen.

Depending on the height of the buffer to be displayed in the graphics layer and the position, the height should be adjusted by software to limit the bottom edge of the window inside the screen

- Graphics data endianness (DSS.DISPC_GFX_ATTRS[10] GFX_ENDIAN bit): This bit indicates the endianness (little or big) of the graphics pixels. The default value at reset time is 0x0 (little endian).
- Graphics data nible mode (DSS.DISPC_GFX_ATTRS[9] GFX_NIBBLE_MODE bit): This bit indicates the nibble mode of the graphics pixels. The default value at reset time is 0x0 (Disable).
- Graphics replication logic enable (DSS.DISPC_GFX_ATTRS[5] GFX_REPLICATION_EN bit): The default value at reset time is 0x0 (Disable). The encoded pixel data in RGB format (RGB16) can be extended to 24-bit format with or without replication of the MSB part to fill up the LSB due to the 24-bit left alignment. If the replication logic is turned off, the LSB part is filled up with 0s.
- Graphics window skip enable (DSS.DISPC_CTRL[12] OVLY_OPT bit): By setting/resetting the bit, the overlay optimization is enabled or disabled. Before enabling the overlay optimization, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFX_WINDOW_SKIP bit field must be set according to the video1 and graphics windows overlap. The default value at reset time is 0x0 (Disable). When video1 is not present, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFX_WINDOW_SKIP bit field should be reset. When the color key is used, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFX_WINDOW_SKIP bit field should be reset.
- Graphics window skip (DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFX_WINDOW_SKIP bit field): The bit field represents the number of bytes to skip while fetching the graphics-encoded pixels when reaching the beginning of the video window. The optimization allows fetching only the visible graphics pixels. The color key cannot be selected because the graphics pixels under the video window are not present. The default value at reset time is 0x0 (0 byte).

Figure 13-54 through Figure 13-57 give examples of how to program the GFX_WINDOW_SKIP field for overlay optimization:

Figure 13-54. Overlay Optimization: Case 1

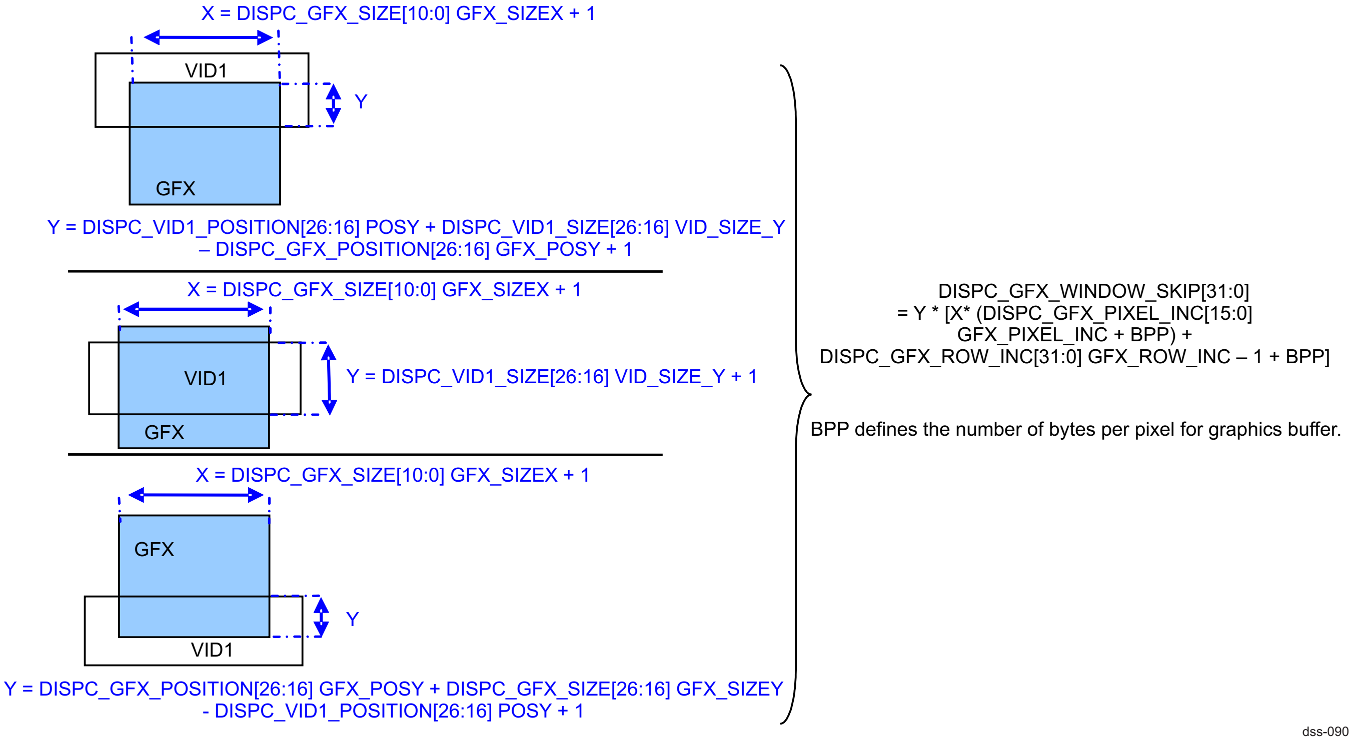


Figure 13-55. Overlay Optimization: Case 2

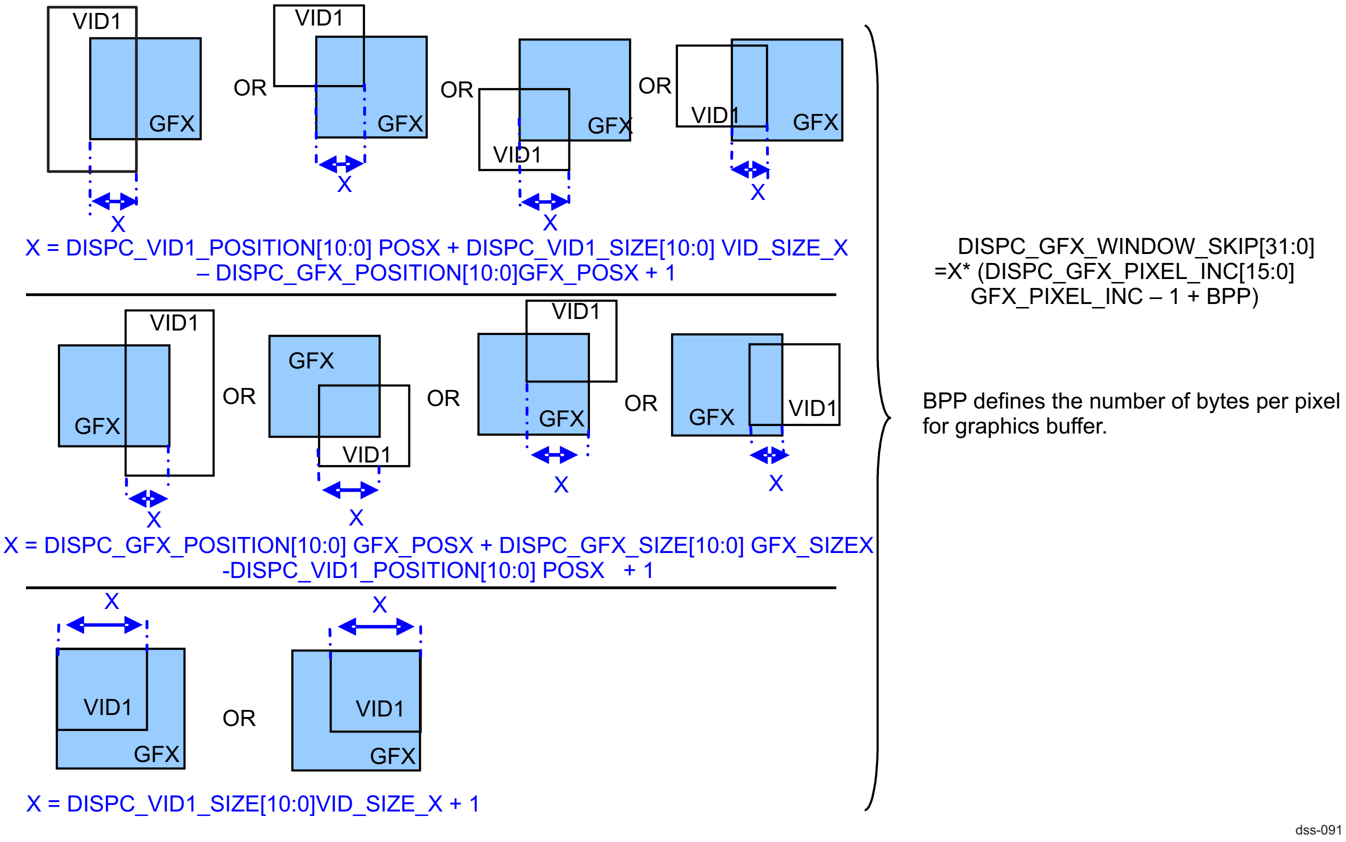

Figure 13-56. Overlay Optimization: Case 3

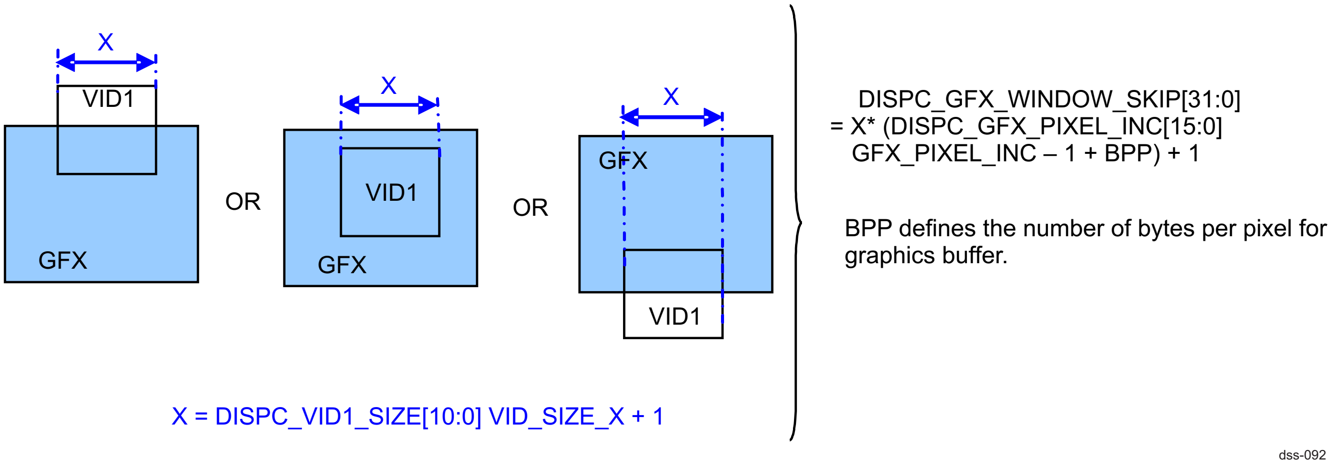

Figure 13-57. Overlay Optimization: Case 4

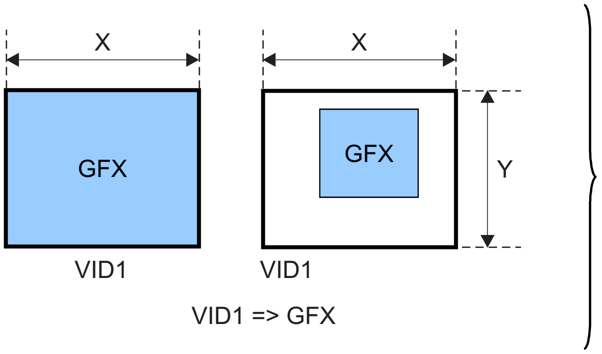

When the VID1 window overlaps the GFX window equally or more, the DISPC_GFX_ATTRS[0] GFX_EN bit should be clear.

camdss-093

13.4.3.3 Video Layer Configuration

The video layer configuration is common to the LCD and the TV set.

13.4.3.3.1 Video DMA Registers

The following registers define the video DMA engine configuration:

- DSS.DISPC_CTRL
- DSS.DISPC_VIDn_BAj
- DSS.DISPC_VIDn_ATTRS
- DSS.DISPC_VIDn_ROW_INC
- DSS.DISPC_VIDn_PIXEL_INC
- DSS.DISPC_VIDn_FIFO_THR
- DSS.DISPC_VIDn_PICTURE_SIZE

The following fields define the attributes of the graphics DMA engine:

- Video layer enable (DSS.DISPC_VIDn_ATTRS[0] EN bit): The default value of this bit at reset time is 0x0 (Disabled). The video DMA engine fetches encoded pixels from the system memory only when the video layer is enabled (a valid configuration is programmed for the video layer). The video window is present and the video pipeline is active.
- Burst size (DSS.DISPC_VIDn_ATTRS[15:14] BURST_SIZE bit field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This bit field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests, because the burst size must be aligned to the burst boundary.
- Preload configuration (DSS.DISPC_VIDn_ATTRS[19] FIFO_PRELOAD bit): The default preload configuration uses the DSS.DISPC_VIDn_PRELOAD register value (the reset value is 256 bytes) to define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the DSS.DISPC_VIDn_ATTRS[19] FIFO_PRELOAD bit, software users select between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008, respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:
  - Active matrix (TFT) display: DSS.DISPC_VIDn_PRELOAD[11:0] PRELOAD = 0xB0 (value is 176)
  - Color passive matrix (STN) display: DSS.DISPC_VIDn_PRELOAD[11:0] PRELOAD = 0x110 (value is 272)
  - Monochrome passive matrix (STN) display: DSS.DISPC_VIDn_PRELOAD[11:0] PRELOAD = 0x1B0 (value is 432)

- Base address of the video buffer in system memory (DSS.DISPC_VIDn_BAj registers): The default value at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on pixel size boundary. In case of YCbCr 4:2:2 formats, the resolution is 2 pixels. In case of RGB24 packed format, the resolution is 4 pixels. The vertical resolution is one line. The register DSS.DISPC_VIDn_BA0 defines the base address of the even field, and DSS.DISPC_VIDn_BA1 defines the base of the odd field in the case of an external synchronization and based on the value of the input signal DISPC_FID and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Video FIFO threshold (DSS.DISPC_VIDn_FIFO_THR register): The low threshold (DSS.DISPC_VIDn_FIFO_THR[11:0] VID_FIFO_LOW_THR) and the high threshold (DSS.DISPC_VIDn_FIFO_THR[27:16] VID_FIFO_HIGH_THR) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. A request is issued as long as the FIFO has enough space available to accept a burst. The DMA engine then waits until the low level is reached to restart the requests. By setting the DSS.DISPC_CFG[14] FIFO_MERGE bit to 1, users merge the three FIFOs (GFX, VID1, and VID2). In this case, the low threshold (the DSS.DISPC_VIDn_FIFO_THR[11:0] VID_FIFO_LOW_THR bit field with n corresponding to the active video channel 1 or 2) and the high threshold (DSS.DISPC_VIDn_FIFO_THR[27:16] VID_FIFO_HIGH_THR bit field with n corresponding to the active video channel 1 or 2) values must be programmed with a multiplier factor of three (3 x value). By default, the FIFOs are not merged (the DSS.DISPC_CFG[14] FIFO_MERGE bit reset value is 0).
- Video buffer width (DSS.DISPC_VIDn_PICTURE_SIZE[10:0] VID_ORG_SIZE_X): The default value at reset time is 0x0 (1 pixel). The buffer width in system memory is from 1 up to 2048 pixels. All the integer values in the range [1:2048] are allowed. Software users must program this bit field to the value minus 1.
- Video buffer height (DSS.DISPC_VIDn_PICTURE_SIZE[26:16] VID_ORG_SIZE_Y): The default value at reset time is 0x0 (1 pixel). The buffer height in system memory is from 1 up to 2048 pixels. All the integer values in the range [1:2048] are allowed. Software users must program this field to the value minus 1.
- Video data endianness (DSS.DISPC_VIDn_ATTRS[17] ENDIAN bit, with n=1 or 2): This bit indicates the endianness (little or big) of the video pixels. The default value at reset time is 0x0 (little endian).

13.4.3.3.2 Video Configuration Register

The following shadow registers define video layer n (with n = 1 or 2) configuration:

- DSS.DISPC_CFG
- DSS.DISPC_VIDn_POSITION
- DSS.DISPC_VIDn_SIZE
- DSS.DISPC_VIDn_ATTRS
- DSS.DISPC_VIDn_FIR
- DSS.DISPC_VIDn_PICTURE_SIZE
- DSS.DISPC_VIDn_FIR_COEF_H_i (with i = 0 to 7)
- DSS.DISPC_VIDn_FIR_COEF_HV_i (with i = 0 to 7)
- DSS.DISPC_VIDn_CONV_COEFi (with i = 0 to 4)
- The video layer n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRS[0] EN field. If the video layer is disabled, the video window does not exist on the screen and the whole video pipeline and DMA are inactive. Before enabling the video layer, a valid configuration must be set. After a register change, either the DSS.DISPC_CTRL[6] GO_DIGITAL or DSS.DISPC_CTRL[5] GO_LCD bit must be set. The software must wait for the hardware to reset the bit before setting this bit. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

13.4.3.3.3 Video Window Attributes

The following fields define the attributes of video window n:

- Video format (DSS.DISPC_VIDn_ATTRS[4:1] FMT bit field, with n = 1 or 2): The default value at reset time is 0x0 (BITMAP 1 BPP, nonsupported format by the video pipeline).The video format can be RGB16, RGB24, YUV2 4:2:2 co-DSS sited, and UYVY 4:2:2 co-sited.
- Video window X-position (DSS.DISPC_VIDn_POSITION[10:0] POSX bit field, with n = 1 or 2): The default value at reset time is 0x0 (first column starting on the left edge of the screen). The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Video window Y-position (DSS.DISPC_VIDn_POSITION[26:16] POSY bit field, with n = 1 or 2): The default value at reset time is 0x0 (first row starting at the top of the screen). The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Video window width (DSS.DISPC_VIDn_SIZE[10:0] VID_SIZE_X bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video window is a multiple of the video burst size defined in the DSS.DISPC_VIDn_ATTRS[15:14] VID_BURST_SIZE bit field (in bytes).

NOTE: When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the DSS.DISPC_VIDn_ROW_INC register is not 1. When the DSS.DISPC_VIDn_ROW_INC register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the video window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the video layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

- Video window height (DSS.DISPC_VIDn_SIZE[26:16] VID_SIZE_Y bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the video window must be inside the LCD screen. Depending on the height of the buffer to be displayed in the video layer and the position, the height should be adjusted by software to limit the bottom edge of the window inside the screen.
- Video picture width in system memory (DSS.DISPC_VIDn_PICTURE_SIZE[10:0] VID_ORG_SIZE_X bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed with RGB16 and RGB24 video data. For YUV2 4:2:2 and UYVY 4:2:2 formats, the width must be a multiple of two pixels. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video picture is a multiple of the video burst size defined in the DSS.DISPC_VIDn_ATTRS[15:14] VID_BURST_SIZE bit field (in bytes).
- Video picture height in system memory (the DSS.DISPC_VIDn_PICTURE_SIZE[26:16] VID_ORG_SIZE_Y bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed.
- Video Priority (DSS.DISPC_VIDn_ATTRS[23] ARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the video channel vs. other channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For that is, pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Video Self-Refresh (DSS.DISPC_VIDn_ATTRS[24] SELF_REFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.
  The sequence to activate the self-refresh is the following:
  - Frame t: The bit field should be set at anytime during frame
  - Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
  - Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels

  The sequence to deactivate the self-refresh is the following:
  - Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame
  - Frame t+1: Fetch of the data from system memory using the L3 interconnect

13.4.3.3.4 Video Up-/Down-Sampling Configuration

The video horizontal up/downsampling block for video pipeline n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRS[5] RESIZE_EN bit.

The video vertical up/downsampling block for video pipeline n is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRS[6] RESIZE_EN bit.

Set a valid configuration before enabling the video up/downsampling block.

NOTE: Vertical and horizontal downsampling are limited to a 1/4 resize factor.

After a register change, either the DSS.DISPC_CTRL[6] GO_DIGITAL or DSS.DISPC_CTRL[5] GO_LCD bit must be set. The software must wait until the hardware resets this bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

The following fields define the configuration of the video up/downsampling block for video pipeline n:

- Vertical up/downsampling increment value (DSS.DISPC_VIDn_FIR[27:16] FIR_V_INC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$FIR\_V\_INC[12:0] = 1024 \text{ x } \left(\frac{VID\_ORG\_SIZE\_Y[10:0]}{VID\_SIZE\_Y[10:0]}\right) \tag{8}$$

dss-E093

NOTE:

- If the FIR_V_INC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VID_SIZE_Y[10:0] equals 0x1, VID_SIZE_Y[10:0] is replaced by 0x2 in the previous equation.
- The VID_ORG_SIZE_Y[10:0] and VID_SIZE_Y[10:0] bit field values must be programmed with the value desired minus 1.

- Horizontal up/downsampling increment value (DSS.DISPC_VIDn_FIR[11:0] FIR_H_INC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$FIR\_H\_INC[12:0] = 1024 \text{ x } \left(\frac{VID\_ORG\_SIZE\_X[10:0]}{VID\_SIZE\_X[10:0]}\right) \tag{9}$$

dss-E094

NOTE:

- If the FIR_H_INC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VID_SIZE_X[10:0] equals 1, VID_SIZE_X[10:0] is replaced by 2 in the previous equation.
- The VID_ORG_SIZE_X[10:0] and VID_SIZE_X[10:0] bit field values must be programmed with the value desired minus 1.

- Vertical up/downsampling accumulator value (DSS.DISPC_VIDn_ACCUl[25:16] VERTICAL_ACCU bit field): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the vertical filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see Table 13-22).
- Vertical up/downsampling line buffer configuration (DSS.DISPC_VIDn_ATTRS[22] LINE_BUFFER_SPLIT bit): The default value at reset time is 0x0 (line buffers are not split). The backward compatibility is maintained versus OMAP2420 and OMAP2430 devices. When the bit field is set, each line buffer is split into two line buffers to be able to use six line buffers instead of three.
- Vertical up/downsampling line buffer configuration (DSS.DISPC_VIDn_ATTRS[21] VERTICAL_TAPS bit): The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used. The backward compatibility is maintained versus OMAP2420 and OMAP2430 devices. When the bit field is set, the 5-tap configuration is used and the

DSS.DISPC_VIDn_ATTRS[22] LINE_BUFFER_SPLIT bit must be set to 1.

- Vertical up/downsampling line buffer configuration (DSS.DISPC_VIDn_ATTRS[20] OPTIMIZATION bit): The default value at reset time is 0x0 (no optimization). If the bit is set, the DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV4:2:2) while doing 90- and 270-degree rotation. If the bit is clear, the DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV4:2:2) while doing 90- and 270-degree rotation. The width and height of picture should be even to use the optimization. Even width is required for the input picture when the 5-tap configuration is used.

NOTE: If the 5-tap resizer is used for RGB16 and YUV4:2:2 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels. This leads to the following register configuration:

DISPC_VIDn_ATTRS[21] VERTICAL_TAPS == 1
DISPC_VIDn_PICTURE_SIZE[10:0] VID_ORG_SIZE_X 4 and even

- Horizontal up/downsampling accumulator value (DSS.DISPC_VIDn_ACCUl[9:0] HORIZONTAL_ACCU bit field): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the horizontal filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see Table 13-22).

Table 13-22. Vertical/Horizontal Accumulator Phase

Accumulator Value	Phases f
0	0
128	1
256	2
384	3
512	4
640	5
768	6
896	7

- Vertical up/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_HV_i registers, with n = 1 or 2, i = 0 to 7): The 3-tap vertical up/downsampling coefficients are defined in these registers. There are eight registers for the eight phases with three coefficients for each, or a total of 24 programmable coefficients for the vertical up/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one).

  In addition, there are 2-tap vertical up/downsampling coefficients defined in DSS.DISPC_VIDn_FIR_COEF_Vi registers. There are 8 registers for the 8 phases with 2 coefficients for each of them so a total of 16 programmable coefficients for the vertical up/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients. In case of 5-tap configuration, both sets of registers DSS.DISPC_VIDn_FIR_COEF_HV_i and DSS.DISPC_VIDn_FIR_COEF_Vi are used. In case of 3-tap configuration, only one set of registers DSS.DISPC_VIDn_FIR_COEF_HV_i is used.
- Horizontal up/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_H_i and DISPC_VIDn_FIR_COEF_HV_i registers, with n = 1 or 2, i = 0 to 7): The DSS.DISPC_VIDn_FIR_COEF_H_i register and the DSS.DISPC_VIDn_FIR_COEF_HV_i register define the 5-tap horizontal up/downsampling coefficients. There are eight registers for the eight phases with five coefficients for each register, or a total of 40 programmable coefficients for the horizontal up/downsampling block.

  Each DSS.DISPC_VIDn_FIR_COEF_H_i register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one). Each DSS.DISPC_VIDn_FIR_COEF_HV_i register contains one 8-bit signed coefficient.

  The programmable coefficient for the FIR up/downsampling method must be adjusted based on application needs. For more details on scaling programming settings, see Section 13.5.1.

13.4.3.3.5 Video Color Space Conversion Configuration

The DSS.DISPC_VIDn_CONV_COEFi registers (with i = 0 to 4) has nine 11-bit coefficients defined for the programmable color space conversion block for video pipeline n (with n = 1 or 2).

The standard register coefficients are:

YCbCr-to-RGB Registers (VidFullRange=0)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix} \tag{10}$$

dssE095

YCbCr to RGB Registers (VidFullRange=1)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix} \tag{11}$$

dss-E096

Table 13-23 lists the color space conversion register values.

Table 13-23. Color Space Conversion Register Values

Coefficients	BT.601-5	BT.601-5 Range [0:255]	BT.709	BT.709 Range [0:255]
RY	298	256	298	256
RCr	409	351	459	394

BCb	517	443	541	465
VidFullRange	0	1	0	1

13.4.3.4 LCD-Specific Control Registers

The following registers define the LCD output configuration:

- DSS.DISPC_CTRL
- DSS.DISPC_CFG
- DSS.DISPC_DEFAULT_COLOR_m (m=0)
- DSS.DISPC_TRANS_COLOR_m (m=0)
- DSS.DISPC_TIMING_H
- DSS.DISPC_TIMING_V
- DSS.DISPC_POL_FREQ
- DSS.DISPC_DIVISOR
- DSS.DISPC_SIZE_LCD
- DSS.DISPC_DATA_CYCLEk

- DSS.DISPC_CPR_COEF_R, DSS.DISPC_CPR_COEF_G, DSS.DISPC_CPR_COEF_B

Setting/resetting the DSS.DISPC_CTRL[0] LCD_EN bit enables/disables the LCD output. A valid configuration must be set before enabling the LCD output.

13.4.3.4.1 LCD Attributes

The following fields define the attributes of the panel connected to the display controller:

- Monochrome or color panel (the DSS.DISPC_CTRL[2] MONO_COLOR bit)
- Passive Matrix or active Matrix panel (the DSS.DISPC_CTRL[3] STNTFT bit)
- Color depth (the DSS.DISPC_CTRL[9:8] TFT_DATA_LINES bit field)
- Number of lines per panel (the DSS.DISPC_SIZE_LCD[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC_SIZE_LCD[10:0] PPL bit field)
- 4- or 8-bit interface for Passive Matrix monochrome panel (the DSS.DISPC_CTRL[4] M8B bit)

13.4.3.4.2 LCD Timings

The following bit fields define the timing generation of HSYNC/VSYNC:

- Horizontal front porch (the DSS.DISPC_TIMING_H[19:8] HFP bit field)
- Horizontal back porch (the DSS.DISPC_TIMING_H[31:20] HBP bit field)
- Horizontal synchronization pulse width (the DSS.DISPC_TIMING_H[7:0] HSW bit field)
- Vertical front porch (the DSS.DISPC_TIMING_V[19:8] VFP bit field)
- Vertical back porch (the DSS.DISPC_TIMING_V[31:20] VBP bit field)
- Vertical synchronization pulse width (the DSS.DISPC_TIMING_V[7:0] VSW bit field)
- On/Off control of HSYNC/VSYNC pixel clock (the DSS.DISPC_POL_FREQ[17] ONOFF bit)
- Program HSYNC/VSYNC rise or fall (the DSS.DISPC_POL_FREQ[16] RF bit)
- Invert HSYNC (the DSS.DISPC_POL_FREQ[13] IHS bit)
- Invert VSYNC (the DSS.DISPC_POL_FREQ[12] IVS bit)
- HSYNC gated (the DSS.DISPC_CFG[6] HSYNC_GATED bit)
- VSYNC gated (the DSS.DISPC_CFG[7] VSYNC_GATED bit)

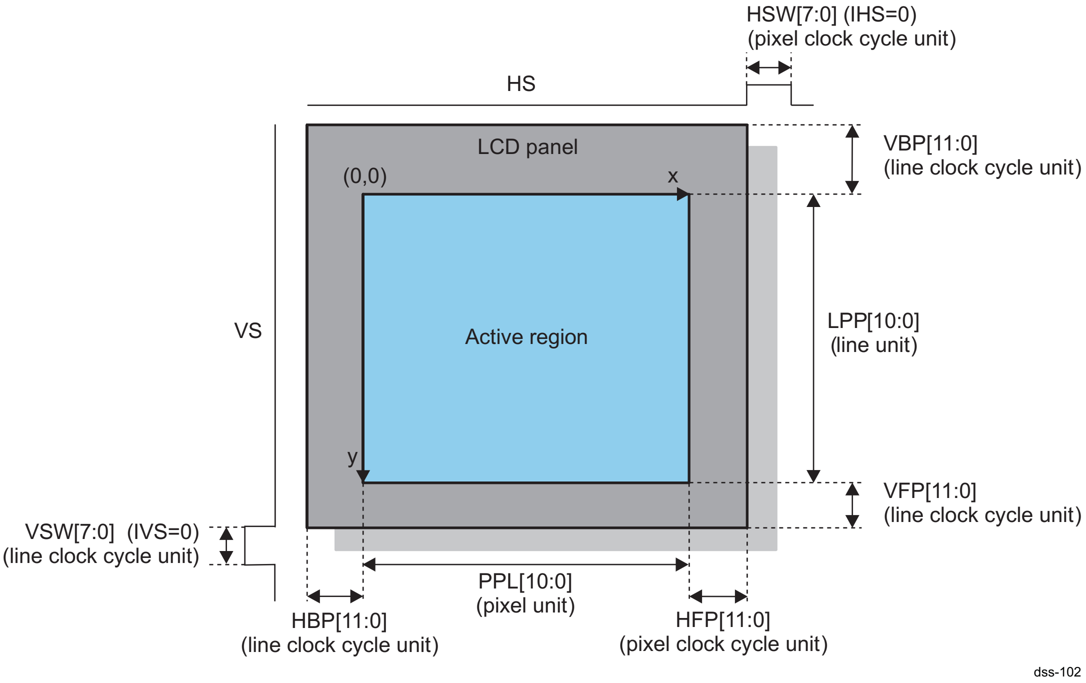
Table 13-24 describes the programming rules for LCD timing.

Table 13-24. Programming Rules

	No Downsampling	Downsampling H or V	Downsampling H + V
(HBP + HSW + HFP) * PCD	8	10	20

Figure 13-58 shows the timing values description in the case of an active matrix display.

Figure 13-58. Timing Values Description (Active Matrix Display)



The following bit fields define the timing generation of ac-bias (output enable in active matrix mode):

- Invert output enable (DSS.DISPC_POL_FREQ[15] IEO bit)
- ac-bias pin frequency (DSS.DISPC_POL_FREQ[7:0] ACB bit field)
- ac-bias pin transitions per interrupt (DSS.DISPC_POL_FREQ[11:8] ACBI bit field)
- ac-bias gated (DSS.DISPC_CFG[8] ACBIASGATED)

The following bit fields define the timing generation of the pixel clock:

- Pixel clock divisor (DSS.DISPC_DIVISOR[7:0] PCD bit field)
- Invert pixel clock (DSS.DISPC_POL_FREQ[14] IPC bit)
- Pixel clock gated (DSS.DISPC_CFG[5] PIXEL_CLK_GATED bit)

The 8-bit pixel clock divider (the DSS.DISPC_DIVISOR[7:0] PCD bit field) selects the pixel clock frequency. This bit field generates a range of pixel clock frequencies from LC/1 to LC/255, where LC is the logic clock from the divided functional clock of the display controller by the DSS.DISPC_DIVISOR[23:16] LCD bit field.

The pixel clock is defined by the following equation:

Pixel Clock = (FunctionalClock/LCD[7:0])/PCD[7:0]

Table 13-25 through Table 13-28 show the pixel clock frequency limitations depending the panel type (active or passive matrix) and the mode (color or monochrome).

Table 13-25. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Active Matrix Display

Min PCD Values			**Horizontal Resampling**				
			Off	**Up**	**1:1 - 1:2**	**1:2 - 1:3**	**1:3 - 1:4**
Vertical Resampling	Off		2 (1)(1)	2 (1)	2	3	4
	Up		2 (1)	2 (1)(1)	2	3	4
	1:1 - 1:2	3-tap	2	2	4	6	8
		5-tap	PCDmin	PCDmin	PCDmin	PCDmin	PCDmin
	1:2 - 1:4		PCDmin	PCDmin	PCDmin	PCDmin	PCDmin

---

(1) The PCD value can be 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the pixel clock.

Table 13-26. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Passive Matrix Display - Mono4

Min PCD Values			**Horizontal Resampling**				
			Off	**Up**	**1:1 - 1:2**	**1:2 - 1:3**	**1:3 - 1:4**
Vertical Resampling	Off		4	4	8	12	16
	Up		4	4	8	12	16
	1:1 - 1:2	3-tap	8	8	16	24	32
		5-tap	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin
	1:2 - 1:4		4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin

Table 13-27. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Passive Matrix Display - Mono8

Min PCD Values			**Horizontal Resampling**				
			Off	**Up**	**1:1 - 1:2**	**1:2 - 1:3**	**1:3 - 1:4**
Vertical Resampling	Off		8	8	16	24	32
	Up		8	8	16	24	32
	1:1 - 1:2	3-tap	16	16	32	48	64
		5-tap	8xPCDmin	8xPCDmin	4xPCDmin	8xPCDmin	8xPCDmin
	1:2 - 1:4		8xPCDmin	8xPCDmin	4xPCDmin	8xPCDmin	8xPCDmin

Table 13-28. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Passive Matrix Display - Color

Min PCD Values			**Horizontal Resampling**				
			Off	**Up**	**1:1 - 1:2**	**1:2 - 1:3**	**1:3 - 1:4**
Vertical Resampling	Off		3	3	6	9	12
	Up		3	3	6	9	12
	1:1 - 1:2	3-tap	6	6	12	18	24
		5-tap	3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin
	1:2 - 1:4		3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin

NOTE: In case of RGB24 format, Figure 13-59 is still valid, except the PCDmin values which must be multiplied by two.

The PCDmin for vertical downsampling only is defined by the following equations:

Figure 13-59. PCDmin Formulas (V Down-Sampling Only)

$$h\_ratio = \frac{DISPC\_SIZE\_LCD[10:0]PLL}{DISPC\_VIDn\_SIZE[10:0]VID\_SIZE\_X}$$

$$v\_ratio = \frac{DISPC\_VIDn\_PICTURE\_SIZE[10:0]VID\_ORG\_SIZE\_Y}{DISPC\_VIDn\_SIZE[10:0]VID\_SIZE\_Y}$$

$$PCD\min = \frac{v\_ratio}{2 \times h\_ratio} \quad 1 < v\_ratio \le 2$$

$$PCD\min = \max\left(\frac{v\_ratio}{2 \times h\_ratio}, \frac{v\_ratio - 2}{2 \times (h\_ratio - 1)}\right) \quad 2 < v\_ratio \le 4$$

dss-E103

The PCDmin for horizontal downsampling only is defined by the following formula:

While downsampling by n, *PCDmin = n*

For H+V downsampling, the formula is the following:

PCDmin = max(PCDmin H only, PCDmin V only) as defined above

The refresh rate depends on the following parameters:

- Horizontal front porch (the DSS.DISPC_TIMING_H[19:8] HFP bit field)
- Horizontal back porch (the DSS.DISPC_TIMING_H[31:20] HBP bit field)
- Horizontal synchronization pulse width (the DSS.DISPC_TIMING_H[7:0] HSW bit field)
- Vertical front porch (the DSS.DISPC_TIMING_V[19:8] VFP bit field)
- Vertical back porch (the DSS.DISPC_TIMING_V[31:20] VBP bit field)
- Vertical synchronization pulse width (the DSS.DISPC_TIMING_V[7:0] VSW bit field)
- Number of lines per panel (the DSS.DISPC_SIZE_LCD[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC_SIZE_LCD[10:0] PPL bit field)
- 4- or 8-bit interface for the passive matrix monochrome panel (the DSS.DISPC_CTRL[4] M8B bit)

The following bit fields define the behavior of the internal blocks:

- Spatial/temporal dithering logic enabled (DSS.DISPC_CTRL[7] ST_DITHER_EN bit)
- Spatial/temporal dithering logic number of frames (DSS.DISPC_CTRL[31:30] SPATIALTEMPORALDITHERFRAMES bit field). The default value of this bit field at reset time is 0x0, which is 1 frame only (spatial processing without temporal dithering). The possible values are 0x0 (one frame), 0x1 (two frames), and 0x2 (four frames). The number of frames is initialized before enabling the spatial/temporal dithering unit. The software must not change this bit field value while the spatial/temporal unit is enabled.

The following bit field defines the clock gating strategy:

- In active matrix mode, the pixel clock is always gated or only when valid data are present (the DSS.DISPC_CFG[0] PIXEL_GATED bit).

13.4.3.4.3 LCD Overlay

The following bit fields define the overlay attributes of the LCD output:

- Transparency color key (the DSS.DISPC_TRANS_COLOR0i register (i = 0))
- Transparency color key enable (the DSS.DISPC_CFG[10] TCK_LCD_EN bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.DISPC_CFG[11] TCK_LCD_SELECTION bit)
- The default solid background color is defined in the DSS.DISPC_DEFAULT_COLOR_m[23:0] DEFAULT_COLOR bit field (i=0).
- Alpha blender Enable (DSS.DISPC_CFG[18] LCD_ALPHABLDR_EN)
- Global alpha blending values (DSS.DISPC_GLOBAL_ALPHA[23:16] VID2_GLOBAL_ALPHA and DSS.DISPC_GLOBAL_ALPHA[7:0] GFX_GLOBAL_ALPHA). The value 0xFF corresponds to 100% opaque and 0 to 100% transparent

---

NOTE: The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

NOTE: When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

When all of these fields are set to the appropriate values, set the DSS.DISPC_CTRL[5] GO_LCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CTRL[0] LCD_EN bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CTRL[0] LCD_EN bit will be set to 1.

13.4.3.4.4 LCD TDM

The following fields define the multiple cycle output configuration:

- First cycle (the DSS.DISPC_DATA_CYCLEk (k=0) register)
- Second cycle (the DSS.DISPC_DATA_CYCLEk (k=1) register)
- Third cycle (the DSS.DISPC_DATA_CYCLEk (k=2) register)
- Enable (the DSS.DISPC_CTRL[20] TDM_EN bit)
- Parallel mode (the DSS.DISPC_CTRL[22:21] TDM_PARALLEL_MODE field)
- Cycle format (the DSS.DISPC_CTRL[24:23] TDM_CYCLE_FMT field)
- Unused bits (the DSS.DISPC_CTRL[26:25] TDM_UNUSED_BITS field)

When all of these bit fields are set to the appropriate values, set the DSS.DISPC_CTRL[5] GO_LCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CTRL[0] LCD_EN bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CTRL[0] LCD_EN bit will be set to 1.

13.4.3.4.5 LCD Spatial/Temporal Dithering

The following bit fields define the LCD spatial/temporal dithering configuration:

- Number of frames (the DSS.DISPC_CTRL[31:30] SPATIAL_TEMPORAL_DITHER bit field) with:
  - 0x0 Spatial only (default value)
  - 0x1 Spatial + Temporal over two frames
  - 0x2 Spatial + Temporal over four frames
  - 0x3 Reserved
- Enable (the DSS.DISPC_CTRL[7] ST_DITHER_EN bit)
  - 0x0 Disabled (default value)
  - 0x1 Enabled

When all of these bit fields are set to the appropriate values, set the DSS.DISPC_CTRL[5] GO_LCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CTRL[0] LCD_EN bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CTRL[0] LCD_EN bit will be set to 1.

13.4.3.4.6 LCD Color Phase Rotation

The following bit fields define the color phase rotation configuration:

- Enable (the DSS.DISPC_CFG[15] CPR bit)
  - 0x0 Disabled (default value)
  - 0x1 Enabled
- Red 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_R

register)

- Green 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_G register)
- Blue 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_B register)

The programmable color phase rotation block for the LCD output has nine 10-bit coefficients defined in the DSS.DISPC_CPR_COEF_R, DSS.DISPC_CPR_COEF_G, and DSS.DISPC_CPR_COEF_B, as described in Figure 13-60 through Figure 13-63.

Figure 13-60. Color Phase Rotation Matrix

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \left(\begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix} \right)$$

dss-E105

Figure 13-61. Color Phase Rotation Matrix (R Component Only)

$$Riout = \frac{1}{256} * (RR * Rin + RG * Gin + RB * Bin)$$

dss-E106

Figure 13-62. Color Phase Rotation Matrix (G Component Only)

$$Gout = \frac{1}{256} * (GR * Rin + GG * Gin + GB * Bin)$$

dss-E107

Figure 13-63. Color Phase Rotation Matrix (B Component Only)

$$Bout = \frac{1}{256} * (BR * Rin + BG * Gin + BB * Bin)$$

dss-E104

When all of these bit fields are set to the appropriate values, set the DSS.DISPC_CTRL[5] GO_LCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CTRL[0] LCD_EN bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CTRL[0] LCD_EN bit will be set to 1.

13.4.3.4.6.1 Color Phase Rotation - Diagonal Matrix

The Color Phase Rotation feature is useful when using an LCD backlight that is not white. By using a correct configuration of the R, G and B coefficients of CPR, the color bias of the screen can be corrected. The following paragraphs give an example of configuration of the CPR feature.

The easiest example of CPR configuration is a diagonal matrix. This way, the output colors depends on one input color only. Figure 13-64 gives the example of a diagonal matrix and the corresponding equation of the output components.

Figure 13-64. Diagonal Matrix Configuration

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \left(\begin{bmatrix} RR & 0 & 0 \\ 0 & GG & 0 \\ 0 & 0 & BB \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix} \right)$$

$$\longrightarrow Rout = \frac{1}{256} * \left(RR * Rin \right)$$

$$\longrightarrow Gout = \frac{1}{256} * \left(GG * Gin \right)$$

$$\longrightarrow Bout = \frac{1}{256} * \left(BB * Bin \right)$$

dss-200

According to these 3 new equations, each output component only depends on the corresponding input color. The coefficients can easily be used to reduce the impact of a non-white backlight.

Let's take the example of a "blue" backlight. In this case, users have the feeling that a blue film has been added on the screen, and then each color seems to be "too much blue". The goal is then to reduce the "Blue" component and to keep the "Red" and "Green" ones unchanged. The following matrix can be used for a reduction by a half of the blue component. Figure 13-65 gives the corresponding matrix and equations for each component.

Figure 13-65. Example - Diagonal Matrix Configuration

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \left(\begin{bmatrix} 256 & 0 & 0 \\ 0 & 256 & 0 \\ 0 & 0 & 128 \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix} \right)$$

$$\longrightarrow Rout = \frac{1}{256} * \left(256 * Rin \right) \Rightarrow Rout = Rin$$

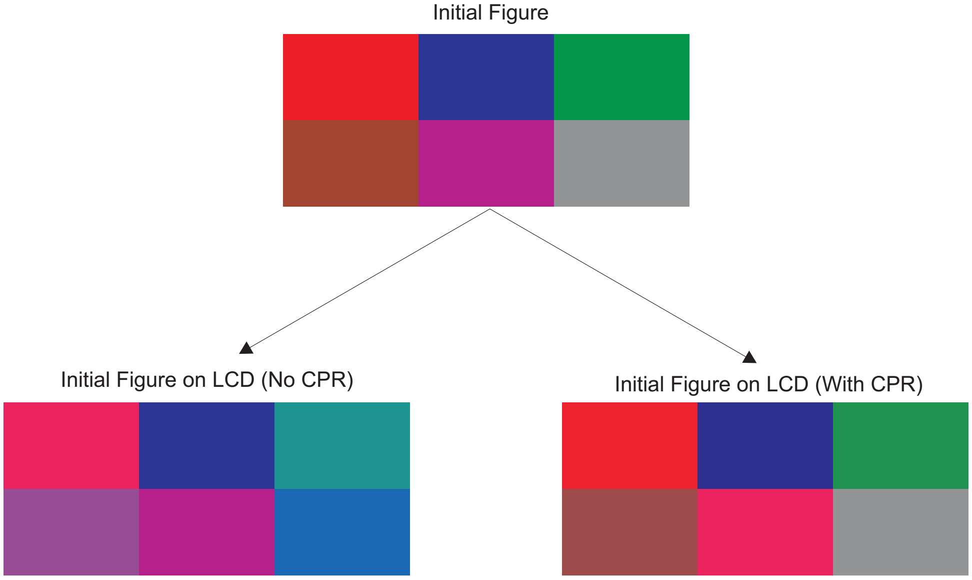
$$\longrightarrow Gout = \frac{1}{256} * \left(256 * Gin \right) \Rightarrow Gout = Gin$$

$$\longrightarrow Bout = \frac{1}{256} * \left(128 * Bin \right) \Rightarrow Bout = 0.5 * Bin$$

dss-201

Figure 13-66 shows the result of an image on a "blue" backlight screen with and without CPR.

Figure 13-66. Image With and Without CPR (Diagonal Matrix)



dss-202

A drawback of this diagonal matric is that the color reduction is linear. The contrast is then different from the initial image. It is then necessary to use the 6 other coefficients of the CPR matrix to better correct a non-white backlight. The goal is to find the correct coefficients that remove the color offset added by the non-white backlight.

13.4.3.4.6.2 Color Phase Rotation - Standard Matrix

In the following example, the LCD backlight adds an offset of 128 (B_offset) to the Blue component. Figure 13-67 shows an example of matrix that reduces the offset of the screen, the corresponding equations and the resulting output colors.

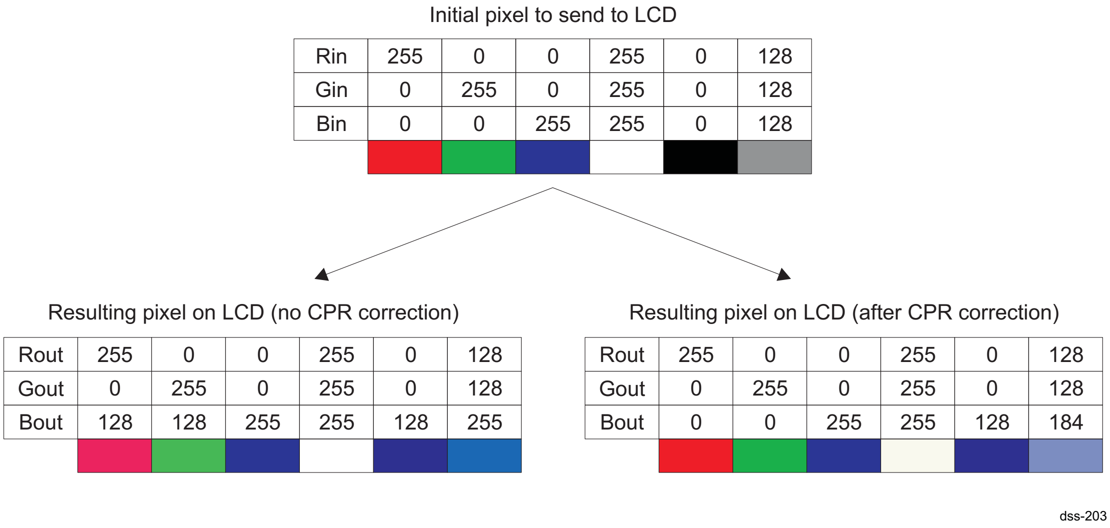
Figure 13-67. Example - Image With and Without CPR (Standard Matrix)

$$\begin{bmatrix} Rout \\ Gout \\ Bout \end{bmatrix} = \frac{1}{256} * \left(\begin{bmatrix} 256 & 0 & 0 \\ 0 & 256 & 0 \\ -129 & -129 & 370 \end{bmatrix} * \begin{bmatrix} Rin \\ Gin \\ Bin \end{bmatrix} \right)$$

$$\rightarrow \quad Rout = \frac{1}{256} * \left(256 * Rin \right)$$

$$\rightarrow \quad Gout = \frac{1}{256} * \left(256 * Gin \right)$$

$$\rightarrow \quad Bout = \frac{1}{256} * \left(-129 * Rin + -129 * Gin + 370 * Bin \right) + B\_offset$$



Initial pixel to send to LCD

Rin	255	0	0	255	0	128
Gin	0	255	0	255	0	128
Bin	0	0	255	255	0	128

Resulting pixel on LCD (no CPR correction)

Rout	255	0	0	255	0	128
Gout	0	255	0	255	0	128
Bout	128	128	255	255	128	255

Resulting pixel on LCD (after CPR correction)

Rout	255	0	0	255	0	128
Gout	0	255	0	255	0	128
Bout	0	0	255	255	128	184

This CPR matrix gives inputs and outputs very close. However, black cannot be corrected because of it's zero-components. No matter which coefficients are used in the matrix, the result will always be equal to the offset added by the LCD backlight.

13.4.3.5 TV Set-Specific Control Registers

The following registers define the digital output configuration:

- DSS.DISPC_CTRL
- DSS.DISPC_CFG
- DSS.DISPC_DEFAULT_COLOR_m (m=1)
- DSS.DISPC_TRANS_COLOR_m (m=1)
- DSS.DISPC_SIZE_DIG

The digital output is enabled/disabled by setting/resetting the DSS.DISPC_CTRL[1] DIGITAL_EN bit. A valid configuration must be set before the digital output can be enabled.

Perform the initialization sequence as follows:

1. Initialize the video encoder and the display controller configuration registers.
2. Set the DSS.DISPC_CTRL[6] GO_DIGITAL bit and the DSS.DISPC_CTRL[1] DIGITAL_EN bit to 1.
3. Wait for the first VSYNC pulse signal.
4. Clear the SYNC_LOST_DIGITAL interrupt by setting the DSS.DISPC_IRQSTS[15] SYNC_LOST_DIGITAL bit to 1.
5. Enable the SYNC_LOST_DIGITAL interrupt by setting the DSS.DISPC_IRQEN[15] SYNC_LOST_DIGITAL bit to 1.

13.4.3.5.1 Digital Timings

The following bit fields define the timing information:

- Data hold time (the DSS.DISPC_CTRL[19:17] HT bit field)
- Logic clock divisor (the DSS.DISPC_DIVISOR[23:16] LCD bit field)

The 8-bit pixel clock divider (DSS.DISPC_DIVISOR[23:16]) bit field is used to select the logic clock frequency. The LCD generates a range of pixel clock frequencies from FCK/1 to FCK/255, where FCK is the input functional clock of the display controller.

13.4.3.5.2 Digital Frame/Field Size

The following bit fields define the field size (frame if progressive mode):

- Number of lines per panel (the DSS.DISPC_SIZE_DIG[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC_SIZE_DIG[10:0] PPL bit field)

13.4.3.5.3 Digital Overlay

The following bit fields define the overlay attributes of the digital output:

- Transparency color key (the DSS.DISPC_TRANS_COLOR_m register (m=1))
- Transparency color key enable (the DSS.DISPC_CFG[12] TCK_DIG_EN bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.DISPC_CFG[13] TCK_DIG_SELECTION bit)
- The default solid background color is defined in the DSS.DISPC_DEFAULT_COLOR_m[23:0] DEFAULT_COLOR bit field (i=1).
- Alpha blender Enable (DSS.DISPC_CFG[19] TV_ALPHA_BLDR_EN)
- Global alpha blending values (DSS.DISPC_GLOBAL_ALPHA[23:16] VID2_GLOBAL_ALPHA and DSS.DISPC_GLOBAL_ALPHA[7:0] GFX_GLOBAL_ALPHA). The value 0xFF corresponds to 100% opaque and 0 to 100% transparent

NOTE: The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

NOTE: When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

When this bit field is set to the appropriate values, set the DSS.DISPC_CTRL[6] GO_DIGITAL bit to indicate that all shadow registers of the pipelines connected to the digital output are latched by the hardware (only if the DSS.DISPC_CTRL[1] DIGITAL_EN bit is already set to 1). If the digital output is disabled, the new values will be updated when the DSS.DISPC_CTRL[1] DIGITAL_EN bit will be set to 1.

13.4.4 RFBI Basic Programming Model

The RFBI programming model must be used for LCD display support only.

13.4.4.1 DISPC Control Registers

The following DISPC registers are used in RFBI mode:

- The STALL mode is selected by setting the DSS.DISPC_CTRL[11] STALL_MODE bit. The DSS.DISPC_CTRL[5] GO_LCD bit must not be set to 1, but the display controller configuration (DMA engine, pipelines associated to the LCD output,..) must be set before enabling the LCD output by setting the DSS.DISPC_CTRL[0] LCD_EN bit to 1.
- To enable the hardware handcheck to avoid underflow, the DSS.DISPC_CFG[16] FIFO_HAND_CHECK must be set to 1. The reset value of this bit is 0. The handcheck applies to the pipelines connected to the LCD output. It must be disabled before resetting the DSS.DISPC_CTRL[11]

STALL_MODE bit to 0. The new setting for the FIFO handcheck is used for the following frames.

NOTE: The LCD output is disabled at the end of the transfer of the frame. The software must reenable the LCD output to generate a new frame by setting the DSS.DISPC_CTRL[0] LCD_EN to 1. See Figure 13-68.

13.4.4.2 RFBI Control Registers

The following registers define the RFBI control registers:

- DSS.RFBI_CTRL
- DSS.RFBI_PIXEL_CNT
- DSS.RFBI_LINE_NUMBER

13.4.4.2.1 High Threshold

The DSS.RFBI_CTRL[6:5] HIGH_THR bit field is used to define the threshold to be used for the generation of the DMA request to receive data into the interconnect FIFO (24 x 32 FIFO depth) through the address of the register RFBI_DATA. It must be the size of the burst. The supported values are 4x32, 8x32 and 16x32. The system DMA receives the DMA request and is in charge of providing the correct number of bytes. If the DSS.RFBI_CTRL[7] DISABLE_DMA_REQ bit is reset, the DMA request is generated when there is enough room in the interconnect FIFO to accept the full burst. In case the RFBI receives writes L4 requests to the RFBI_DATA location when the interconnect FIFO is full, the request is not accepted. The RFBI waits for a free entry in the interconnect FIFO to accept the L4 request.

If the DSS.RFBI_CTRL[7] DISABLE_DMA_REQ bit is set, the DMA request is not generated. The threshold value is ignored.

NOTE: Software users can access the RFBI_DATA location without using the DMA request and without programming the high threshold value (backward mode).

13.4.4.2.2 Bypass Mode

Setting the DSS.RFBI_CTRL[1] BYPASS_MODE bit directly outputs the LCD controller output to the LCD panel. Resetting this bit directs the MPU module to send commands/parameters and data from the input video port FIFO.

13.4.4.2.3 Enable

Setting/resetting the DSS.RFBI_CTRL[0] EN bit enables/disables the RFBI module. The hardware resets the enable bit after all of the pixels are sent to the panel. The DSS.RFBI_PIXEL_CNT[31:0] PIXEL_CNT bit field value defines the number of pixels to send to the LCD panel. When the transfer is finished, the configuration used can be modified.

Table 13-29. RFBI Behavior

RFBI_CTRL[1] BYPASS_MODE bit value	RFBI_CTRL[0] ENABLE bit value	RFBI Behavior
0	0	L4 interconnect can write command/param/data and read data/status from the Remote Frame Buffer (RFB). L4 interconnect access can only be done to the CSx actually active
0	1	The DISPC sends pixels to the RFB.

The stall signal is asserted when the module is disabled. Through the L4 port, pixels can be sent to the LCD panel only when the pixel count has reach the value 0x0

NOTE: The LCD output is disabled at the end of the transfer of the frame. The software must reenable the LCD output to generate a new frame by setting the DSS.DISPC_CTRL[0] LCD_EN to 1. See Figure 13-68.

13.4.4.2.4 Configuration Selection

Setting the DSS.RFBI_CTRL[3:2] CONFIG_SELECT bit field selects the configuration number (1 or 0 if bits are set or reset). The registers associated with the configuration output the data to the LCD panel.

If both chip-selects are selected, the configuration for the first chip-select is used (except for the polarity of the RFBI_CS1 signal defined by the second configuration) and both devices connected to the CS signals are driven in parallel. In read mode, if both chip-selects are set, only RFBI_CS0 is asserted to read data from the device connected on RFBI_CS0. In write mode with two chip-selects selected, the RFBI can write to the two devices simultaneously.

13.4.4.2.5 ITE Bit

Set the DSS.RFBI_CTRL[4] ITE bit to start capturing the data from the display controller. This bit has no effect if the trigger mode is set to external. The display controller must be configured in the STALL mode to account for the RFBI_DISPC_STALL signal. Setting the trigger mode to external (DSS.RFBI_CONFIG_i[3:2] TRIGGER_MODE bit field set to 0x1 or 0x2) causes the DSS.RFBI_CTRL[4] ITE bit to be ignored. The corresponding chip-select must be selected when this bit is set by users.

The RFBI_DISPC_STALL signal is asserted when at least one of the following cases occur:

- Default status when no data to capture from the display controller
- High FIFO threshold reached
- End of the transfer (number of data to output)
- Reset of the RFBI module
- DSS.RFBI_CTRL[0] EN bit reset to 0x0

The RFBI_DISPC_STALL signal is deasserted when the DSS.RFBI_CTRL[0] EN bit is set to 0x1 and at least one of the following cases occur:

- Low FIFO threshold reached
- External TE occurs and the DSS.RFBI_CONFIG_i[3:2] TRIGGER_MODE bit field is set to 0x1 or 0x2 for automatic external trigger (start of the transfer, the FIFO pointers are reset, the FIFO is empty).
- DSS.RFBI_CTRL[4] ITE bit set to 0x1 by users (start of the transfer, the FIFO pointers are reset, the FIFO is empty).

13.4.4.2.6 Number of Pixels to Transfer

Setting the DSS.RFBI_PIXEL_CNT[31:0] PIXEL_CNT bit field value directs the application to indicate the number of pixels to be transferred to the LCD panel. The value can be changed only when the DSS.RFBI_CTRL[0] EN is reset.

During the transfer, the hardware decrements the register when a pixel is sent to the remote frame buffer. When the DSS.RFBI_CTRL[0] EN bit is set and a new value is written in the DSS.RFBI_PIXEL_CNT register when the current value in the register is a non-zero (the remaining number of pixels to transfer), the ongoing transfer is aborted.

From the L4 interconnect side, if the DSS.RFBI_CONFIG_i[10:9] CYCLE_FMT bit field is equal to 0x3 and the DSS.RFBI_CONFIG_i[8:7] L4_FMT bit field is equal to 0x0, an even number of write accesses to the data register must be performed before accessing any other register (CMD/PARAM/STATUS/READ).

When the DSS.RFBI_CONFIG_i[10:9] CYCLE_FMT bit field is 0x3 (2 pixels are sent over 3 cycles), the number of pixels to be programmed in the DSS.RFBI_PIXEL_CNT[31:0] PIXEL_CNT bit field must be a multiple of 2. If another CYCLE_FMT is used, the value for PIXEL_CNT can be odd or even. This constraint is valid for data provided on the L4 interconnect port and from the display controller.

If the DSS.RFBI_CONFIG_i[10:9] CYCLE_FMT bit field is equal to 0x3, the DSS.RFBI_CONFIG_i[8:7] L4_FMT bit field is equal to 0, and back-to-back register write is processed. The following registers should be written after the first data: RFBI_CMD, RFBI_PARAM, RFBI_READ, and RFBI_STS. The whole data transfer must first be performed before being able to write to any other registers (RFBI_CMD, RFBI_PARAM, RFBI_READ, and RFBI_STS).

13.4.4.2.7 Programmable Line Number

When the trigger mode is set to external trigger mode with HSYNC and VSYNC or the TE, hardware resets the line counter when the VSYNC occurs and, after a programmable number of lines (the HSYNC pulse occurs for every line), the transfer to the LCD panel begins. When the programmable line number is 0, only the VSYNC pulse indicates the beginning of the transfer in both modes: HSYNC/VSYNC and TE (logical OR operation between HSYNC and VSYNC).

13.4.4.3 RFBI Configuration

The following registers define the RFBI configuration:

- DSS.RFBI_SYSCONFIG
- DSS.RFBI_SYSSTS
- DSS.RFBI_CONFIG_0 (configuration 0) and DSS.RFBI_CONFIG_1 (configuration 1)
- DSS.RFBI_VSYNC_WIDTH
- DSS.RFBI_HSYNC_WIDTH

The configuration register for one configuration can be accessed only when the configuration is not in use (based on the value of the RFBI_CTRL[3:2] CONFIG_SELECT bit field).

13.4.4.3.1 Parallel Mode

The DSS.RFBI_CONFIG_i[1:0] PARALLEL_MODE bit field (where i = 0, 1) defines the width of the interface (8-, 9-, 12-, or 16-bit parallel).

13.4.4.3.2 Trigger Mode

Setting the DSS.RFBI_CONFIG_i[3:2] TRIGGER_MODE bit field configures the trigger on the external TE signal (RFBI_TE_VSYNC), or external with VSYNC/HSYNC with the programmable number of HSYNCs to begin the transfer in both cases or the internal programmable DSS.RFBI_CTRL[4] ITE bit.

13.4.4.3.3 VSYNC Pulse Width (Minimum Value)

The DSS.RFBI_VSYNC_WIDTH[15:0] MIN_VSYNC_PULSE_WIDTH bit field defines the minimum number of L4 clock cycles of the VSYNC pulse for detection on VSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal and is also used in the VSYNC/HSYNC mode on the two separate input lines.

- The VSYNC pulse width must be at least equal to two L4 cycles when HSYNC is not present.
- The VSYNC pulse width must be at least equal to four L4 cycles when HSYNC is present.

13.4.4.3.4 HSYNC Pulse Width (Minimum Value)

The DSS.RFBI_HSYNC_WIDTH[15:0] MIN_HSYNC_PULSE_WIDTH bit field defines the minimum number of L4 clock cycles of the HSYNC pulse for detection on HSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal, and is also used in the VSYNC/HSYNC mode on the separate two input lines. The HSYNC pulse width must always be at least equal to two L4 cycles to be detected.

13.4.4.3.5 Cycle Format

Setting the DSS.RFBI_CONFIG_i[10:9] CYCLE_FMT bit field (with i = 0, 1) defines which registers are used to format the data in the interconnect FIFO with the appropriate number of bits (starting from the LSB) and with the alignment on the interface as follows:

- DSS.RFBI_DATA_CYCLE_i (if DSS.RFBI_CONFIG_i[10:9] CYCLE_FMT bit field = 00) only

  or

- DSS.RFBI_DATA_CYCLE1_i and DSS.RFBI_DATA_CYCLE2_i (if DSS.RFBI_CONFIG_i[10:9] CYCLE_FMT bit field = 01)

  or

- DSS.RFBI_DATA_CYCLE1_i, DSS.RFBI_DATA_CYCLE2_i, and DSS.RFBI_DATA_CYCLE3_i (if DSS.RFBI_CONFIG_i[10:9] CYCLE_FMT bit field = 10)

The data from the display controller and from the L4 interconnect are formatted based on the configuration of the DSS.RFBI_DATA_CYCLE_i registers.

13.4.4.3.6 Unused Bits

Based on the configuration, the undefined bits for each cycle are defined with the previous values of the bits at the same position in the previous cycle, 0s, or 1s (the unused bits can be at any position). The DSS.RFBI_CONFIG_i[12:11] UNUSEDBITS bit field (with i = 0, 1) is used.

13.4.4.3.7 RFBI Timings

The timing registers for one configuration can be accessed only when the configuration is not in use (based on the value of the DSS.RFBI_CTRL[3:2] CONFIG_SELECT bit field). Granularity is defined using the DSS.RFBI_CONFIG_i[4] TIME_GRANULARITY bit. This feature allows the extension of programmable ranges of timing parameters for the RFBI interface. Refer to Table 13-30 for the bits configuration values.

- Chip-select assertion/deassertion time

  RFBI_A0 setup time to chip-select assertion is assured by the programmable chip-select assertion time from the start access time:
  DSS.RFBI_ONOFF_TIMEi[3:0] CS_ONTIME bit field (with i = 0, 1).

  The chip-select deassertion time from the start access time is programmable:
  DSS.RFBI_ONOFF_TIMEi[9:4] CS_OFFTIME bit field (with i = 0, 1)

CAUTION

Configuring DSS.RFBI_ONOFF_TIMEi[3:0] CS_ONTIME = DSS.RFBI_ONOFF_TIMEi[9:4] CS_OFFTIME = 0 (with i = 0, 1) is not supported and must be avoided. This configuration creates contention on the bus and progressively damages the LCD panel.

- Chip-select pulse width

  The total chip-select pulse width is the time when write cycle time or read cycle time has completed and is programmable:
  DSS.RFBI_CYCLE_TIMEi[17:12] CS_PULSE_WIDTH bit field (with i = 0, 1)

  It applies on the read-to-write, write-to-read, read-to-read, and write-to-write access based on:

  - The DSS.RFBI_CYCLE_TIMEi[19] RR_EN bit: Read-to-read access
  - The DSS.RFBI_CYCLE_TIMEi[20] WW_EN bit: Write-to-write access
  - The DSS.RFBI_CYCLE_TIMEi[18] RW_EN bit: Read-to-write access
  - The DSS.RFBI_CYCLE_TIMEi[21] WR_EN bit: Write-to-read access

  By default, it applies to any access (read-to-read, read-to-write, write-to-read, write-to-write) when the chip-select changes.

- Access time

The total access time is the time from when A0 becomes valid until data are sampled before deasserting the RE signal; access time is programmable:
DSS.RFBI_CYCLE_TIMEi[27:22] ACCESS_TIME bit field (with i = 0, 1)

When reading the data on the bus, the data are sampled at the end of the access time, which occurs before the end of the read off time (DSS.RFBI_ONOFF_TIMEi[29:24] RE_OFFTIME, with i = 0, 1).

- Write enable cycle time

  The total write enable cycle time is the time from when A0 becomes valid until write cycle completion; the write enable cycle time is programmable:
  The DSS.RFBI_CYCLE_TIMEi[5:0] WE_CYCLE_TIME bit field (with i = 0, 1)
- Write enable assertion/deassertion time

  The WE assertion delay time from start access time is programmable:
  DSS.RFBI_ONOFF_TIMEi[13:10] WE_ONTIME bit field (with i = 0, 1)

  The WE deassertion delay time from the start access time is programmable:
  DSS.RFBI_ONOFF_TIMEi[19:14] WE_OFFTIME bit field (with i = 0, 1)
- Read enable cycle

  The total read enable cycle time is the time when A0 becomes valid until read cycle completion; the read enable cycle time is programmable:
  The DSS.RFBI_CYCLE_TIMEi[11:6] RECYCLE_TIME bit field (with i = 0, 1)
- Read enable assertion/deassertion time

  The RE assertion delay time from the start access time is programmable:
  DSS.RFBI_ONOFF_TIMEi[23:20] RE_ONTIME bit field (with i = 0, 1)

  The RE deassertion delay time from the start access time is programmable:
  DSS.RFBI_ONOFF_TIMEi[29:24] RE_OFFTIME bit field (with i = 0, 1)

At cycle time completion (read access or write access) all control signals (RFBI_CSi, RFBI_WR, and RFBI_RD, with i = 0, 1) are deasserted regardless of their deassertion time parameter values, if they are not deasserted already.

However, an exception to this forced deassertion exists when a pipelined request to the same chip-select or to a different chip-select is pending. Also, a control signal with deassertion time parameters equal to the cycle time parameter is not necessarily deasserted when a pipelined request to the same chip-select or different chip-select is pending. This prevents any unnecessary glitch transitions.

If no inactive cycles are required between successive accesses to the same chip-select (the DSS.RFBI_CYCLE_TIMEi[17:12] CS_PULSE_WIDTH bit field = 0, with i = 0, 1), and if assertion time parameters associated with the following access equal 0, the asserted control signals (RFBI_CSi, RFBI_WR, and RFBI_RD, with i = 0, 1) stay asserted. This is applicable to any read/write-to-read/write access combination.

Table 13-30 summarizes the configurations values for each timing bit.

Table 13-30. RFBI Timings Configuration

Configuration bits[1]	Granularity[2]	
	one	two
DSS.RFBI_ONOFF_TIMEi[3:0] CS_ONTIME	0 to 15	0 to 30
DSS.RFBI_ONOFF_TIMEi[9:4] CS_OFFTIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIMEi[17:12] CS_PULSE_WIDTH	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIMEi[27:22] ACCESS_TIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIMEi[5:0] WE_CYCLE_TIME	0 to 63	0 to 126
DSS.RFBI_ONOFF_TIMEi[13:10] WE_ONTIME	0 to 15	0 to 30
DSS.RFBI_ONOFF_TIMEi[19:14] WE_OFFTIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIMEi[11:6] RECYCLE_TIME	0 to 63	0 to 126
DSS.RFBI_ONOFF_TIMEi[23:20] RE_ONTIME	0 to 15	0 to 30

[1] Where i = 0 or 1.

[2] Number of L4Clk cycles. The granularity can be configured using the DSS.RFBI_CONFIG_i[4] TIME_GRANULARITY bit.

Table 13-30. RFBI Timings Configuration (continued)

Configuration bits[1]	Granularity[2]	
	one	two
DSS.RFBI_ONOFF_TIMEi[29:24] RE_OFFTIME	0 to 63	0 to 126

13.4.4.3.8 RFBI State-Machine

Referring to Table 13-18, the signals RFBI_A0, RFBI_RD, and RFBI_WR are asserted/deasserted based on the register accessed (DSS.RFBI_CMD, DSS.RFBI_PARAM, DSS.RFBI_DATA, DSS.RFBI_READ, and DSS.RFBI_STS). When the DSS.RFBI_SYSSTS[8] BUSY bit is set by hardware, any access to the registers is stalled, except for the RFBI_DATA register.

The DSS.RFBI_SYSSTS[9] BUSY_RFBI_DATA bit indicates whether there are still pending data in the interconnect FIFO associated with the register RFBI_DATA only.

- Command register

  Write a command at a time by writing in the DSS.RFBI_CMD register. If the previous command is not processed, the DSS.RFBI_SYSSTS[8] BUSY bit is set by hardware and the access to writing a new command is stalled.

- Parameter register

  Write a parameter at a time by writing in the DSS.RFBI_PARAM register.

  If the previous parameter is not processed, the DSS.RFBI_SYSSTS[8] BUSY bit is set by hardware and the access to writing a new parameter is stalled.

- Data register

  Write one or two pixels at a time by writing in the RFBI_DATA register (when DSS.RFBI_CONFIG_i[10:9] CYCLE_FMT = 0x3 with i = 0, 1, two pixels must be written contiguously, no other access to RFBI registers except DSS.RFBI_DATA is allowed).

  The pixels are formatted based on the specified cycle format. If two pixels are written into the 32-data register, the DSS.RFBI_CONFIG_i[8:7] L4_FMT bit field indicates the number of pixels for each L4 access to the register and the order of the pixels

  If the previous data are not processed, the DSS.RFBI_SYSSTS[8] BUSY bit is set by hardware and any access for writing new data is stalled. When the DSS.RFBI_SYSSTS[8] BUSY bit is reset by hardware, the access is not stalled.

- Read/status register

  Send through the command and parameter registers the correct information to receive data in the data or status register. The read data from the LCD panel is initiated by writing into the DSS.RFBI_READ or DSS.RFBI_STS registers. In this case, the DSS.RFBI_SYSSTS[8] BUSY bit is set until the data are available in the register.

  When the DSS.RFBI_SYSSTS[8] BUSY bit is set by hardware, the read or write access is stalled until the register is updated with a new value from the LCD panel. To avoid the stall, the software can poll the DSS.RFBI_SYSSTS[8] BUSY bit until it is reset by hardware. To receive the data, send the appropriate command/parameters.

13.4.4.3.9 RFBI Configuration Flow Charts

The RFBI configuration depends on the trigger mode used by the application. The available trigger modes are:

- Internal trigger mode when setting the DSS.RFBI_CONFIG_i[3:2] TRIGGER_MODE bit field to 0x0
- External trigger mode:
  - TE external trigger mode when setting the DSS.RFBI_CONFIG_i[3:2] TRIGGER_MODE bit field to 0x1
  - HSYNC/VSYNC external trigger mode when setting the DSS.RFBI_CONFIG_i[3:2] TRIGGER_MODE bit field to 0x2

Figure 13-68 gives an example of how to program and use the RFBI module:

Figure 13-68. How to Use RFBI

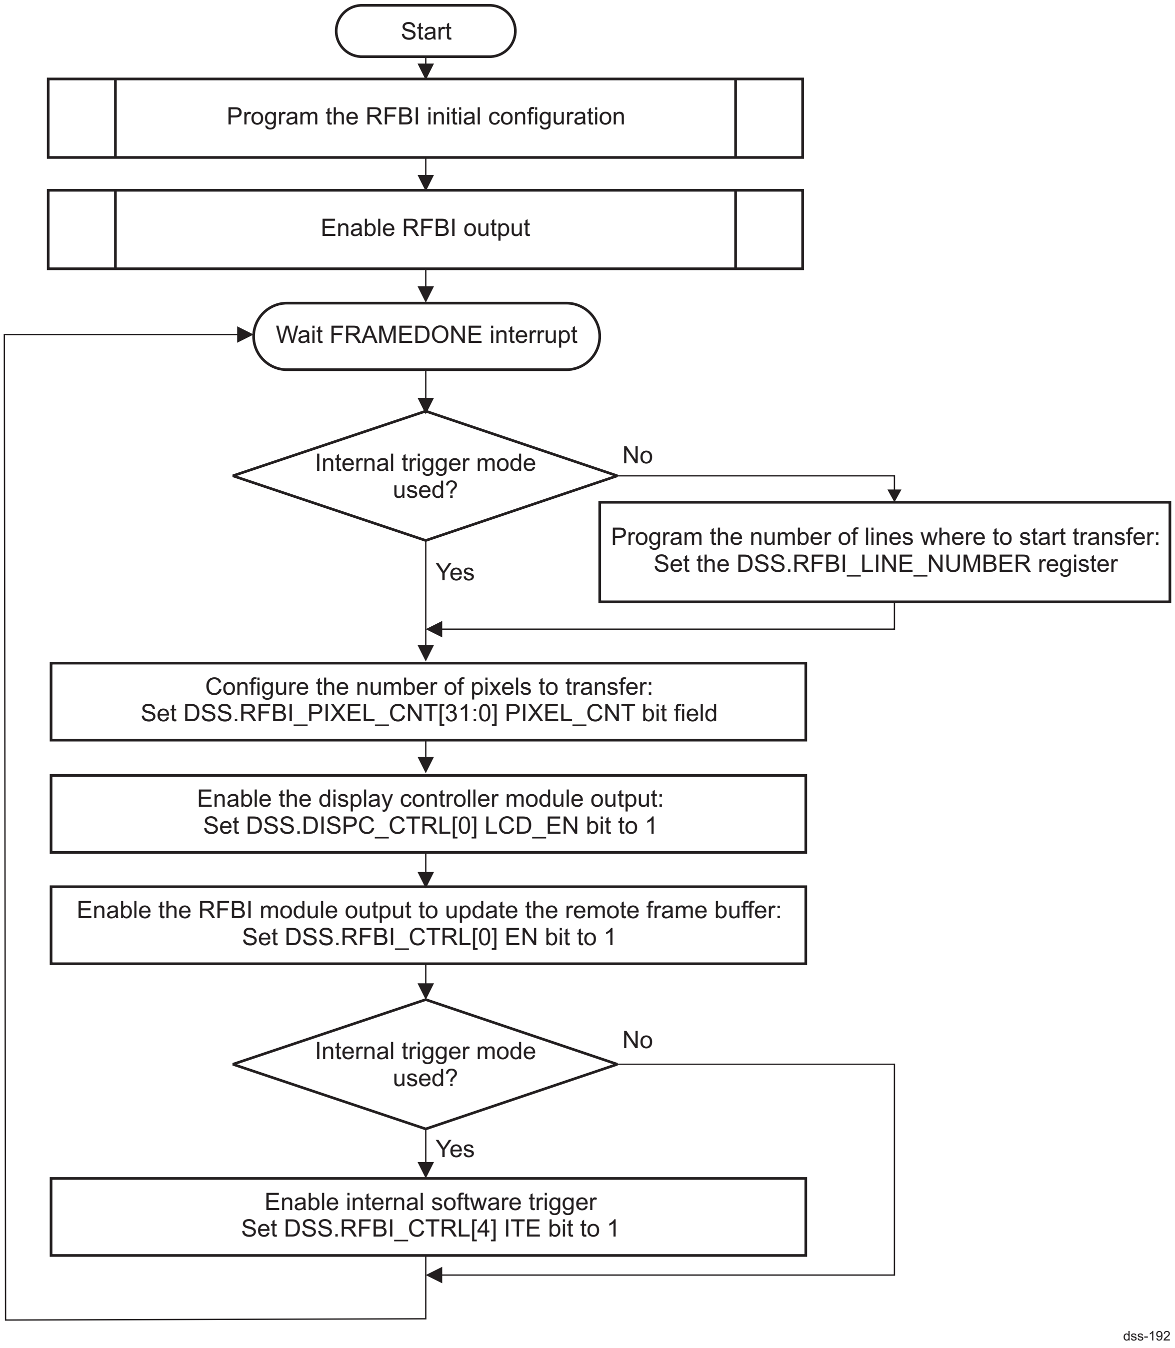


Figure 13-69 details how to configure the RFBI registers:

Figure 13-69. RFBI Initial Configuration

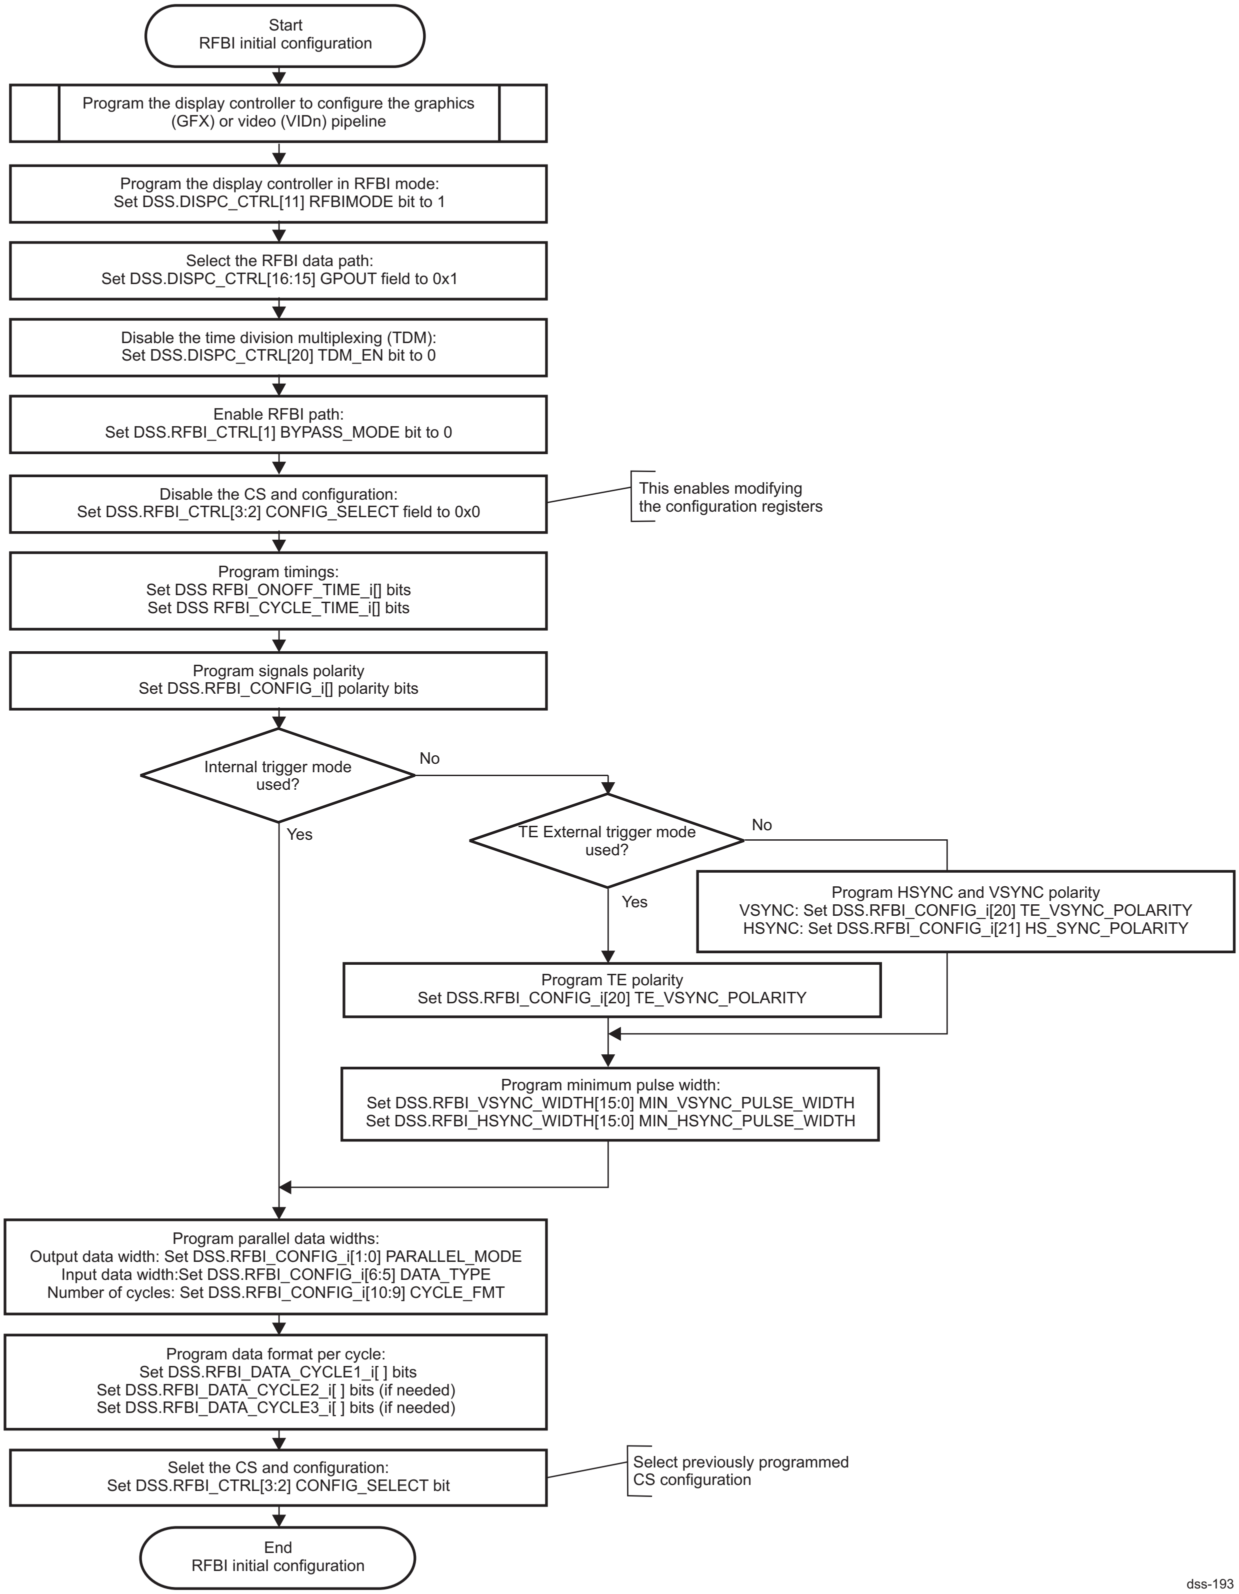

Figure 13-70 describes how to enable the RFBI module.

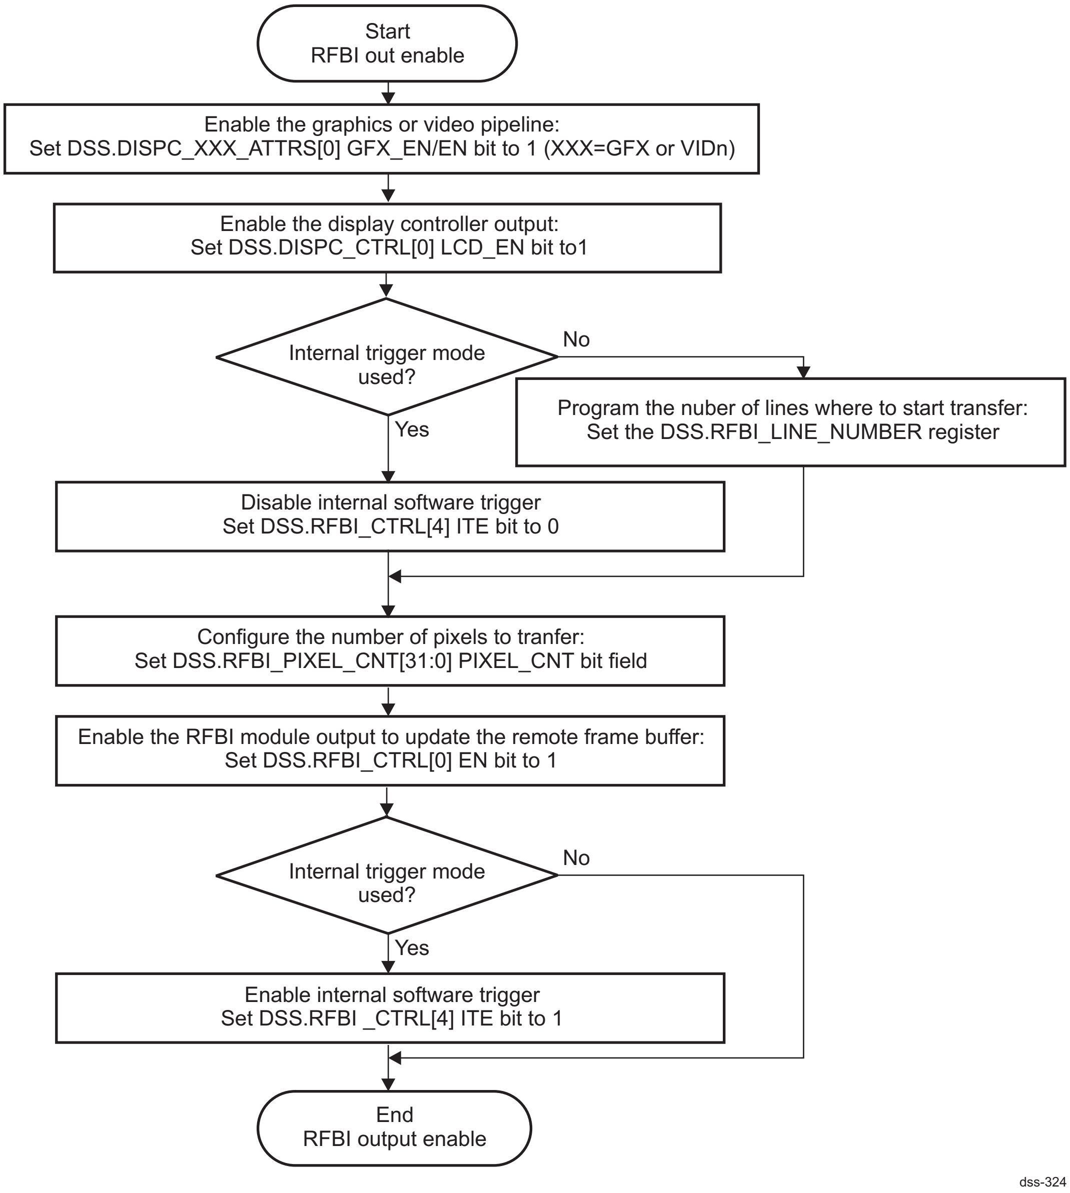
Figure 13-70. RFBI Output Enable



13.5 Use Cases

This section gives some generic use cases and tips for setting the modules of the display subsystem.

13.5.1 How to Configure the Scaling Unit in the DISPC Module

This section describes the scaling capability of the display controller (DISPC). The scaling unit is a part of the video pipeline is used when transferring pixels from the system memory (SDRAM or on-chip SRAM) to the LCD panel or the TV set. The scaling unit consists of two scaling blocks: The vertical scaling block followed by the horizontal scaling block. The input pixel format is RGB24. In case the pixel format in system memory is not RGB, the color space conversion unit in front of the scaling unit converts the YUV pixels into RGB pixels. The two scaling units are independent: Neither of them, only one, or both can be used simultaneously

13.5.1.1 Filtering

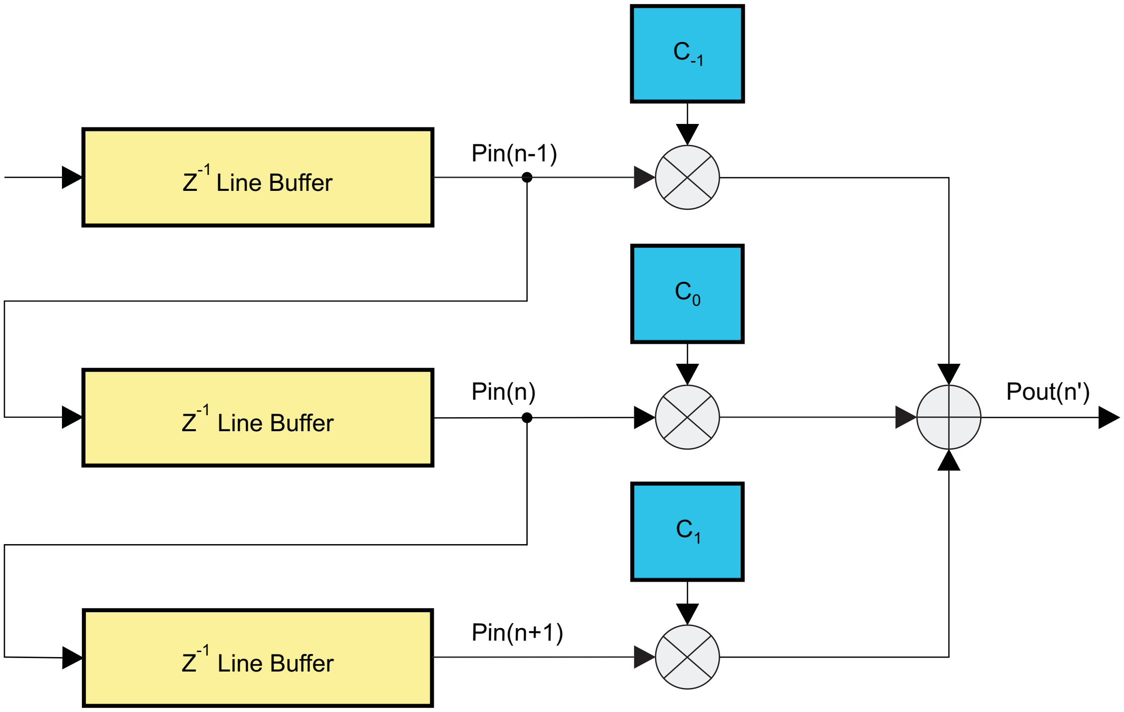
The scaling is used to down-scale, up-scale, or process the image while keeping the same size. It is applied independently horizontally and vertically. The same filtering applies for each color component (R, G, or B).

13.5.1.1.1 Vertical Filtering

The vertical filtering unit is based on a poly-phase rotation architecture with eight phases and three taps. That means that 24 coefficients are programmable

The vertical 3-tap filtering macro architecture is shown in Figure 13-71.

Figure 13-71. Vertical Filtering Macro Architecture (Three Taps)



dss-112

For the 3-tap vertical up/downsampling the equation is (with the example of R component):

$$Rout(n) = \left(\sum_{i=-1}^{i=1} Ci(\Phi) \times Rin(n+i) \right) >> 7 \tag{12}$$

dss-E067

Legend:

Rout: R component output

Ci():Vertical FIR coefficients

Rin: R component input

The line (n+1) is older than line (n).

NOTE: If the 5-tap resizer is used for RGB16 and YUV4:2:2 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels. This leads to the following register configuration:

DISPC_VIDn_ATTRS[21] VERTICAL_TAPS == 1

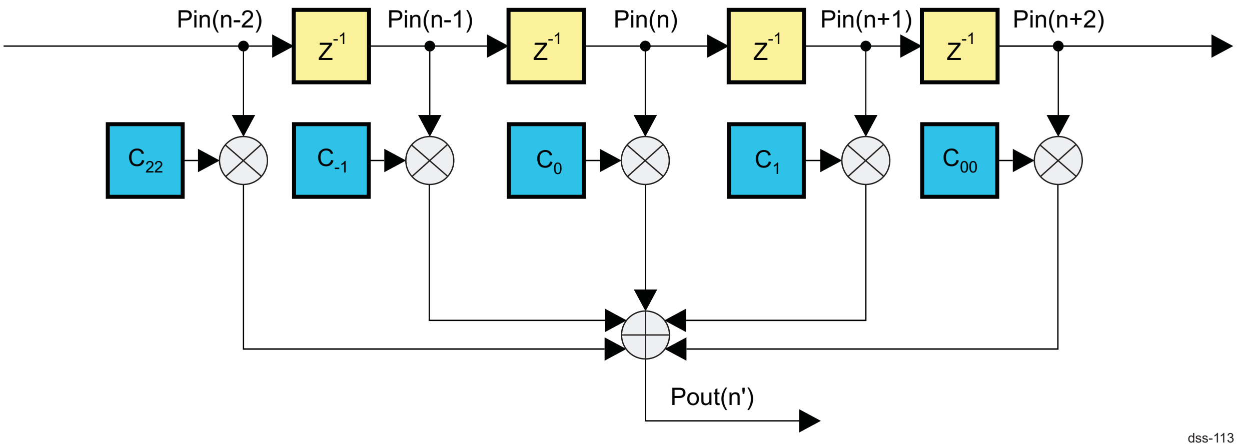
DISPC_VIDn_PICTURE_SIZE[10:0] VID_ORG_SIZE_X 4 and even

The programmable three coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient $C_0()$, which is unsigned).

The vertical filtering unit can be configured to support five taps.

The vertical 5-tap filtering macro architecture is shown in Figure 13-72.

Figure 13-72. Vertical Filtering Macro Architecture (Five Taps)



For the 5-tap vertical up/downsampling the equation is (with the example of R component):

$$Rout(n) = \left(\sum_{i=-2}^{i=2} Ci(\Phi) \times Rin(n+i) \right) >> 7 \qquad (13)$$

dss-E066

Legend:

Rout: R component output

Ci():Vertical FIR coefficients with $C_{+2}()=C_{00}()$ and $C_{-2}()=C_{22}()$

Rin: R component input

The line (n+1) is older than line (n).

The programmable five coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C0(), which is unsigned).

In case of three taps, the memory lines are merged into three lines instead of six lines (one line is used as a cache line).

The first line is duplicated to fill up the two first lines (3-tap configuration) and the three first lines (5-tap configuration).

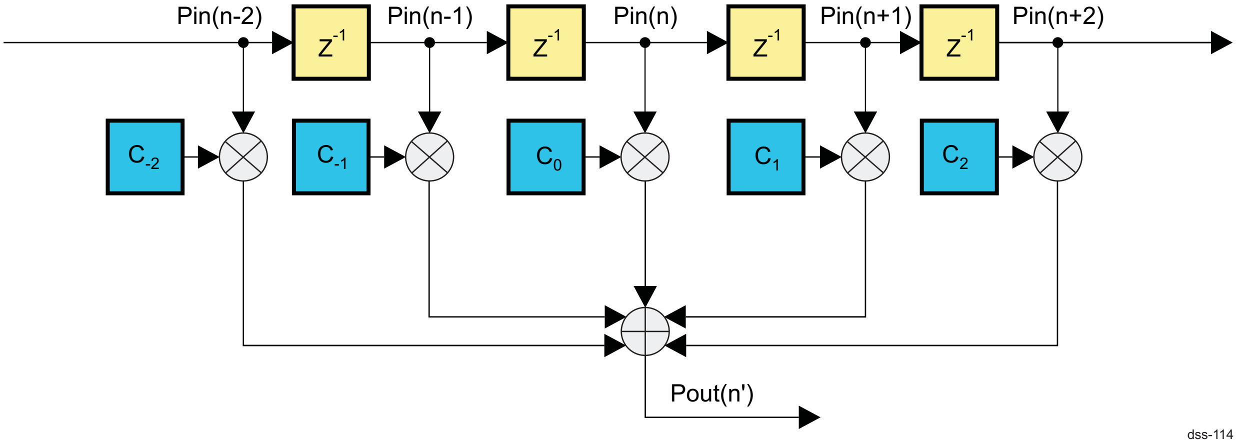
The last line is duplicated if the scaling logic requires loading of more lines and the last line has been reached

13.5.1.1.2 Horizontal Filtering

The horizontal filtering unit is based on a poly-phase rotation architecture with eight phases and five taps. That means that 40 coefficients are programmable.

The horizontal filtering macro architecture is shown in Figure 13-73.

Figure 13-73. Horizontal Filtering Macro Architecture (Five Taps)



For the 5-tap horizontal up/downsampling, the equation is (with the example of R component):

$$\mathrm{Rout}(n) = \left(\sum_{i=-3}^{i=3} Ci(\Phi) \times \mathrm{Rin}(n+i) \right) >> 7 \tag{14}$$

dss-E115

Legend:

Rout: R component output

Ci():Vertical FIR coefficients

Rin: R component input

The line (n+1) is older than line (n).

To horizontally and vertically filter the video layer, the phase is calculated separately. The programmable coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C_0(), which is unsigned).

The first pixel is duplicated to fill up the three first pixel-buffers (5-tap configuration). The last pixel is duplicated if the scaling logic requires loading of more pixels and the last pixel has been reached

13.5.1.2 Scaling Algorithms

The up/downsampling finite state machines (FSM) below are detailed in this section.

Figure 13-74 presents the vertical up/downsampling FSM.

Figure 13-74. Vertical Up-/Down-Sampling Algorithm

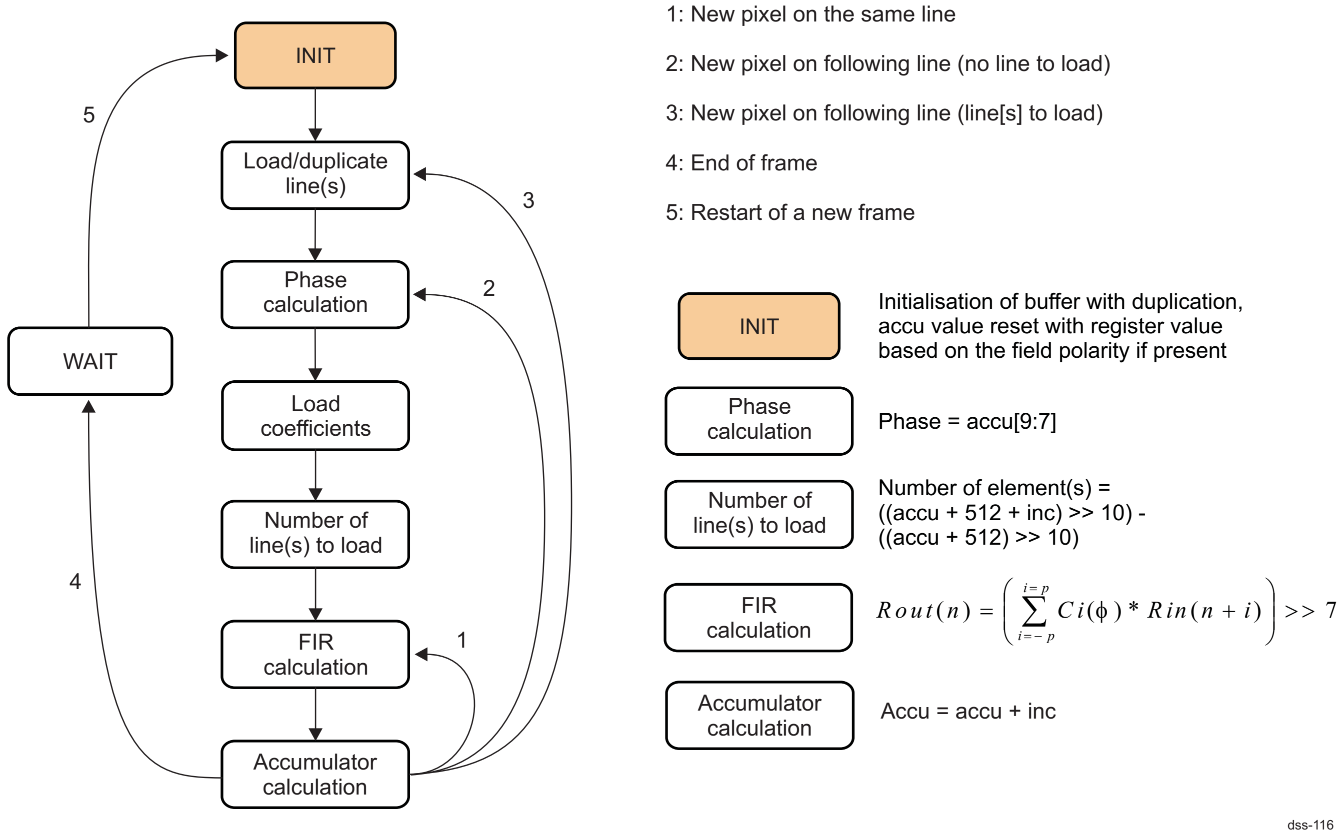


Figure 13-75 presents the horizontal up/downsampling FSM.

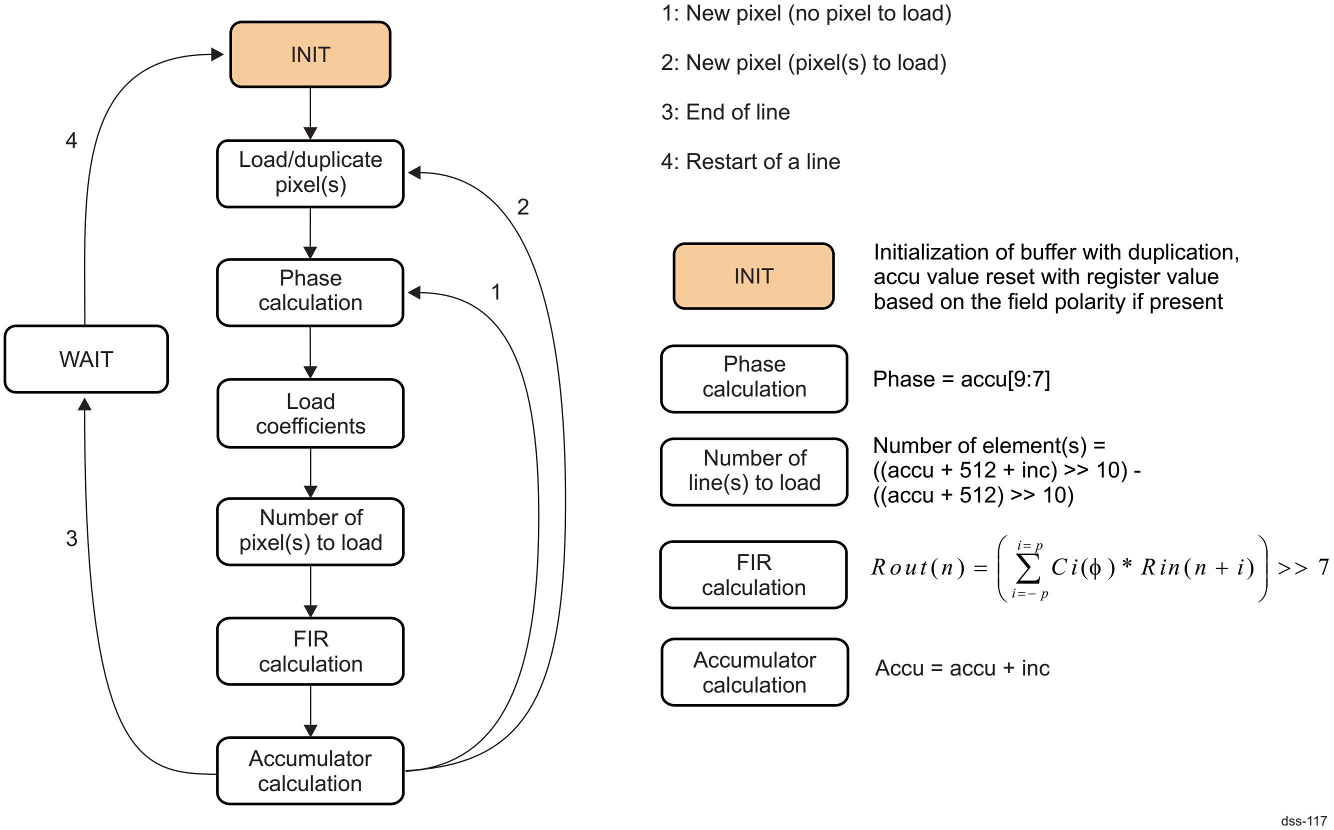
Figure 13-75. Horizontal Up-/Down-Sampling Algorithm



13.5.1.3 Scaling Settings

NOTE:

- In this section, the screen word refers to LCD panel or TV set.
- n indicates pipeline 0 or 1 because there are two video pipelines in the DISPC.

13.5.1.3.1 Register List

The following registers define the scaling registers for the video layer n configuration:

- DSS.DISPC_VIDn_BAj
- DSS.DISPC_VIDn_ATTRS
- DSS.DISPC_VIDn_FIR
- DSS.DISPC_VIDn_ACCUl
- DSS.DISPC_VIDn_FIR_COEF_H_i
- DSS.DISPC_VIDn_FIR_COEF_HV_i
- DSS.DISPC_VIDn_FIR_COEF_Vi

Table 13-31 lists the registers for programming the vertical FIR coefficients (3-tap configuration).

Table 13-31. Vertical FIR Coefficients Corresponding Table (3-Tap Configuration)

$C_x()$	FIR_VC$_x$()
$C_{-1}()$	FIR_VC$_2$()
$C_0()$	FIR_VC$_1$()

Table 13-31. Vertical FIR Coefficients Corresponding Table (3-Tap Configuration) (continued)

C$_{X}$()	**FIR_VC$_{X}$()**
C$_{1}$()	FIR_VC$_{0}$()

The corresponding registers for programming the vertical FIR coefficients (3-tap configuration) are:

- FIR_VC$_{2}$() = DSS.DISPC_VIDn_FIR_COEF_HV_i[31:24] FIR_VC2
- FIR_VC$_{1}$() = DSS.DISPC_VIDn_FIR_COEF_HV_i[23:16] FIR_VC1
- FIR_VC$_{0}$() = DSS.DISPC_VIDn_FIR_COEF_HV_i[15:8] FIR_VC0

Table 13-32 lists the registers for programming the vertical FIR coefficients (5-tap configuration).

Table 13-32. Vertical FIR Coefficients Corresponding Table (5-Tap Configuration)

C$_{X}$()	**FIR_VC$_{X}$()**
C$_{22}$()	FIR_VC$_{22}$()
C$_{-1}$()	FIR_VC$_{2}$()
C$_{0}$()	FIR_VC$_{1}$()
C$_{1}$()	FIR_VC$_{0}$()
C$_{00}$()	FIR_VC$_{00}$()

The corresponding registers for programming the vertical FIR coefficients (5-tap configuration) are:

- FIR_VC$_{22}$() = DSS.DISPC_VIDn_FIR_COEF_Vi[15:8] FIR_VC22
- FIR_VC$_{2}$() = DSS.DISPC_VIDn_FIR_COEF_HV_i[31:24] FIR_VC2
- FIR_VC$_{1}$() = DSS.DISPC_VIDn_FIR_COEF_HV_i[23:16] FIR_VC1
- FIR_VC$_{0}$() = DSS.DISPC_VIDn_FIR_COEF_HV_i[15:8] FIR_VC0
- FIR_VC$_{00}$() = DSS.DISPC_VIDn_FIR_COEF_Vi[7:0] FIR_VC00

Table 13-33 lists the registers for programming the horizontal FIR coefficients (5-tap configuration).

Table 13-33. Horizontal FIR Coefficients Corresponding Table (5-Tap Configuration)

C$_{X}$()	**FIR_HC$_{X}$()**
C$_{-2}$()	FIR_HC$_{4}$()
C$_{-1}$()	FIR_HC$_{3}$()
C$_{0}$()	FIR_HC$_{2}$()
C$_{1}$()	FIR_HC$_{1}$()
C$_{2}$()	FIR_HC$_{0}$()

The corresponding registers for programming the vertical FIR coefficients (3-tap configuration) are:

- FIR_HC$_{4}$() = DSS.DISPC_VIDn_FIR_COEF_HV_i[7:0] FIR_HC4
- FIR_HC$_{3}$() = DSS.DISPC_VIDn_FIR_COEF_H_i[31:24] FIR_HC3
- FIR_HC$_{2}$() = DSS.DISPC_VIDn_FIR_COEF_H_i[23:16] FIR_HC2
- FIR_HC$_{1}$() = DSS.DISPC_VIDn_FIR_COEF_H_i[15:8] FIR_HC1
- FIR_HC$_{0}$() = DSS.DISPC_VIDn_FIR_COEF_H_i[7:0] FIR_HC0

13.5.1.3.2 Enabling

The video pipeline #n is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRS[0].EN bit. While the video pipeline is enabled/disabled, the video layer is visible/not visible on the screen (LCD panel or TV set).

The video up/downsampling block for the video pipeline #n is programmed by setting the DSS.DISPC_VIDn_ATTRS[6:5] RESIZE_EN bit field:

- When the RESIZE_EN[1] bit is set to 1, the video vertical up/downsampling block is enabled. When set to 0, the vertical resize processing is disabled.
- When the RESIZE_EN[0] bit is set to 1, the video horizontal up/downsampling block is enabled. When set to 0, the horizontal resize processing is disabled.
- When the RESIZE_EN[1:0] is set to 0x3, both horizontal and vertical resize processing are enabled.

NOTE:

- Set a valid configuration before enabling the video up/downsampling block.
- Vertical and horizontal downsampling are limited to a 0.25 resize factor. When processing a down-scaling with a vertical factor between 0.5 and 0.25, a 5-tap filter configuration must be used. See Section 13.5.1.3.5 for more information concerning the filter coefficients.

13.5.1.3.3 Factor

The following register bit fields define the increment value of the video up/downsampling block for video pipeline n:

- Vertical up/downsampling increment value (DSS.DISPC_VIDn_FIR[27:16] FIR_V_INC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRVINC[11:0]} = 1024 \text{ x } \frac{\text{VIDORGSIZEY[10:0]}}{\text{VIDSIZEY[10:0]}} \tag{15}$$

dss-E118

NOTE:

- If the FIR_V_INC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VID_SIZE_Y[10:0] equals 0x1, VID_SIZE_Y[10:0] is replaced by 0x2 in the previous equation.
- The VID_ORG_SIZE_Y[10:0] and VID_SIZE_Y[10:0] bit field values must be programmed with the value desired minus 1.

- Horizontal up/downsampling increment value (the DSS.DISPC_VIDn_FIR[11:0] FIR_H_INC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRHINC[11:0]} = 1024 \text{ x } \frac{\text{VIDORGSIZEX[10:0]}}{\text{VIDSIZEX[10:0]}} \tag{16}$$

dss-E119

NOTE:

- If the FIR_H_INC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VID_SIZE_X[10:0] equals 1, VID_SIZE_X[10:0] is replaced by 2 in the previous equation.
- The VID_ORG_SIZE_X[10:0] and VID_SIZE_X[10:0] bit field values must be programmed with the value desired minus 1.

13.5.1.3.4 Initial Phase

- Vertical up/downsampling accumulator value DSS.DISPC_VIDn_ACCUl[25:16] VERTICAL_ACCU bit fields

  The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the vertical filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data.
- Vertical up/downsampling accumulator value DSS.DISPC_VIDn_ACCUl[9:0] VIDHORIZONTALACCU

bit fields

The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the horizontal filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data

Table 13-34 lists the vertical/horizontal accumulator values and phases

Table 13-34. Vertical/Horizontal Accumulator Phase

Accumulator Value	Phases
0	0
128	1
256	2
384	3
512	4
640	5
768	6
896	7

NOTE: For LCD output, the initial phase is always 0 (horizontal and vertical.) For TV output, the vertical phases (odd and even) can be nonzero values.

13.5.1.3.5 Coefficients

- **Vertical up/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_HV_i and DSS.DISPC_VIDn_FIR_COEF_V)**

  The 3-tap vertical up/downsampling coefficients are defined in DSS.DISPC_VIDn_FIR_COEF_HV_i registers. There are eight registers for the eight phases with three coefficients for each of them so a total of 24 programmable coefficients for the vertical up/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (central one).

  In addition, there are 2-tap vertical up/downsampling coefficients defined in DSS.DISPC_VIDn_FIR_COEF_Vi registers. There are eight registers for the eight phases with two coefficients for each of them so a total of 16 programmable coefficients for the vertical up/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients (C_{22}() and C_{00}()).

  In case of 5-tap configuration, both sets of registers, DSS.DISPC_VIDn_FIR_COEF_HV_i and DSS.DISPC_VIDn_FIR_COEF_V, are used. In case of 3-tap configuration, only one set of registers, DSS.DISPC_VIDn_FIR_COEF_HV, is used.

- **Horizontal up/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_H_i and DSS.DISPC_VIDn_FIR_COEF_HV)**

  The 5-tap horizontal up/downsampling coefficients are defined in DSS.DISPC_VIDn_FIR_COEF_H_i and DSS.DISPC_VIDn_FIR_COEF_HV_i registers. There are eight registers for the eight phases with five coefficients for each register, for a total of 40 programmable coefficients for the horizontal up/downsampling block.

  Each DSS.DISPC_VIDn_FIR_COEF_H_i register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (central one), and each DSS.DISPC_VIDn_FIR_COEF_HV_i contains one 8-bit signed coefficient.

Table 13-35 through Table 13-40 give the programmable coefficients for the FIR up/downsampling filters (Max-Fauque-Berthier method).

13.5.1.3.5.1 Up-Sampling

Table 13-35 gives the 24 coefficients to program the vertical upsampling (3-tap configuration).

Table 13-35. Up-Sampling Vertical Filter Coefficients (Three Taps)

Phases	FIR_VC$_2$()	FIR_VC$_1$()	FIR_VC$_0$()
0	0	128	0
1	3	123	2
2	12	111	5
3	32	89	7
4	0	64	64
5	7	89	32
6	5	111	12
7	2	123	3

Table 13-36 gives the 40 coefficients to program the vertical upsampling (5-tap configuration).

Table 13-36. Up-Sampling Vertical Filter Coefficients (Five Taps)

Phases	FIR_VC$_{22}$()	FIR_VC$_2$()	FIR_VC$_1$()	FIR_VC$_0$()	FIR_VC$_{00}$()
0	0	0	128	0	0
1	-1	13	124	-8	0
2	-2	30	112	-11	-1
3	-5	51	95	-11	-2
4	0	-9	73	73	-9
5	-2	-11	95	51	-5
6	-1	-11	112	30	-2
7	0	-8	124	13	-1

Table 13-37 gives the 40 coefficients to program the horizontal upsampling (5-tap configuration).

Table 13-37. Up-Sampling Horizontal Filter Coefficients (Five Taps)

Phases	FIR_HC$_4$()	FIR_HC$_3$()	FIR_HC$_2$()	FIR_HC$_1$()	FIR_HC$_0$()
0	0	0	128	0	0
1	-1	13	124	-8	0
2	-2	30	112	-11	-1
3	-5	51	95	-11	-2
4	0	-9	73	73	-9
5	-2	-11	95	51	-5
6	-1	-11	112	30	-2
7	0	-8	124	13	-1

The upsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H_0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_HV_0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_H_1 = 0x0D7CF800
- DSS.DISPC_VIDn_FIR_COEF_HV_1 = 0x037B02FF
- DSS.DISPC_VIDn_FIR_COEF_H_2 = 0x1E70F5FF
- DSS.DISPC_VIDn_FIR_COEF_HV_2 = 0x0C6F05FE
- DSS.DISPC_VIDn_FIR_COEF_H_3 = 0x335FF5FE
- DSS.DISPC_VIDn_FIR_COEF_HV_3 = 0x205907FB
- DSS.DISPC_VIDn_FIR_COEF_H_4 = 0xF74949F7
- DSS.DISPC_VIDn_FIR_COEF_HV_4 = 0x00404000

- DSS.DISPC_VIDn_FIR_COEF_H_5 = 0xF55F33FB
- DSS.DISPC_VIDn_FIR_COEF_HV_5 = 0x075920FE
- DSS.DISPC_VIDn_FIR_COEF_H_6 = 0xF5701EFE
- DSS.DISPC_VIDn_FIR_COEF_HV_6 = 0x056F0CFF
- DSS.DISPC_VIDn_FIR_COEF_H_7 = 0xF87C0DFF
- DSS.DISPC_VIDn_FIR_COEF_HV_7 = 0x027B0300

NOTE: In this case, the DSS.DISPC_VIDn_FIR_COEF_Vi registers are not used.

The upsampling coefficients register configuration (both vertical and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H_0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_HV_0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_V0 = 0x00000000
- DSS.DISPC_VIDn_FIR_COEF_H_1 = 0x0D7CF800
- DSS.DISPC_VIDn_FIR_COEF_HV_1 = 0x0D7CF8FF
- DSS.DISPC_VIDn_FIR_COEF_V1 = 0x0000FF00
- DSS.DISPC_VIDn_FIR_COEF_H_2 = 0x1E70F5FF
- DSS.DISPC_VIDn_FIR_COEF_HV_2 = 0x1E70F5FE
- DSS.DISPC_VIDn_FIR_COEF_V2 = 0x0000FEFF
- DSS.DISPC_VIDn_FIR_COEF_H_3 = 0x335FF5FE
- DSS.DISPC_VIDn_FIR_COEF_HV_3 = 0x335FF5FB
- DSS.DISPC_VIDn_FIR_COEF_V3 = 0x0000FBFE
- DSS.DISPC_VIDn_FIR_COEF_H_4 = 0xF74949F7
- DSS.DISPC_VIDn_FIR_COEF_HV_4 = 0xF7404000
- DSS.DISPC_VIDn_FIR_COEF_V04 = 0x000000F7
- DSS.DISPC_VIDn_FIR_COEF_H_5 = 0xF55F33FB
- DSS.DISPC_VIDn_FIR_COEF_HV_5 = 0xF55F33FE
- DSS.DISPC_VIDn_FIR_COEF_V5 = 0x0000FEFB
- DSS.DISPC_VIDn_FIR_COEF_H_6 = 0xF5701EFE
- DSS.DISPC_VIDn_FIR_COEF_HV_6 = 0xF5701EFF
- DSS.DISPC_VIDn_FIR_COEF_V6 = 0x0000FFFE
- DSS.DISPC_VIDn_FIR_COEF_H_7 = 0xF87C0DFF
- DSS.DISPC_VIDn_FIR_COEF_HV_7 = 0xF87C0D00
- DSS.DISPC_VIDn_FIR_COEF_V7 = 0x000000FF

13.5.1.3.5.2 Down-Sampling

Table 13-38 gives the 24 coefficients to program the vertical downsampling (3-tap configuration).

Table 13-38. Down-Sampling Vertical Filter Coefficients (Three Taps)

Phases	FIR_VC$_2$()	FIR_VC$_1$()	FIR_VC$_0$()
0	36	56	36
1	40	57	31
2	45	56	27
3	50	55	23
4	18	55	55
5	23	55	50
6	27	56	45

Phases	$FIR\_VC_2()$	$FIR\_VC_1()$	$FIR\_VC_0()$
7	31	57	40

Table 13-39 gives the 40 coefficients to program the vertical downsampling (5-tap configuration).

Table 13-39. Down-Sampling Vertical Filter Coefficients (Five Taps)

Phases	$FIR\_VC_{22}()$	$FIR\_VC_2()$	$FIR\_VC_1()$	$FIR\_VC_0()$	$FIR\_VC_{00}()$
0	0	36	56	36	0
1	4	40	55	31	-2
2	8	44	54	27	-5
3	-12	48	53	22	-7
4	-9	17	52	51	17
5	-7	22	53	48	12
6	-5	27	54	44	8
7	-2	31	55	40	4

Table 13-40 gives the 40 coefficients to program the horizontal downsampling (5-tap configuration).

Table 13-40. Down-Sampling Horizontal Filter Coefficients (Five Taps)

Phases	$FIR\_HC_4()$	$FIR\_HC_3()$	$FIR\_HC_2()$	$FIR\_HC_1()$	$FIR\_HC_0()$
0	0	36	56	36	0
1	4	40	55	31	-2
2	8	44	54	27	-5
3	-12	48	53	22	-7
4	-9	17	52	51	17
5	-7	22	53	48	12
6	-5	27	54	44	8
7	-2	31	55	40	4

The downsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H_0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_HV_0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_H_1 = 0x28371FFE
- DSS.DISPC_VIDn_FIR_COEF_HV_1 = 0x28391F04
- DSS.DISPC_VIDn_FIR_COEF_H_2 = 0x2C361BFB
- DSS.DISPC_VIDn_FIR_COEF_HV_2 = 0x2D381B08
- DSS.DISPC_VIDn_FIR_COEF_H_3 = 0x303516F9
- DSS.DISPC_VIDn_FIR_COEF_HV_3 = 0x3237170C
- DSS.DISPC_VIDn_FIR_COEF_H_4 = 0x11343311
- DSS.DISPC_VIDn_FIR_COEF_HV_4 = 0x123737F7
- DSS.DISPC_VIDn_FIR_COEF_H_5 = 0x1635300C
- DSS.DISPC_VIDn_FIR_COEF_HV_5 = 0x173732F9
- DSS.DISPC_VIDn_FIR_COEF_H_6 = 0x1B362C08
- DSS.DISPC_VIDn_FIR_COEF_HV_6 = 0x1B382DFB
- DSS.DISPC_VIDn_FIR_COEF_H_7 = 0x1F372804
- DSS.DISPC_VIDn_FIR_COEF_HV_7 = 0x1F3928FE

NOTE:

- In this case, the DSS.DISPC_VIDn_FIR_COEF_Vi registers are not used.
- In this case, the downsampling factor must be higher than 1/2.

The downsampling coefficients register configuration (both the vertical and the horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H_0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_HV_0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_V0 = 0x00000000
- DSS.DISPC_VIDn_FIR_COEF_H_1 = 0x28371FFE
- DSS.DISPC_VIDn_FIR_COEF_HV_1 = 0x28371F04
- DSS.DISPC_VIDn_FIR_COEF_V1 = 0x000004FE
- DSS.DISPC_VIDn_FIR_COEF_H_2 = 0x2C361BFB
- DSS.DISPC_VIDn_FIR_COEF_HV_2 = 0x2C361B08
- DSS.DISPC_VIDn_FIR_COEF_V2 = 0x000008FB
- DSS.DISPC_VIDn_FIR_COEF_H_3 = 0x303516F9
- DSS.DISPC_VIDn_FIR_COEF_HV_3 = 0x3035160C
- DSS.DISPC_VIDn_FIR_COEF_V3 = 0x00000CF9
- DSS.DISPC_VIDn_FIR_COEF_H_4 = 0x11343311

NOTE: This configuration must be used for vertical downsampling factors between 1/2 and 1/4

13.5.2 Display Low-Power Refresh Settings

This section describes the display low-power refresh application on the device. The display subsystem remains active while saving power by putting unused power domains and unused modules into idle mode. This process can be expanded to include the screen saver mode in which the MPU subsystem wakes up to update the frame buffer and then returns to idle mode. On the device platform, where power consumption is of high importance, the display modes must be configured properly to achieve optimal power savings

The display low-power refresh mode can be used in the following scenarios:

- During the period of time when there is no application running and the backlight turns off.
- Once the backlight turns off, the LCD display can be shut off or can be refreshed showing the time and date. The screen saver mode can be used to update the time every minute.

This section discusses the methodology for finding optimal power savings. These settings are detailed for a 16-bit, 240 x 320 pixel QVGA LCD.

13.5.2.1 Display Low-Power Refresh Overview

When the device is not in idle mode, meaning all clocks are on and the power is applied to all power domains, the following activity typically occurs with respect to the display subsystem:

- The MPU subsystem is processing
- The display subsystem DMA controller is moving data from the SDRAM frame buffer location to the display subsystem internal FIFO.
- The LCD data is being sent from the internal FIFO to the display panel.

When the MPU goes into idle mode, the following activity occurs:

- The display subsystem DMA controller remains active, moving data from the SDRAM frame buffer to the internal FIFO.
- The SDRAM will go in and out of self-refresh between transfers.
- The display subsystem internal FIFO will continue to send LCD data to the display panel.

This procedure is named as the display low-power refresh scenario.

NOTE: In the device, the display subsystem has its own power domain (the DSS power domain).

13.5.2.2 Display Subsystem Clock

13.5.2.2.1 Display Subsystem Clock Configuration

The display subsystem contains one functional clock source, which is the DSS functional clock 1 (DSS1_ALWON_FCLK):

- DSS1_ALWON_FCLK is sourced from DPLL4 (DPLL4_ALWON_FCLK), with several multipliers available and is configured in the PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 bit field.

The pixel clock is set as DSS1_ALWON_FCLK by configuring the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit.

The LCD logic clock is determined by the DSS.DISPC_DIVISOR[23:16] LCD bit field. This divisor is used on the DSS functional clock that is selected in the DSS_CONTROL register (either DSS1_ALWON_FCLK or DSS2_ALWON_FCLK). This LCD divisor selects the logical clock frequency which is used to clock the logic in the display subsystem. For some applications there is a required minimum logical clock frequency. The lower the logical clock frequency then the lower the power consumption.

The pixel clock is determined by setting the DSS.DISPC_DIVISOR[7:0] PCD bit field. This divisor is used on the LCD logic clock.

In the following example, the DPLL4 clock (DPLL4_ALWON_FCLK) is enabled and running at 266 MHz:

The PRCM.CM_CLKSEL2_PLL[19:8] PERIPH_DPLL_MULT bit field is set to 0x4 and the PRCM.CM_CLKSEL2_PLL[6:0] PERIPH_DPLL_DIV bit field is set to 0x1 (DPLL4 x 4/(1+1)):

DPLL4_ALWON_FCLKOUT= DPLL4_ALWON_FCLK(266MHz) x 4/2 = 532 MHz

NOTE: The DPLL4_ALWON_FCLOUT clock is an internal clock in DPLL4 module after the DPLL_MULT and DPLL_DIV stages. The DPLL4_M4_CLK clock is one of the DPLL4 output clocks and is the clock source for DSS1_ALWON_FCLK.

The DSS.DSS_CONTROL[0] DSS_CLK_SWITCH bit is set to 0x0 to select DSS1_ALWON_FCLK as the display subsystem functional clock:

DSS1_ALWON_FCLK = DPLL4_M4_CLK

The PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 bit field is set to 0x08:

$$\text{DSS1\_ALWON\_FCLK} = \frac{\text{DPLL4\_ALWON\_FCLKOUT (532MHz)}}{8} = 66.5\ \text{MHz} \tag{17}$$

dss-E120

The DSS.DISPC_DIVISOR[23:16] LCD bit field is set to 0x01:

$$\text{LogicClock} = \frac{\text{DSS1\_ALWON\_FCLK(66.5MHz)}}{1} = 66.5\ \text{Mhz} \tag{18}$$

dss-E121

The DSS.DISPC_DIVISOR[6:0] PCD bit field is set to 0x0C:

$$\text{PixelClock} = \frac{\text{LogicClock(66.5MHz)}}{12} = 5.54\ \text{Mhz} \tag{19}$$

dss-E122

13.5.2.2.1.1 Pixel Clock Frequency Settings to Reduce Power Consumption

Power consumption is reduced when a low pixel clock frequency is used. If the clock frequency is set too low, however, the frames-per-second (FPS) are reduced. This can result in visible flickering on the screen each time the screen is refreshed. To avoid electrical polarization problems, refer to the appropriate LCD panel datasheet to determine the maximum range of pixel clock frequency variation. To save power, therefore, the pixel clock frequency during low-power mode must be set as low as possible, but high enough to eliminate visible flickering

13.5.2.2.1.2 Display Subsystem Divider Settings to Reduce Power Consumption

The pixel clock is determined by the DSS.DISPC_DIVISOR[7:0] PCD and DSS.DISPC_DIVISOR[23:16] LCD settings. In most cases, the LCD[7:0] bit field is set to 0x1 and the PCD[7:0] bit field is used as the main divider. To reduce power consumption, software users should investigate if the DSS.DISPC_DIVISOR[23:16] LCD bit field can be set to a value other than 0x1 and then decrease DSS.DISPC_DIVISOR[7:0] PCD bit field value. For example, if the desired pixel clock is 1.625 MHz with a 13-MHz functional clock, then this pixel clock can be achieved by setting DSS.DISPC_DIVISOR[23:16] LCD to 0x1 and DSS.DISPC_DIVISOR[7:0] PCD to 0x8. The same pixel clock can be achieved by setting DSS.DISPC_DIVISOR[23:16] LCD to 0x2 and DSS.DISPC_DIVISOR[7:0] PCD to 0x4.

13.5.2.2.2 Display Subsystem Clock Enable

To take the DSS out of reset, all DSS-related clocks must be enabled, and the DPLL4 clock must be enabled. After taking the DSS out of reset, these clocks can be disabled if they are not used. The following clocks must be enabled before the DSS can come out of reset:

- PRCM.CM_FCLKEN_DSS[0] EN_DSS1 = 0x1
- PRCM.CM_FCLKEN_DSS[1] EN_DSS2 = 0x1
- PRCM.CM_FCLKEN_DSS[2] EN_TV = 0x1
- PRCM.CM_ICLKEN_DSS[0] EN_DSS = 0x1
- PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL = 0x7

Once these clocks are enabled, the display subsystem can be taken out of reset.

The following sections explain the display low-power mode configuration options, which are determined by product requirements (LCD panel type).

13.5.2.3 Autoidle and Smart Idle

13.5.2.3.1 Autoidle

To further save power consumption, the autoidle feature at the module can be enabled for the active modules. For example, the PRCM and the system control modules are active during this mode. By enabling the autoidle feature, the clocks at the module level are gated when they are not needed.

The RFBI, display controller, and L4 interfaces can internally gate their clocks to decrease power consumption if no transaction is present on the related bus. The following bits must be set to enable this functionality:

- DSS.DSS_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display subsystem
- DSS.RFBI_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the RFBI

- DSS.DISPC_SYSCFG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display controller
- DSS.DISPC_CFG[9] FUNC_GATED bit (1: Functional clocks gated enabled, 0: Functional clocks gated disabled) for the display controller

13.5.2.3.2 Smart-Idle

The smart-idle feature can be enabled to allow the module to enter idle when the clocks are not needed. The smart-idle feature can be enabled for the display subsystem submodules to further save power consumption:

- Display controller: DSS.DISPC_SYSCFG[4:3] SIDLEMODE
- RFBI: DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE

13.5.2.4 FIFO Thresholds

The display subsystem internal FIFO is used to move data to the LCD panel. This FIFO is filled by the display subsystem DMA controller. The DMA controller is triggered to start and stop based on two thresholds:

- DSS.DISPC_GFX_FIFO_THR[11:0] GFX_FIFO_LOW_THR
- DSS.DISPC_GFX_FIFO_THR[27:16] GFX_FIFO_HIGH_THR

When the level of the FIFO reaches the low threshold, the internal DMA controller begins to fill the FIFO With the data in the frame buffer. Once the amount of pixel data reaches the high threshold, the internal DMA controller stops.

13.5.2.4.1 FIFO Threshold Settings to Reduce Power Consumption

Power consumption is reduced by increasing the difference between the high and low FIFO threshold levels, thereby leaving the SDRAM in self-refresh for a longer period of time. To perform this reduction, consider the following:

- The low FIFO threshold level must be as low as possible, but not low enough to cause any underflow.
- The high FIFO threshold level must not exceed the FIFO size minus one burst. A value above this limit results in the DMA controller trying to fill the FIFO to a level that cannot be reached, which will increase power consumption.
- The difference between high and low FIFO threshold levels must not be less than one burst size. These settings do not reduce power consumption because the SDRAM never goes into self-refresh, but they will avoid underflow.

13.5.2.5 Vertical and Horizontal Timings

The vertical and horizontal timings and the pixel clock speed determine the number of frames updated per second. Figure 13-76 shows the timings for a 240 x 320 pixel QVGA LCD panel. If the pulse width (also called blanking) and the front porch parameters are increased, more setup time is added before the data is transferred. This additional time is beneficial for delaying the data transfer if the data is not ready because of bandwidth limitations. Care must be taken to determine the fps when modifying these parameters.

Use the following formula to determine the fps for a 240 x 320 QVGA LCD:

$$fps = \frac{1}{[(Hsw + 1) + (Hfp + 1) + 240 + (Hbp + 1)] \times [(Vsw + 1) + Vfp + 320 + Vbp)] \times (PCLK)} \qquad (20)$$

dss-E123

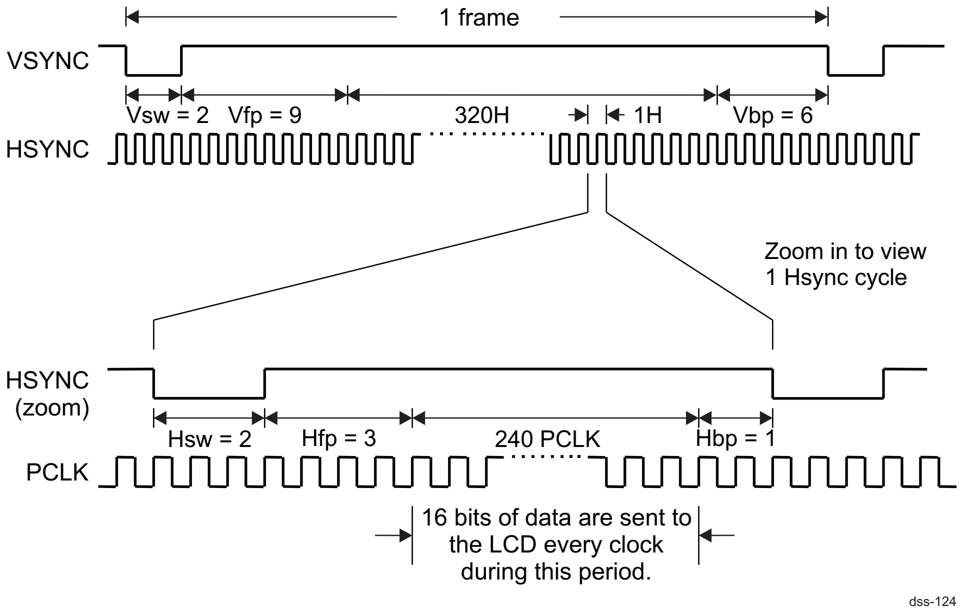
With:

- Hsw: DSS.DISPC_TIMING_H[7:0] HSW bit field value
- Hfp: DSS.DISPC_TIMING_H[19:8] HFP bit field value
- Hbp: DSS.DISPC_TIMING_H[31:20] HBP bit field value
- Vsw: DSS.DISPC_TIMING_V[7:0] VSW bit field value
- Vfp: DSS.DISPC_TIMING_V[19:8] VFP bit field value

- Vbp: DSS.DISPC_TIMING_V[31:20] VBP bit field value
- PCLK: Pixel clock period

The horizontal (Hsw) and vertical (Vsw) pulse widths and the horizontal front (Hfp) and back (Hbp) porches are increased by 1 because the value is programmed as the desired value minus 1.

Figure 13-76. QVGA LCD Timings



The fps for the example of 6-MHz pixel clock with the setting shown in Figure 13-76 is as follows:

$$fps = \frac{1}{[(2 + 1) + 4 + 240 + 2] \times [(2 + 1) + 9 + 320 + 6] \times 166.67 \times 10^{-9}}$$

dss-E125

$$fps = 71.57Hz \qquad (21)$$

13.5.2.5.1 Horizontal and Vertical Timing Settings to Reduce Power Consumption

The number of fps that the screen is refreshed is also determined by the vertical and horizontal timings. Consequently, longer timings between frames (blanking periods) reduce the fps and reduce average power consumption. Shorter blanking periods increase fps and increases power consumption. If the blanking between frames is too small, a FIFO underflow may occur.

13.6 Registers

13.6.1 DSS_DISPC Registers

Table 13-41 lists the memory-mapped registers for the DSS_DISPC. All register offset addresses not listed in Table 13-41 should be considered as reserved locations and the register contents should not be modified.

Table 13-41. DSS_DISPC Registers

Table 13-43. DISPC_SYSCFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	SOFTRESET	R/W	0h	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0h (R/W) = Normal mode 1h (R/W) = The module is reset.
0	AUTOIDLE	R/W	1h	Internal interface clock gating strategy 0h (R/W) = Interface clock is free-running 1h (R/W) = Automatic L3 and L4 interface clock gating strategy is applied based on interface activity

13.6.1.3 DISPC_SYSSTS Register (offset = 14h) [reset = 1h]

DISPC_SYSSTS is shown in Figure 13-79 and described in Table 13-44.

This register provides status information about the module, excluding interrupt status information.

13.6.1.4 DISPC_IRQSTS Register (offset = 18h) [reset = 0h]

DISPC_IRQSTS is shown in Figure 13-80 and described in Table 13-45.

This register regroups all the status of module internal events that generate an interrupt. A write of 1 to a given bit
resets the bit

Table 13-48. DISPC_CFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	PALETTEGAMMA_TBL	R/W	0h	Palette/Gamma Table selection 0h (R/W) = LUT used as palette (only if graphics format is BITMAP1, 2, 4, and 8) 1h (R/W) = LUT used as gamma table (only if graphics format is NOT BITMAP1, 2, 4, and 8 or no graphics window present)
2-1	LOAD_MODE	R/W	0h	Loading Mode for the Palette/Gamma Table 0h (R/W) = Palette/Gamma Table and data are loaded every frame 1h (R/W) = Palette/Gamma Table to be loaded. Users set the bit when the palette/gamma table has to be loaded. H/W resets the bit when table has been loaded. (DISPC_GFX_ATTRIBUTES. GfxEnable has to be set to 1) 2h (R/W) = Frame data only loaded every frame 3h (R/W) = Palette/Gamma Table and frame data loaded on first frame then switch to 10 (H/W)
0	PIXEL_GATED	R/W	0h	Pixel Gated Enable (only for Active Matrix Display) 0h (R/W) = Pixel Gated Enable (only for Active Matrix Display) 1h (R/W) = Pixel clock only toggles when there is valid data to display. (only in Active Matrix mode)

13.6.1.8 DISPC_DEFAULT_COLOR_0 Register (offset = 4Ch + [i * 4h]) [reset = 0h]

DISPC_DEFAULT_COLOR_0 is shown in Figure 13-84 and described in Table 13-49.

The control register allows to configure the default solid background color for the LCD (DISPC_DEFAULT_COLOR_0) and for 24-bit digital output (DISPC_DEFAULT_COLOR_1). Shadow register, updated on VFP start period for DISPC_DEFAULT_COLOR_0 and EVSYNC for DISPC_DEFAULT_COLOR_1

13.6.1.9 DISPC_TRANS_COLOR_0 Register (offset = 54h + [i * 4h]) [reset = 0h]

DISPC_TRANS_COLOR_0 is shown in Figure 13-85 and described in Table 13-50.

The register sets the transparency color value for the video/graphics overlays for the LCD output (DISPC_TRANS_COLOR_0) for 24-bit digital output(DISPC_TRANS_COLOR_1).
Shadow register, updated on VFP start period for DISPC_TRANS_COLOR_0 and EVSYNC for DISPC_TRANS_COLOR_1

Figure 13-85. DISPC_TRANS_COLOR_0 Register

10-0	PPL	R/W	0h	Pixels per line Encoded value (from 1 to 2048) to specify the number of pixels contains within each line on the display (program to value minus one). When running in normal mode (stall mode is bypassed by setting DSS.DISPC_CONTROL[11] STALLMODE =0) the line width must be set to a value multiple of 8 pixels (ex: PPL=0x7)

13.6.1.19 DISPC_GFX_BA_0 Register (offset = 80h + [i * 4h]) [reset = 0h]

DISPC_GFX_BA_0 is shown in Figure 13-95 and described in Table 13-60.

The register configures the base address of the graphics buffer displayed in the graphics window (0 1 :for ping-pong mechanism with external trigger, based on the field polarity, 0 only used when graphics pipeline on the LCD
output and 0 1 when on the 24-bit digital output).
Shadow register, updated on VFP start period or EVSYNC.

Table 13-63. DISPC_GFX_ATTRS Register Field Descriptions

Bit	Field	Type	Reset	Description
31-29	RESERVED	R/W	0h	
28	PRE_MULTIPLY_ALPHA	R/W	0h	The field configures the DISPC GFX to process incoming data as pre-multiplied alpha data or non premultiplied alpha data. Default setting is non pre-multiplied alpha data 0h (R/W) = Non pre-multiplyalpha data color component 1h (R/W) = Pre-multiplyalpha data color component
27-16	RESERVED	R/W	0h	
15	GFX_SELF_REFRESH	R/W	0h	Enables the self refresh of the graphics window from its own FIFO only 0h (R/W) = The graphics pipeline accesses the interconnect to fetch data from the system memory 1h (R/W) = The graphics pipeline does not need anymore to fetch data from memory. Only the graphics FIFO is used. It takes effect after the frame has been loaded in the FIFO
14	GFX_ARBITRATION	R/W	0h	Determines the priority of the graphics pipeline. The graphics pipeline is one of the high priority pipeline. The arbitration wheel gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them 0h (R/W) = The graphics pipeline is one of the normal priority pipeline 1h (R/W) = The graphics pipeline is one of the high priority pipeline
13-12	GFX_ROTATION	R/W	0h	Graphics rotation flag (used only in case of RGB24 packed format) 0h (R/W) = No rotation 1h (R/W) = Rotation by 90 degrees 2h (R/W) = Rotation by 180 degrees 3h (R/W) = Rotation by 270 degrees

Table 13-63. DISPC_GFX_ATTRS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11	GFX_FIFO_PRELOAD	R/W	0h	Graphics preload value 0h (R/W) = H/W prefetches pixels up to the preload value defined in the preload register. 1h (R/W) = H/W prefetches pixels up to high threshold value
10	GFX_ENDIAN	R/W	0h	Graphics endianness 0h (R/W) = Little endian operation is selected 1h (R/W) = Big endian operation is selected
9	GFX_NIBBLE_MODE	R/W	0h	Graphics Nibble Mode (only for 1, 2 and 4 BPP) 0h (R/W) = Nibble mode is disabled 1h (R/W) = Nibble mode is enabled
8	GFX_CHANNEL_OUT	R/W	0h	Graphics Channel Out configuration 0h (R/W) = LCD output selected 1h (R/W) = 24-bit output selected
7-6	GFX_BURST_SIZE	R/W	0h	Graphics DMA Burst Size 0h (R/W) = 4x32bit bursts 1h (R/W) = 8x32bit bursts 2h (R/W) = 16x32bit bursts 3h (R/W) = 3
5	GFX_REPLICATION_EN	R/W	0h	GfxReplicationEnable 0h (R/W) = Disable Graphics replication logic 1h (R/W) = Enable Graphics replication logic

0	GFX_EN	R/W	0h	GfxEnable 0h (R/W) = Graphics disabled (graphics pipeline inactive and graphics window not present) 1h (R/W) = Graphics enabled (graphics pipeline active and graphics window present on the screen)

13.6.1.23 DISPC_GFX_FIFO_THR Register (offset = A4h) [reset = 3FF03C0h]

DISPC_GFX_FIFO_THR is shown in Figure 13-99 and described in Table 13-64.

The register configures the graphics FIFO.
Shadow register, updated on VFP start period or EVSYNC.

Figure 13-99. DISPC_GFX_FIFO_THR Register

13.6.1.34 DISPC_VID1_FIFO_SIZE_STS Register (offset = D4h) [reset = 400h]

DISPC_VID1_FIFO_SIZE_STS is shown in Figure 13-110 and described in Table 13-75.

The register defines the video FIFO size for video pipeline #n.

Figure 13-110. DISPC_VID1_FIFO_SIZE_STS Register

13.6.1.35 DISPC_VID1_ROW_INC Register (offset = D8h) [reset = 1h]

DISPC_VID1_ROW_INC is shown in Figure 13-111 and described in Table 13-76.

The register configures the number of bytes to increment at the end of the row for the buffer associated with video window #n.
Shadow register, updated on VFP start period or EVSYNC.

Figure 13-111. DISPC_VID1_ROW_INC Register

Bit	Field	Type	Reset	Description
31-0	ROW_INC	R/W	1h	Number of bytes to increment at the end of the row Encoded signed value (from (-2^31)-1 to 2^31) to specify the number of bytes to increment at the end of the row in the video buffer. The value 0 is invalid. The value 1 means next pixel. The value 1+n*BPP means increment of n pixels. The value 1- (n+1)*BPP means decrement of n pixels.

13.6.1.36 DISPC_VID1_PIXEL_INC Register (offset = DCh) [reset = 1h]

DISPC_VID1_PIXEL_INC is shown in Figure 13-112 and described in Table 13-77.

The register configures the number of bytes to increment between two pixels for the buffer associated with video
window #n.
Shadow register, updated on VFP start period or EVSYNC

The value 0 is invalid. The value 1 means next pixel. The value 1+n*BPP means increment of n pixels. The value 1-(n+1)*BPP means decrement of n pixels

13.6.1.37 DISPC_VID1_FIR Register (offset = E0h) [reset = 0h]

DISPC_VID1_FIR is shown in Figure 13-113 and described in Table 13-78.

The register configures the resize factors for horizontal and vertical up-/down-sampling of video window #n.
Shadow register, updated on VFP start period or EVSYNC

Figure 13-113. DISPC_VID1_FIR Register

12-0	FIR_H_INC	R/W	0h	Horizontal increment of the up-/down-sampling filter Encoded value (from 1 to 4096). The value 0 is invalid. Values greater than 4096 are invalid.

13.6.1.38 DISPC_VID1_PICTURE_SIZE Register (offset = E4h) [reset = 0h]

DISPC_VID1_PICTURE_SIZE is shown in Figure 13-114 and described in Table 13-79.

The register configures the size of the video picture associated with video layer #nbefore up-/down-scaling.
Shadow register, updated on VFP start period or EVSYNC.

Figure 13-114. DISPC_VID1_PICTURE_SIZE Register

15-11	RESERVED	R/W	0h	
10-0	VID_ORG_SIZE_X	R/W	0h	Number of pixels of the video picture Encoded value (from 1 to 2048) to specify the number of pixels of the video picture in memory (program to value minus one). The size is limited to the size of the line buffer of the vertical sampling block in case the video picture is processed by the vertical filtering unit.

13.6.1.39 DISPC_VID1_ACCU_0 to DISPC_VID1_ACCU_1 Register (offset = E8h to ECh) [reset = 0h]

DISPC_VID1_ACCU_0 to DISPC_VID1_ACCU_1 is shown in Figure 13-115 and described in Table 13-80.

The register configures the resize accumulator init values for horizontal and vertical up-/down-sampling of video
window #n (#I for ping-pong mechanism with external trigger, based on the field polarity)
Shadow register, updated on VFP start period or EVSYNC.

Figure 13-115. DISPC_VID1_ACCU_0 to DISPC_VID1_ACCU_1 Register

Bit	Field	Type	Reset	Description
31-29	RESERVED	R/W	0h	
28	PRE_MULTIPLY_ALPHA	R/W	0h	The field configures the DISPC VID2 to process incoming data as pre-multiplied alpha data or non pre-multiplied alpha data. Default setting is non pre-multiplied alpha data. 0h (R/W) = Non pre-multiplyalpha data color component 1h (R/W) = Premultiplyalpha data color component
27-25	RESERVED	R/W	0h	
24	SELF_REFRESH	R/W	0h	Enables the self refresh of the video window from its own FIFO only. 0h (R/W) = The video pipeline accesses the interconnect to fetch data from the system memory 1h (R/W) = The video pipeline does not need anymore to fetch data from memory. Only the video FIFO is used. It takes effect after the frame has been loaded in the FIFO
23	ARBITRATION	R/W	0h	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration wheel gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0h (R/W) = The video pipeline is one of the normal priority pipeline 1h (R/W) = The video pipeline is one of the high priority pipeline
22	LINE_BUFFER_SPLIT	R/W	0h	Video vertical line buffer split 0h (R/W) = Vertical line buffers are not split 1h (R/W) = Vertical line buffers are split into two
21	VERTICAL_TAPS	R/W	0h	Video vertical resize tap number 0h (R/W) = Three taps are used for the vertical filtering logic. The other two taps are not used 1h (R/W) = Five taps are used for the vertical filtering logic

Table 13-91. DISPC_VID2_ATTRS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	OPTIMIZATION	R/W	0h	Video optimization in case of 0h (R/W) = The DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory). 1h (R/W) = The DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory). The bit field [21] VIDVERTICALTAPS shall be set to 0x1, bit field [22] VIDLINEBUFFERSPLIT to 0x1, and all scaler registers shall be configured even for 1:1 ratio. Even width is required for the input picture when 5 taps are used.
19	FIFO_PRELOAD	R/W	0h	Video preload value 0h (R/W) = H/W prefetches pixels up to the preload value defined in the preload register 1h (R/W) = H/W prefetches pixels up to the high threshold value.
18	ROW_REPEAT_EN	R/W	0h	Video Row Repeat (YUV case only when rotating 90 or 270-degree) 0h (R/W) = Row of VIDn won't be read twice 1h (R/W) = The Row data are fetched twice to extract both the Y components
17	ENDIAN	R/W	0h	Video Endianness 0h (R/W) = Little endian operation is selected 1h (R/W) = Big endian operation is selected.
16	CHANNEL_OUT	R/W	0h	Video Channel Out configuration 0h (R/W) = LCD output selected 1h (R/W) = 24 bit output selected
15-14	BURST_SIZE	R/W	0h	Video DMA Burst Size 0h (R/W) = 4x32bit bursts 1h (R/W) = 8x32bit bursts 2h (R/W) = 16x32bit bursts 3h (R/W) = 3
13-12	ROTATION	R/W	0h	Video Rotation Flag 0h (R/W) = No rotation or VidFormat is RGB 1h (R/W) = Rotation by 90 degrees 2h (R/W) = Rotation by 180 degrees 3h (R/W) = Rotation by 270 degrees
11	FULL_RANGE	R/W	0h	VidFullRange 0h (R/W) = Limited range selected: 16 subtracted from Y before color space conversion 1h (R/W) = Full range selected: Y is not modified before the color space conversion
10	REPLICATION_EN	R/W	0h	VidReplicationEnable 0h (R/W) = Disable Video replication logic 1h (R/W) = Enable Video replication logic
9	COLOR_CONV_EN	R/W	0h	VidColorConvEnable 0h (R/W) = Disable Color Space Conversion CbYCr to RGB 1h (R/W) = Enable Color Space Conversion CbYCr to RGB

Table 13-91. DISPC_VID2_ATTRS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	VRESIZE_CONF	R/W	0h	Video Vertical Resize Configuration 0h (R/W) = Up-sampling selected 1h (R/W) = Down-sampling selected
7	HRESIZE_CONF	R/W	0h	Video Horizontal Resize Configuration 0h (R/W) = Up-sampling selected 1h (R/W) = Down-sampling selected
6-5	RESIZE_EN	R/W	0h	Video Resize Enable 0h (R/W) = Disable the resize processing 1h (R/W) = Enable the horizontal resize processing 2h (R/W) = Enable the vertical resize processing 3h (R/W) = Enable both horizontal and vertical resize processing
4-1	FMT	R/W	0h	Video2 channel Format Other enums: Reserved (all other values: 0x0 and 0x3, 0x7, and 0xF) 0h (R/W) = RESERVED : 0 1h (R/W) = RESERVED : 1 2h (R/W) = RESERVED : 2 3h (R/W) = RESERVED : 3 4h (R/W) = RGB 12 (16-bit container) 5h (R/W) = ARGB 16 6h (R/W) = RGB 16 7h (R/W) = RESERVED : 7 8h (R/W) = RGB 24 (un-packed in 32-bit container) 9h (R/W) = RGB 24 (packed in 24-bit container) Ah (R/W) = YUV2 4:2:2 co-sited Bh (R/W) = UYVY 4:2:2 co-sited Ch (R/W) = ARGB 32 Dh (R/W) = RGBA 32 Eh (R/W) = RGBx 32 (24-bit RGB aligned on MSB of the 32-bit container) Fh (R/W) = RESERVED : 15
0	EN	R/W	0h	VidEnable 0h (R/W) = Video disabled (video pipeline inactive and window not present) 1h (R/W) = Video enabled (video pipeline active and window present on the screen)

13.6.1.51 DISPC_VID2_FIFO_THR Register (offset = 160h) [reset = 3C003FFh]

DISPC_VID2_FIFO_THR is shown in Figure 13-127 and described in Table 13-92.

The register configures the video FIFO associated with video pipeline #n.
Shadow register, updated on VFP start period or EVSYNC.

Figure 13-127. DISPC_VID2_FIFO_THR Register

13.6.1.52 DISPC_VID2_FIFO_SIZE_STS Register (offset = 164h) [reset = 400h]

DISPC_VID2_FIFO_SIZE_STS is shown in Figure 13-128 and described in Table 13-93.

The register defines the video FIFO size for video pipeline #n.

Figure 13-128. DISPC_VID2_FIFO_SIZE_STS Register

13.6.1.53 DISPC_VID2_ROW_INC Register (offset = 168h) [reset = 1h]

DISPC_VID2_ROW_INC is shown in Figure 13-129 and described in Table 13-94.

The register configures the number of bytes to increment at the end of the row for the buffer associated with video
window #n.
Shadow register, updated on VFP start period or EVSYNC.

Figure 13-129. DISPC_VID2_ROW_INC Register

31-0	ROW_INC	R/W	1h	Number of bytes to increment at the end of the row Encoded signed value (from (-2^31)-1 to 2^31) to specify the number of bytes to increment at the end of the row in the video buffer. The value 0 is invalid. The value 1 means next pixel. The value 1+n*BPP means increment of n pixels. The value 1- (n+1)*BPP means decrement of n pixels.

13.6.1.54 DISPC_VID2_PIXEL_INC Register (offset = 16Ch) [reset = 1h]

DISPC_VID2_PIXEL_INC is shown in Figure 13-130 and described in Table 13-95.

The register configures the number of bytes to increment between two pixels for the buffer associated with video
window #n.
Shadow register, updated on VFP start period or EVSYNC

Figure 13-130. DISPC_VID2_PIXEL_INC Register

15-13	RESERVED	R/W	0h	
12-0	FIR_H_INC	R/W	0h	Horizontal increment of the up-/down-sampling filter Encoded value (from 1 to 4096). The value 0 is invalid. Values greater than 4096 are invalid.

13.6.1.56 DISPC_VID2_PICTURE_SIZE Register (offset = 174h) [reset = 0h]

DISPC_VID2_PICTURE_SIZE is shown in Figure 13-132 and described in Table 13-97.

The register configures the size of the video picture associated with video layer #nbefore up-/down-scaling.
Shadow register, updated on VFP start period or EVSYNC.

Figure 13-132. DISPC_VID2_PICTURE_SIZE Register

26-16	VID_ORG_SIZE_Y	R/W	0h	Number of lines of the video picture Encoded value (from 1 to 2048) to specify the number of lines of the video picture in memory (program to value minus one)
15-11	RESERVED	R/W	0h	
10-0	VID_ORG_SIZE_X	R/W	0h	Number of pixels of the video picture Encoded value (from 1 to 2048) to specify the number of pixels of the video picture in memory (program to value minus one). The size is limited to the size of the line buffer of the vertical sampling block in case the video picture is processed by the vertical filtering unit.

13.6.1.57 DISPC_VID2_ACCU_0 to DISPC_VID2_ACCU_1 Register (offset = 178h to 17Ch) [reset = 0h]

DISPC_VID2_ACCU_0 to DISPC_VID2_ACCU_1 is shown in Figure 13-133 and described in Table 13-98.

The register configures the resize accumulator init values for horizontal and vertical up-/down-sampling of video
window #n (#I for ping-pong mechanism with external trigger, based on the field polarity)
Shadow register, updated on VFP start period or EVSYNC.

Figure 13-133. DISPC_VID2_ACCU_0 to DISPC_VID2_ACCU_1 Register

4-0	NB_BITS_PIXEL1	R/W	0h	Number of bits Number of bits from the pixel #1 (value from 0 to 16 bits). The values from 17 to 31 are invalid.

13.6.1.66 DISPC_VID1_FIR_COEF_V_0 to DISPC_VID1_FIR_COEF_V_7 Register (offset = 1E0h to 1FCh) [reset = 0h]

DISPC_VID1_FIR_COEF_V_0 to DISPC_VID1_FIR_COEF_V_7 is shown in Figure 13-142 and described in Table 13-107.

This bank of registers configures the down/up/down-scaling coefficients for the vertical resize of the video picture
associated with video window #n for phases 0 to 7. Shadow register, updated on VFP start period or EVSYNC.

13.6.3.16 RFBI_DATA_CYCLE2_0 Register (offset = 70h + [i * 18h]) [reset = 0h]

RFBI_DATA_CYCLE2_0 is shown in Figure 13-171 and described in Table 13-138.

The control register configures the RFBI data format for 2nd cycle.

Camera (VPFE)

This chapter describes the camera (VPFE) of the device.

NOTE: The Camera (VPFE) is not supported for the AMIC120.

Topic **Page**

14.1 Introduction

14.1.1 VPFE Features

The general features of the VPFE module include:

- A buffer memory for interfacing to the DMA at the chip level and preventing the CCDC module from overflowing.
- Support for conventional Bayer pattern and Foveon sensor formats
- Generates HD/VD timing signals and field ID to an external timing generator or can synchronize to the external timing generator
- Support for progressive and interlaced sensors (hardware support for up to 2 fields and firmware support for higher number of fields, typically 3-, 4-, and 5-field sensors)
- Support for up to the lesser of 75 MHz or 1/2 dma_ocp_clk sensor clock in the normal mode of operation
- Support for REC656/CCIR-656 standard (YCbCr 422 format, either 8- or 16-bit)
- Support for YCbCr 422 format, either 8- or 16-bit with discrete H and VSYNC signals.
- Support for up to 16-bit input
- Generates optical black clamping signals
- Support for digital clamping and black level compensation
- Support for 10-bit to 8-bit A-law compression
- Support for a low-pass filter prior to writing to SDRAM. If this filter is enabled, 2 pixels each in the left and right edges of each line are cropped from the output.
- Support for generating output to range from 16-bits to 8-bits wide (8-bits wide allows for 50% saving in storage area)
- Support for downsampling via programmable culling patterns
- Ability to control output to the SDRAM via an external write enable signal
- Support for up to 16K pixels (image size) in both the horizontal and vertical direction.

14.1.2 Unsupported Features

The VPFE module does not support the following features.

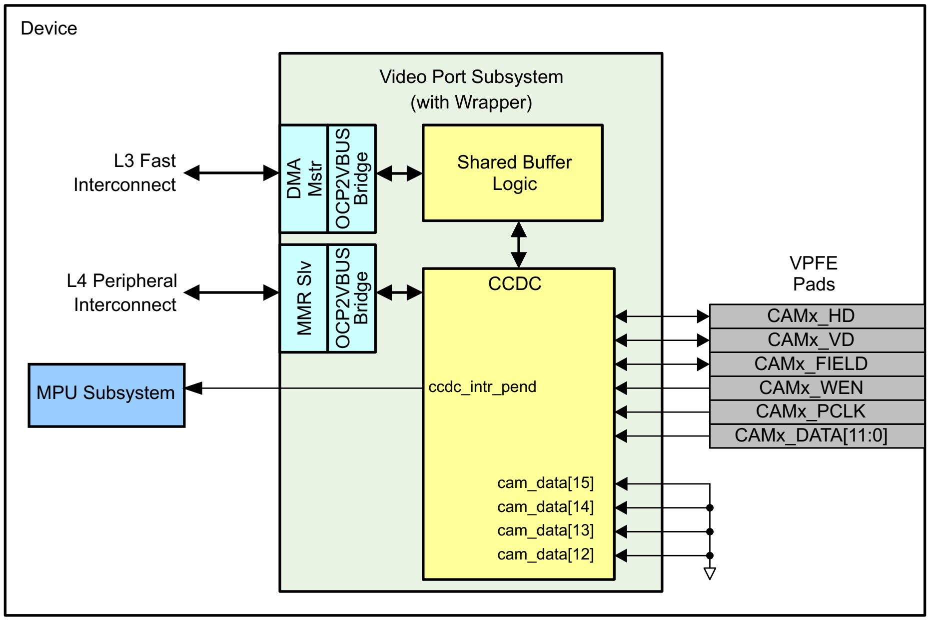
Table 14-1. Unsupported VPFE Features

Feature	Reason
VENC/VPBE Interface	There is no VENC on this device and therefore, Video Encoder direct interface is not connected.
16-bit Input	Only ccdc_data[11:0] pinned out

14.2 Integration

This device includes two instantiations of the Video Port Front End (VPFE) for connection to CCD cameras or BT.656 compliant video encoders.

Figure 14-1. VPFE Integration



14.2.1 VPFE Connectivity Attributes

The general connectivity attributes for the VPFE module are shown in Table 14-2.

Table 14-2. VPFE Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L3_GCLK PD_PER_L3S_GCLK CCDCx_PCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Standby Smart Idle
Interrupt Requests	1 interrupt to MPU Subsystem (CCDCx_INT)
DMA Requests	None
Physical Address	L4 peripheral slave port L3 initiator port

14.2.2 VPFE Clock and Reset Management

The VPFE has separate functional and interface clocks. The pixel clock is supplied from an external pin and is restricted such that ccd_pclk_clk ≤ ½ dma_ocp_clk.

Table 14-3. VPFE Clock Signals

Clock Signal	Maximum Frequency	Reference Source	Comments
mmr_ocp_clk MMR interface clock	100 MHz	CORE_CLKOUTM4	pd_per_l3_gclk from PRCM (divided down using mmr_ocp_clkdiv)
dma_ocp_clk L3 phase clock enable used to create L4 clock	200 MHz	CORE_CLKOUTM4	pd_per_l3_gclk from PRCM
ccd_pclk_clk Functional clock	The lesser of 75 MHz or ½ dma_ocp_clk	CCDCX_PCLK	From external pin

14.2.3 VPFE Pin List

The external pins for the VPFE module are shown in Table 14-4.

Table 14-4. VPFE Pin List

Pin	Type	Description
cam_data[11:0]	I	Camera/VPFE data
cam_hd	I/O	Horizontal sync
cam_vd	I/O	Vertical sync
cam_field	I/O	Field indicator
cam_wen	I	Write enable
cam_pclk	I	Pixel clock

14.3 Functional Description

14.3.1 External IO Interface

The following subsections explain how to connect VPFE signal pins to various input devices.

14.3.1.1 Summary

Table 14-5 summarizes the VPFE signal pins required by common input devices.

Table 14-5. Summary of VPFE Signal Pins and Common Input Devices

Signal Name	I/O	Description	Raw Data Mode 16-bit	Raw Data Mode 8-bit	Raw Data Mode, no Field or WEN 16-bit	Raw Data Mode, no Field or WEN 8-bit	BT.656 Mode 10-bit	BT.656 Mode 8-bit	Digital YCbCr Mode 16-bit	Digital YCbCr Mode 8-bit
cam_hd	I/O	Horizontal sync	+	+	+	+			+	+
cam_vd	I/O	Vertical sync	+	+	+	+			+	+

cam_data11	I	Camera/ VPFE data (bit 11)	+		+				+	

14.3.1.2 Raw Data Mode

Raw data mode is a generic parallel interface that supports up to a 16-bit data path to a CMOS or CCD sensor. The signal interface is described in Table 14-6.

Table 14-6. CCD Interface Signals

Name	I/O	Function
CAM_D[15:0]	I	Image data – A mode set by INPMOD (not R656ON). • Bit width is configurable between 8 and 16 bits (DATSIZ). • The polarity of the input image data is configurable (DATAPOL).
CAM_VD	I	VSYNC - vertical sync signal
CAM_HD	I	HSYNC - horizontal sync signal
CAM_FIELD	I	Field identification signal (optional – FLDMODE) • This signal can be configured to be latched by the VD signal (FIDMD). • The polarity of the field identification signal is configurable (FLDPOL).
CAM_WEN	I	VPFE write enable signal (optional – EXWEN) • The EXWEN signal determines when data is captured, processed, and saved to memory or sent for further processing. • If EXWEN is enabled, image data will be captured, processed, and saved to memory or sent for further processing, depending on the state of WENLOG. • Data can be saved either when CAM_WEN is active and the pixels are within the internal frame (SPH, NPH, SLV, NLV) or when the pixels are within the internal frame (WENLOG).
CAM_PCLK	I	Pixel clock • The PCLK signal is the signal used to latch input image data. • The input image data can be captured on either the rising or on the falling edge of the PCLK signal which is configured by field PCLK_INV. • The maximum pixel clock rate is 75 MHz.

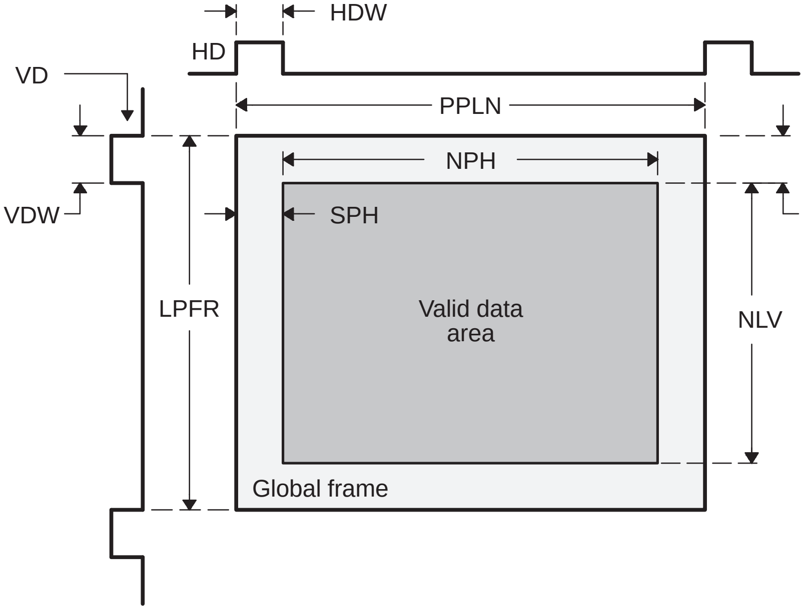
14.3.1.2.1 Mode Information – Always Required

- INPMOD – input mode
- DATSIZ – size (bit width) of input data – always stored in LSBs
- DATAPOL – polarity of input data
- VDPOL – VD polarity
- HDPOL – HD polarity
- FLDMOD – field mode

14.3.1.2.2 Timing Information – Optional, Depending on Control Signals and Sensor Mode

- If FLDMODE is enable
  - FLDPOL – CAM_FIELD polarity
  - FIDMD – CAM_FIELD latch information
- EXWEN – external CAM_WEN signal
  - WENLOG – determines when data is valid along with frame settings

Figure 14-2. CCD Controller Frame and Control Signal Definitions



HDW − Horizontal sync width
HD − Horizontal sync
PPLN − Pixels per line
LPFR − Lines per frame
SPH − Start pixel horizontal
NPH − Size horizontal of valid area
VDW − Veritcal sync width
VD − Vertical sync
OBS − Optical black start
SLVx − Start line vertical field0 or field1
NLV − Size vertical of valid area

14.3.1.3 ITU-R BT.656 Interface

The BT.656 interface supports either 8-bit or 10-bit processing of input video YCbCr data. See Section 14.4 for instructions on how to configure this mode.

Since the data synchronization information is carried along with the data lines, no synchronization signals (i.e., CAM_HD, CAM_VD, and CAM_FIELD) are necessary in this mode.

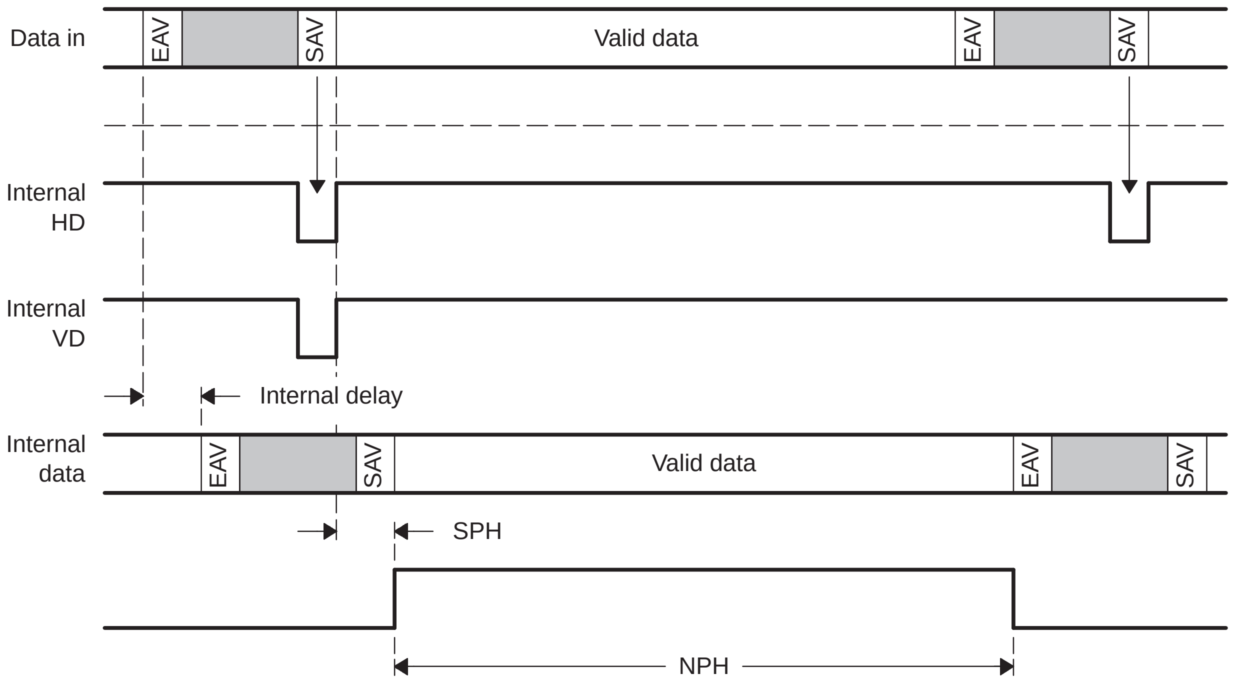
The signal interface is described in Table 14-7.

Table 14-7. ITU-R BT.656 Interface Signals

Name	I/O	Function
CAM_D[9:0]	I	Image data – mode set by R656ON • Bit width is configurable to either eight or ten bits (BW656). • The polarity of the input image data is configurable (DATAPOL).
CAM_PCLK	I	Pixel clock • The PCLK signal is the signal used to latch input image data. • The input image data can be captured on either the rising or on the falling edge of the PCLK signal which is configured by field PCLK_INV. • The maximum pixel clock rate is 75 MHz.

Two timing reference codes are transmitted as the synchronization signal. At the start and end of each video data block, two unique codes are sent, respectively. The start code is called the start of active video signal (SAV), and the end code is called the end of active video signal (EAV). The SAV and EAV codes proceed and follow valid data, as shown in Figure 14-3. The VPFE controller internally bases on SAV and EAV codes to generate the necessary synchronization signals, i.e., horizontal sync, vertical synx, and field ID.

Figure 14-3. BT.656 Signal Interface



Both timing reference signals, SAV and EAV, consist of a four-word sequence in the following format: FF 00 00 XY, where FF 00 00 are a set preamble and the fourth word defines the field identification, the state of vertical field blanking, the state of horizontal line blanking, and protection (error correction) codes. The bit format of the fourth word is shown in Table 14-8 and the definitions for bits, F, V, and H, are given in Table 14-9. F, V, and H are used in place of the usual horizontal sync, vertical sync, and blank timing control signals. Bits P3, P2, P1, and P0 are protection (error correction) bits for F, V, and H. The relationship the between F, V, and H and the protection (error correction) bits is given in Table 14-10. To enable error correction, set the ECCFVH bit in the REC656IF register. The VPFE controller automatically detects and applies error correction when the ECCFVH bit is set.

Table 14-8. Video Timing Reference Codes for SAV and EAV

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9 (MSB)	1	0	0	1
8	1	0	0	F
7	1	0	0	V
6	1	0	0	H
5	1	0	0	P3
4	1	0	0	P2
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

Table 14-9. F, V, H Signal Descriptions

Signal	Value	Command
F	0	Field 1
	1	Field 2
V	0	0
	1	Vertical blank
H	0	SAV
	1	EAV

Table 14-10. F, H, V Protection (error correction) Bits

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

NOTE: The VPFE controller outputs the XY code in the SAV and EAV into the external memory. In order to eliminate this, set the SPH register field to +1. Also set the NPH register field to accurately represent the number of active pixels.

14.3.1.4 Digital YCbCr Interface

The digital YCbCr interface supports either 8-bit or 16-bit devices. The signal interface is described in Table 14-11.

Unlike the BT.656 mode, discrete horizontal sync (CAM_HD) and vertical sync (CAM_VD) signals are required. An NTSC/PAL decoder is an example device that can be connected to the YCbCr interface.

You can use data lines YI[7:0] or CI [7:0] for input in 8-bit mode. Alternately, you can connect two separate devices; however, only one can be active at any given time. Setting the YCINSWP bit in the CCDCFG register determines which set of 8-bit inputs are active.

Use data lines YI [7:0] and CI[7:0] for input in 16-bit mode. Use the YCINSWP bit in the CCDCFG register to swap the Y and Cr/Cb data lines.

Table 14-11. CCD Interface Signals

Name	I/O	Function
CAM_D [15:0] = YI [7:0] / CI [7:0]	I	Image data – mode set by INPMOD (not R656ON) • Bit width is only configurable to either 8 bits or 16 bits (INPMOD). • The polarity of the input image data is reversible (DATAPOL). • When the 16-bit interface is used, you can swap the Y and C inputs (YCINSWP). • When the 8-bit interface is used, you can connect either half of the bus (YCINSWP). • When the 8-bit interface is used, you can set the position of the Y data to either the even or odd pixel (Y8POS).
CAM_VD	I	VSYNC - vertical sync signal
CAM_HD	I	HSYNC - horizontal sync signal
CAM_FIELD	I	Field identification signal (optional – FLDMODE) • This signal can be configured to be latched by the VD signal (FIDMD). • The polarity of the field identification signal is configurable (FLDPOL).
CAM_PCLK	I	Pixel clock • The PCLK signal is the signal used to latch input image data. • The input image data can be captured on either the rising or on the falling edge of the PCLK signal which is configured by field PCLK_INV. • The maximum pixel clock rate is 75 MHz.

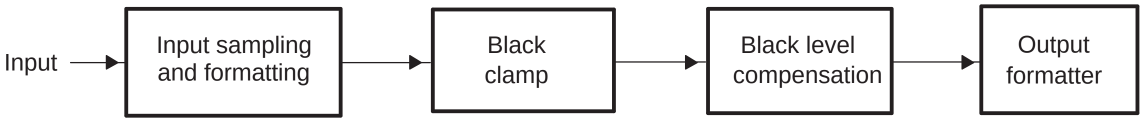
14.3.2 VPFE Data / Image Processing

This section describes the image/data processing of each module in the VPFE in more detail. Section 14.3.2.1 describes the raw data mode while Section 14.3.2.2 explains the YCbCr and BT656 modes.

14.3.2.1 Raw Data Mode

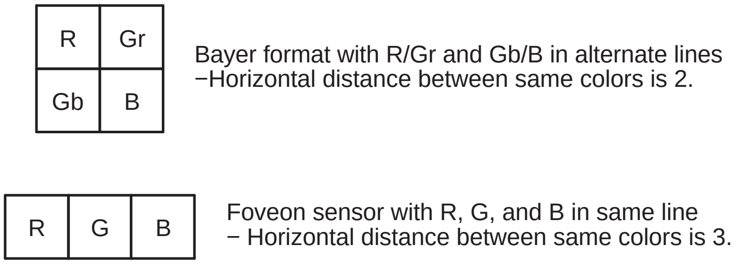
Raw data mode is enabled by setting SYN_MODE.INPMODE to 0 and setting REC656IF.REC656ON to 0. Figure 14-4 shows the corresponding data processing diagram.

Figure 14-4. Data Processing in Raw Data Mode



Typically, raw sensor data is one color per pixel in a color filter array (CFA). The color filter array applied is typically a Bayer pattern, as shown in Figure 14-5 for RGB color space. Alternatively, the special Foveon X3-family sensors capture R, G, and B lights at each pixel location. Both Bayer and Foveon sensors are supported by the VPFE controller.

Figure 14-5. Color Patterns

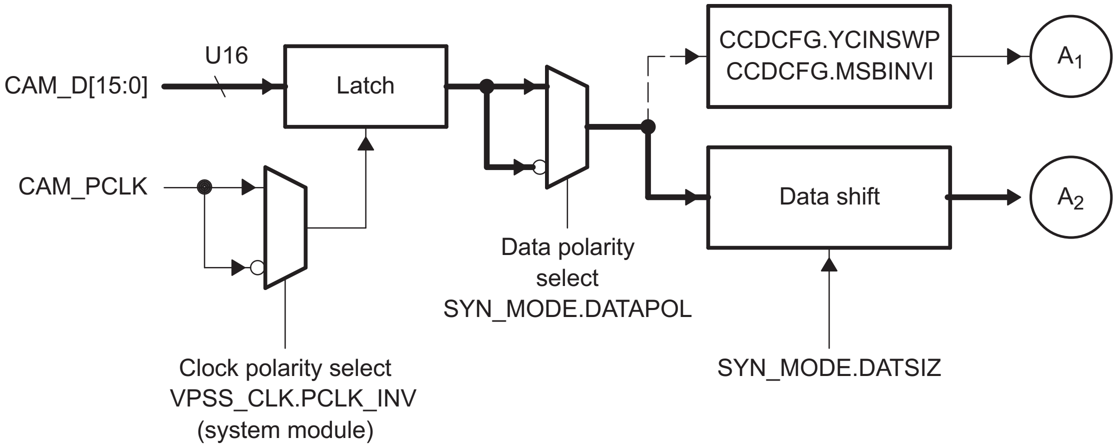


14.3.2.1.1 Input Sampling and Formatting

The data path of raw data mode is shown in the thicker lines in Figure 14-6 (i.e., A2). Data path A1 is applicable to YUV input mode only.

- The pixel clock (CAM_PCLK) latches the data.
- Pixel clock polarity can be either rising or falling edge and is set in VPSS clock control register (VPSS_CLK.PCLK_INV).
- DATAPOL bit in the SYN_MODE register affects the data representation.
- Data is right-shifted to align the data in the least significant bits of the data bus and provide the maximum dynamic range for the remainder of the processing (DATSIZ bit in the SYN_MODE register). This also sets the maximum data size allowed in subsequent clipping/limiting operations and is the output data alignment when it is written to external memory.

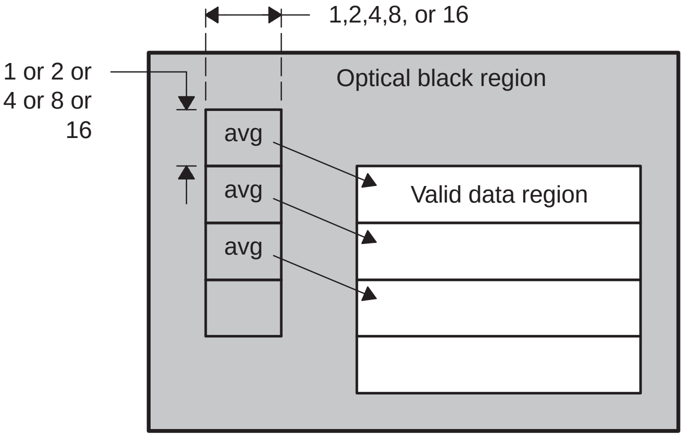
Figure 14-6. Input Formatter



14.3.2.1.2 Optical Black Clamping

Sensor manufacturers typically provide some optically masked pixels at the beginning/end of each line to allow you to determine the noise floor on any given frame of data. The optical black clamping function provides a means to average the optically black pixels and subtract that value from each input pixel as the first step in reducing the noise on the input pixels.

Figure 14-7. Optical Black Averaging & Application

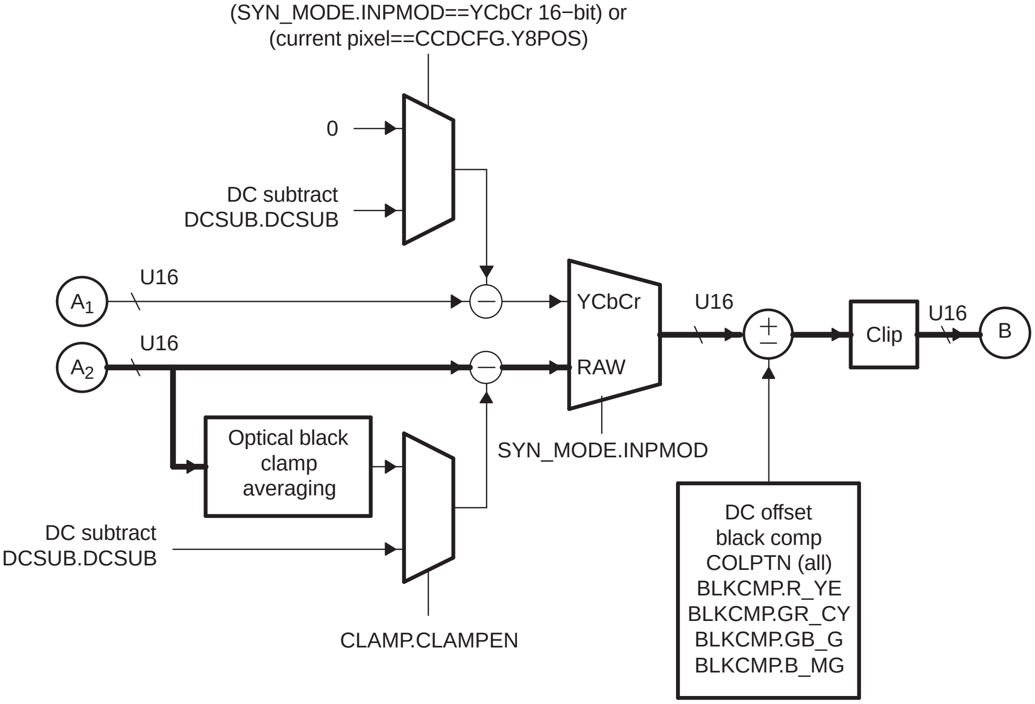


The averaging circuit takes an average of masked (black) pixel values from the image sensor, averaging pixels at the start (OBST bit in the CLAMP register) of each line (OBSLEN bit in the CLAMP register) and for the number of indicated lines (OBSLN bit in the CLAMP register), plus an optional gain adjustment (OBGAIN bit in the CLAMP register). The resultant value is subtracted from the image data at the succeeding line. You can control the position of the black pixels, the number of pixels (8 or 16) in each line that are averaged, and the number of lines (8 or 16) that are averaged.

Alternately, you can disable black clamp averaging (CLAMPEN bit in the CLAMP register) and select a constant black value for subtraction (DCSUB bit in the DCSUB register) instead of using the calculated average value.

The corresponding data path is shown in the thicker lines in Figure 14-8.

Figure 14-8. Black Clamping and Black Level Compensation



14.3.2.1.3 Black Level Compensation

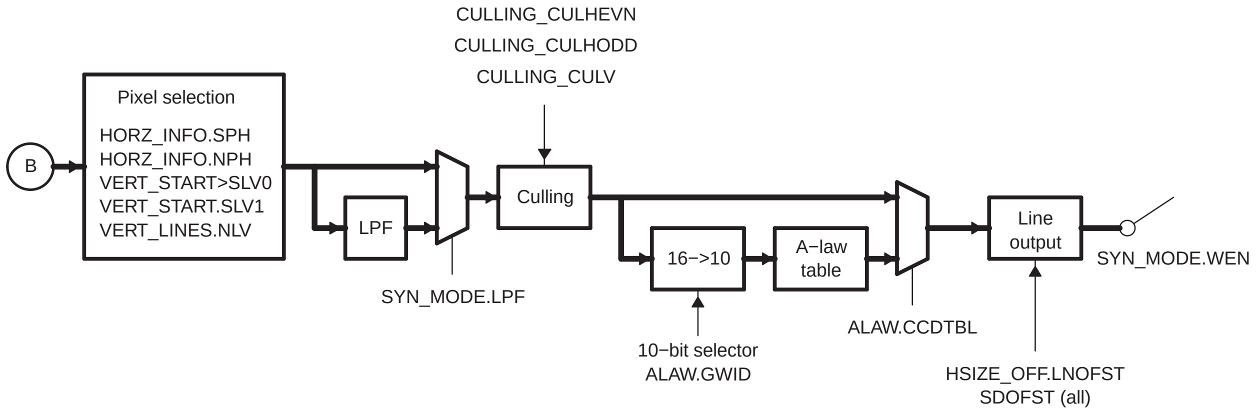
After the digital clamping is applied to the data, black level compensation is applied (Figure 14-8). In this operation, a fixed value is subtracted from the data depending on the color (i.e., R/Ye, Gr/Cy, Gb/G, and B/Mg). The offset (BLKCMP register, fields R_YE, GR_CY, GB_G, B_MG) that is applied to each data sample is selected according to the 0/1/2/3 phase and the color (0/1/2/3) specified for each phase (COLPTN). The color pattern definition is very flexible in order to accommodate many different capture devices, including normal Bayer CFA sampling, Foveon sensors, and VGA movie mode CCDs, whose VGA draft mode output does not follow the typical Bayer pattern.

14.3.2.1.4 Output Formatter

The final stage of VPFE processing is the output formatter, as shown in Figure 14-9. A framing selection is applied to limit the processing area by the settings in the HORZ_INFO, VERT_START and VERT_LINES registers.

NOTE: In addition to the framing applied at the beginning and end of the data formatter operation, you must apply a framing selection to limit the processing area. Please ensure that the settings are relative to that frame.

Figure 14-9. Output Formatter



14.3.2.1.4.1 Low Pass Filter

Use the LPF bit in the SYN_MODE register to apply an optional low-pass filter after the reframing. The low-pass filter consists of a simple 3-tap (¼ , ½ , ¼) filter. Two pixels on the left and two pixels on the right of each line are cropped if the filter is enabled.

14.3.2.1.4.2 Culling

Use the CULEVEN and CULODD bits in the CULLING register (8-bit repeating mask, one per field) to enable an optional culling operation, which culls (deletes) selected pixel data from a line. Use the CULV bit in the CULLING register to select lines from a frame.

Table 14-12 illustrates how the register values apply the decimation pattern to the data. The pixels in white will be saved to external memory and the shaded pixels are discarded.

In this case:

- CULLING = 0x59C40066, with
- CULHEVN = 0x59,
- CULHODD = 0xC4, and
- CULV = 0x66.

Table 14-12. Example for Decimation Pattern

		LSB							
	CULHEVN	0	0	1	0	0	0	1	1	
	CULHODD	1	0	0	1	1	0	1	0	0
0th line		▨	▨	▨	▨	▨	▨	▨	▨	1
1st line			▨	▨			▨		▨	1
2nd line		▨	▨		▨	▨	▨			0
3rd line		▨	▨	▨	▨	▨	▨	▨	▨	0
4th line		▨	▨	▨	▨	▨	▨	▨	▨	1
5th line			▨	▨			▨		▨	1
6th line		▨	▨		▨	▨	▨			0
7th line		▨	▨	▨	▨	▨	▨	▨	▨	CULV

14.3.2.1.4.3 A-Law Transformation

Use the CCDTBL bit in the ALAW register to apply an optional 10-to-8-bit A-Law transformation using a fixed A-Law table as the final processing stage. Using this causes the data width to reduce to 8 bits and allows packing to 8 bits/pixel when saving to external memory. Since the data resolution can be greater than 10 bits at this stage, you must select the 10 bits for input to the A-Law operation. Use the GWID bit in the ALAW register to select the 10 bits for input.

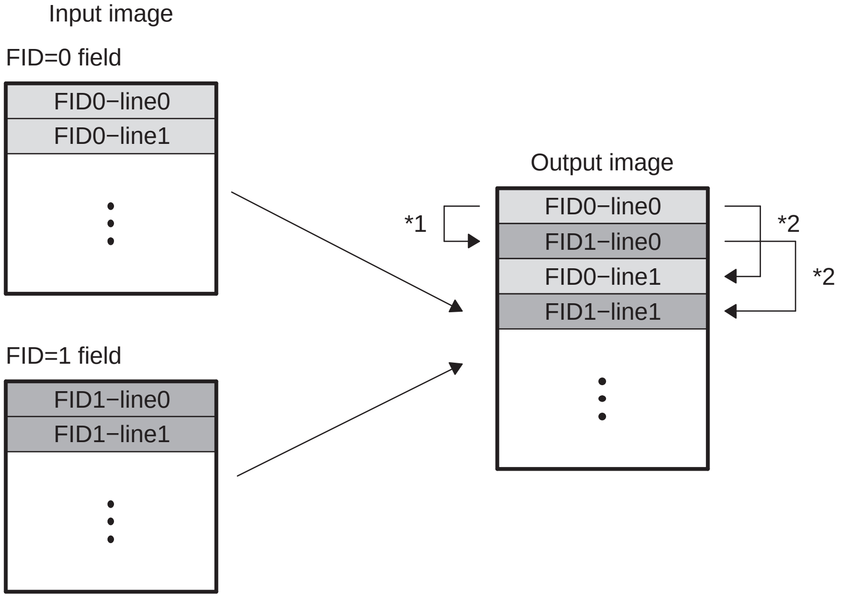
14.3.2.1.4.4 Line Output Control

The final stage of the raw data mode is the line output control, which controls how the input sensor lines are written to external memory. The value of the ADR bit in the SDR_ADDR register defines the starting address where the frame should be written in external memory. The value of the LNOFST bit in the HSIZE_OFF register defines the distance between the beginning of output lines in bytes. Both the starting address and line offset must be aligned to 32-byte boundaries (i.e., either 16 or 32 pixels, depending on the PACK8 bit in the SYN_MODE register). Use the SDOFST register to define additional offsets, depending on the field ID and the even/odd line numbers. Defining additional offsets provides a means to de-interlace an interlaced, two-field input and also inverts an input image vertically. See Figure 14-11 and Figure 14-12 for example usage.

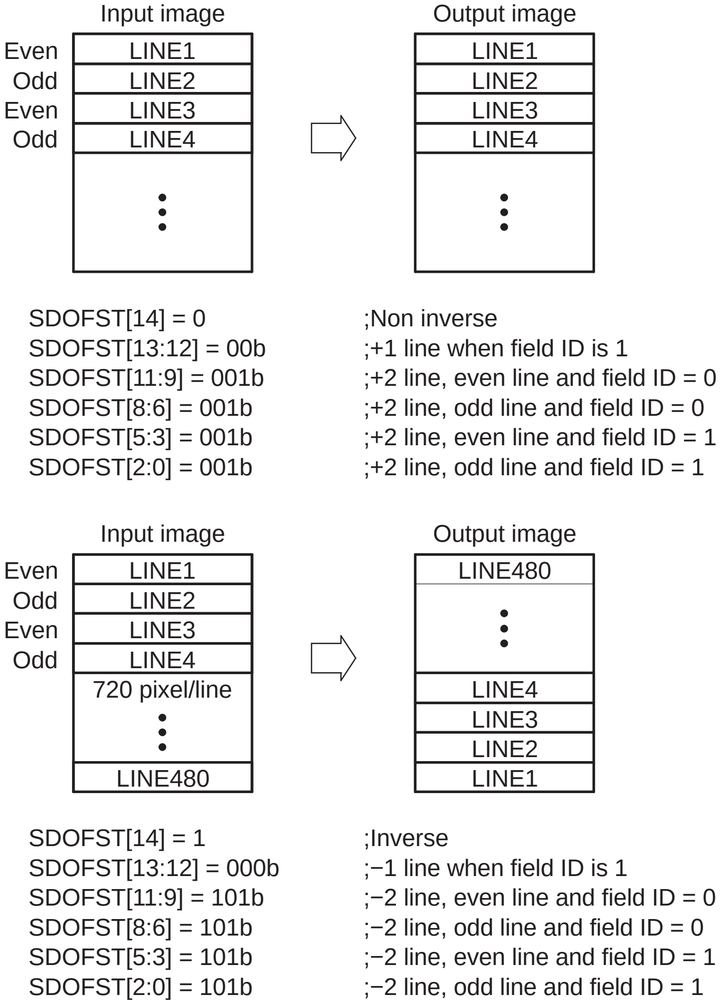
Figure 14-11. Image De-interfacing



*1 − SDOFST[13:12]=00b, +1 line for FID=1 lines

*2 − SDOFST[11:9]=SDOFST[8:6]=SDOFST[5:3]=SDOFST[2:0]=001b, +2 lines

Figure 14-12. Non-inversed vs Inversed Format



```
SDOFST[14] = 0            ;Non inverse
SDOFST[13:12] = 00b       ;+1 line when field ID is 1
SDOFST[11:9] = 001b       ;+2 line, even line and field ID = 0
SDOFST[8:6] = 001b        ;+2 line, odd line and field ID = 0
SDOFST[5:3] = 001b        ;+2 line, even line and field ID = 1
SDOFST[2:0] = 001b        ;+2 line, odd line and field ID = 1
```

```
SDOFST[14] = 1            ;Inverse
SDOFST[13:12] = 000b      ;−1 line when field ID is 1
SDOFST[11:9] = 101b       ;−2 line, even line and field ID = 0
SDOFST[8:6] = 101b        ;−2 line, odd line and field ID = 0
SDOFST[5:3] = 101b        ;−2 line, even line and field ID = 1
SDOFST[2:0] = 101b        ;−2 line, odd line and field ID = 1
```

14.3.2.1.4.5 Output Format

The pixel data format in external memory is shown in Table 14-16.

- If pixel data format is 8-bit, every 16-bit word in external memory stores two pixel data.
- If pixel data format is greater than 8-bit, every 16-bit word in external memory stores one pixel data, and the unused bits are MSB which are filled with 0.

Table 14-15. Storage Format in external memory for Raw Data Mode

	Upper Word		Lower Word	
	MSB (31)	LSB (16)	MSB (15)	LSB (0)
16-bit		Pixel1		Pixel0
15-bit	0	Pixel1	0	Pixel0
14-bit	0	Pixel1	0	Pixel0
13-bit	0	Pixel1	0	Pixel0
12-bit	0	Pixel1	0	Pixel0
11-bit	0	Pixel1	0	Pixel0
10-bit	0	Pixel1	0	Pixel0
9-bit	0	Pixel1	0	Pixel0
8-bit	0	Pixel1	0	Pixel0
8-bit pack	Pixel3	Pixel2	Pixel1	Pixel0

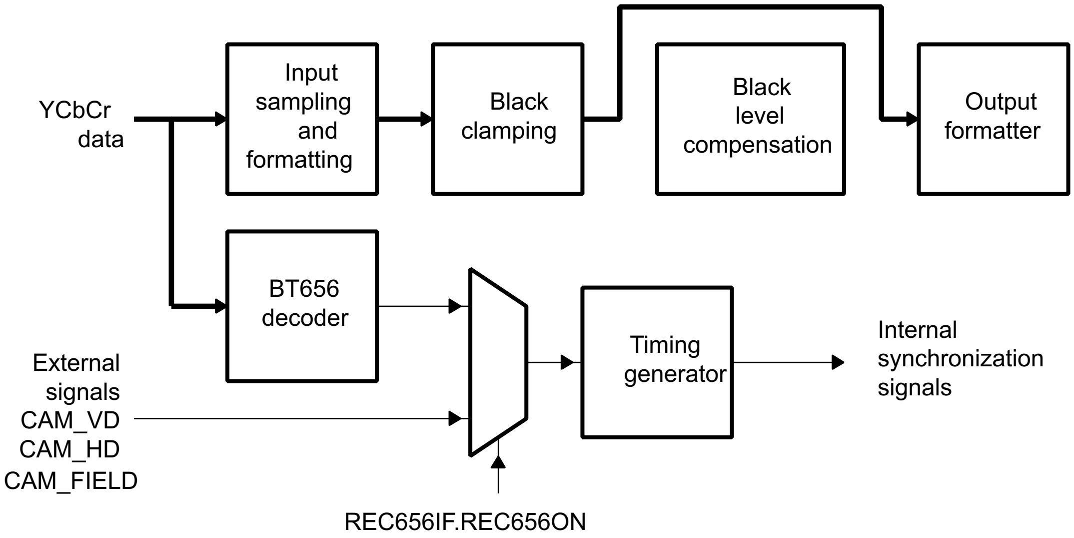
14.3.2.2 YCbCr and BT656 Modes

YCbCr mode and BT656 mode are similar in operation, as shown in Figure 14-13. The additional logic used in BT656 mode is the CCIR656 decoder, which extracts synchronization information from input YCbCr data and regenerates the corresponding timing for internal operation.

- YCbCr mode is enabled by setting field INPMODE in register SYN_MODE to 1 or 2 and clearing field REC656ON in register REC656IF.
- BT656 mode is enabled by setting REC656ON in register REC656IF to 1.

YCbCr mode typically has 8 bits per luma/choma sample while BT656 mode has 8 bits or 10 bits per luma/chroma sample.

Figure 14-13. Data Processing in YUV/BT656 Modes

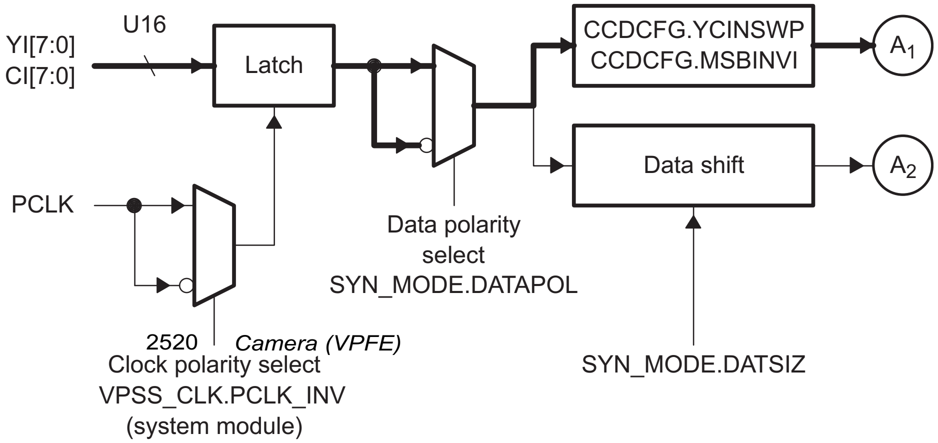


14.3.2.2.1 Input Sampling and Formatting

The data path of YCbCr/BT656 modes is shown in thicker lines in Figure 14-14 (i.e., A1). Data path A2 is applicable to raw data mode only.

- The pixel clock (CAM_PCLK) latches data.
- Pixel clock polarity can be either rising or falling edge and is set in VPSS clock control register (VPSS_CLK.PCLK_INV).
- DATAPOL bit in the SYN_MODE register affects the data representation.
- Bit YCINSWP in register CCDCFG can be used to swap the upper and lower portions of the 16-bit YCbCr data bus.
  - In 16-bit YCbCr mode, this swap bit determines which part of the bus luma and chroma samples occupy respectively.
  - In 8-bit mode, this swap bit determines which part of the bus is the effective 8-bit input. In other words, two external 8-bit YCbCr capture devices can be tied to VPFE module directly.
- Bit MSBINVI in register CCDCFG can be used to invert the MSB of the chroma signal.

Figure 14-14. CCD Controller

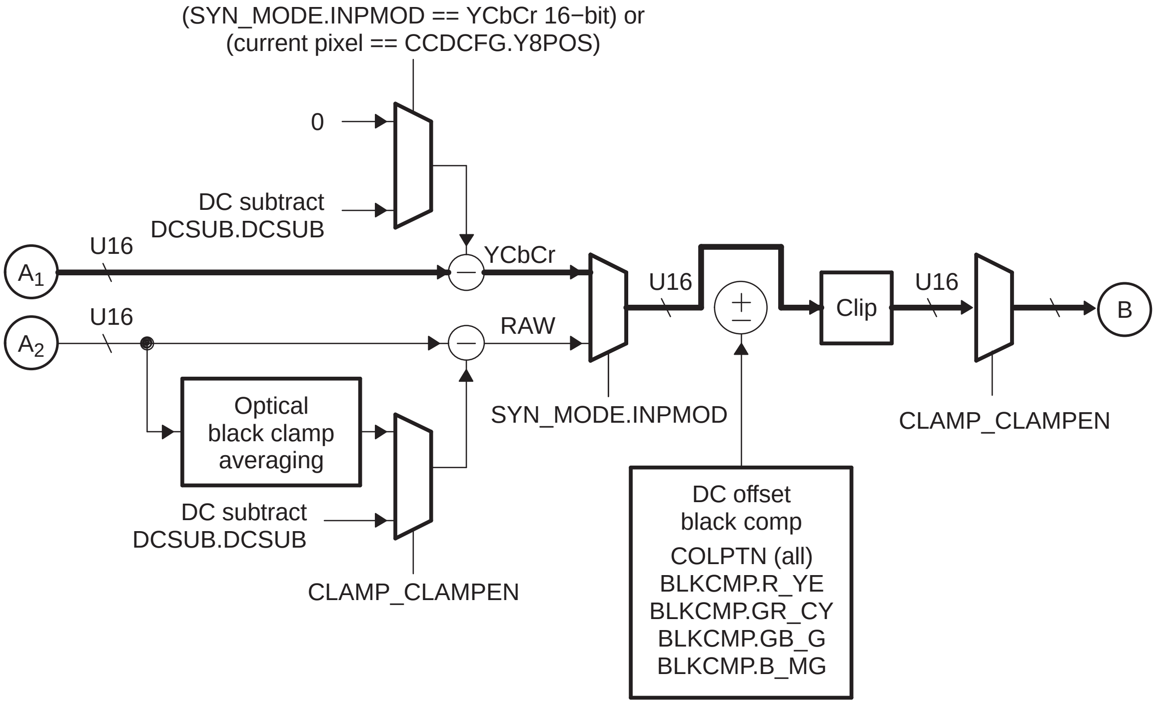


14.3.2.2.2 Black Clamping

The second step in BT.656/YCbCr processing is black clamping

Use the DCSUB bit in the DCSUB register to subtract a fixed value from the luma sample for YUV data. Set the subtraction value to zero to disable the operation. See Figure 14-15 for more details. You may notice that black compensation (BLKCMP) is not used in YCbCr and BT656 modes.

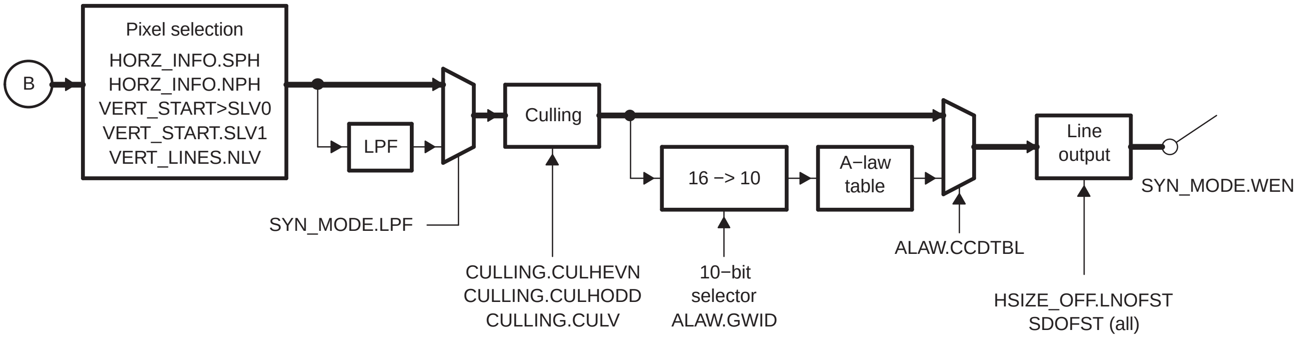
Figure 14-15. Black Clamping and Block Level Compensation



14.3.2.2.3 Output Formatter

The output formatter is the final stage of VPFE processing (as shown as thicker lines in Figure 14-16). Apply a framing selection to limit the processing area by the settings in the HORZ_INFO, VERT_START and VERT_LINES registers.

Figure 14-16. Output Formatter



- Use the LFP bit in the SYN_MODE register to disable the LPF by setting the LFP bit equal to 0.
- Culling can be used in YCbCr and BT656 modes; however, care must be taken to preserve the 422 output format.
- Do not use the A-Law transformation in YCbCr or BT.656 mode (the CCDTBL bit in the ALAW register = 0).

The pixel data in external memory is shown in Table 14-16.

Table 14-16. Storage Format in external memory for BT.656/YCbCr Modes

external memory Address	Upper word		Lower word	
	MSB (31)	LSB (16)	MSB (15)	LSB (0)
N	Y1	Cr0	Y0	Cb0
N + 1	Y3	Cr2	Y2	Cb2
N + 2	Y5	Cr4	Y4	Cb4

14.4 Programming Model

The following programming procedures should be followed to enable the VPFE controller to receive video or image capture data.

1. Power-up the VPFE using the Power, Reset, and Clock Management (PRCM) module.
2. Disable the VPFE controller.
3. Configure the VPFE registers to match the system requirements, including interrupt setup.
4. Enable the VPFE controller.

Once the VPFE controller is enabled, it starts to process input data continuously. No user intervention is necessary to re-start the process. As a result, the VPFE interrupt must be set up correctly in order to operate properly. Users can terminate its operation by disabling the VPFE controller.

The remaining sections describe the programming procedure in more detail.

14.4.1 Enabling and Disabling the VPFE Controller

The following steps describe how to enable and disable the VPFE controller:

- Clearing the ENABLE bit in the VPFE_PCR register disables the VPFE controller.
- Setting the ENABLE bit in the VPFE_PCR register enables the VPFE controller.
  - The VPFE controller should be enabled prior to data transmission from the external device to avoid data loss.

14.4.2 Configuring VPFE Registers

14.4.2.1 General Register Setup

Table 14-17 lists the minimum register fields that must be configured.

Table 14-17. Basic Configuration of VPFE Registers

Function	Register	Fields
External signal configuration (This includes signals CAM_VD, CAM_HD, CAM_FIELD, and CAM_WEN.)	SYN_MODE	VDHDEN VDPOL HDPOL FLDMODE FLDPOL EXWEN DATAPOL
	CCDCFG	VDLC
Input data mode	REC656	R656ON
	SYN_MODE	INPMOD
Color pattern	COLPTN	All
Black compensation	BLKCMP	All
Data path configuration	SYN_MODE	WEN

Table 14-18 describes additional configuration requirements when certain conditions are met.

Table 14-18. Conditional Configuration of VPFE Registers

Category	If...	Then program...
Interlace mode	Field FLDMODE in register SYN_MODE is 1	Field FIDMD in register CCDCFG
External WEN	Field EXWEN in register SYN_MODE is 1	Field WENLOG bit in register CCDCFG
REC656 input	Field R656ON in register REC656 is 1	Field ECCFVH in register REC656 Field BW656 in register CCDCFG
RAW input	Field INPMOD in register SYN_MODE is 0 and Field R656ON in register REC656 is 1	Field DATSIZ in register SYN_MODE Field CLAMPEN in register CLAMP
16-bit YCC input	Field INPMOD in register SYN_MODE is 1 and Field R656ON in register REC656 is 1	Field YCINSWP in register CCDCFG Field MSBINVI in register CCDCFG Register DCSUB
8-bit YCC input	Field INPMOD in register SYN_MODE is 2 and Field R656ON in register REC656 is 1	Field Y8POS in register CCDCFG
Optical black clamp enabled	Field CLAMPEN in register CLAMP is 1 and Field INPMOD in register SYN_MODE is 0	Field OBGAIN in register CLAMP Field OBST in register CLAMP Field OBSLN in register CLAMP Field OBSLEN in register CLAMP
Optical black clamp disabled	Field CLAMPEN in register CLAMP is 0 and Field INPMOD in register SYN_MODE is 0	Register DCSUB
Write to external memory	Field WEN in register SYN_MODE is 1	Field LPF in register SYN_MODE Field PACK8 in register SYN_MODE Field CCDTBL in register ALAW Field BSWD in register CCDCFG Register HORZ_INFO Register VERT_START Register VERT_LINES Register CULLING Register SDR_ADDR Register HSIZE_OFF Register SDOFST
A-law	Field CCDTBL in register ALAW is 1	Field GWID in register ALAW
Interrupt	Interrupts CCDC_VD0_INT and CCDC_VD1_INT are to be used	Register VDINT

14.4.2.2 Interrupts

The VPFE controller can generate three interrupts: CCDC_VD0_INT, CCDC_VD1_INT, and CCDC_VD2_INT.

NOTE: Enable the VDHDEN field in register SYN_MODE to receive any of these VPFE controller interrupts.

The CCDC_VD0_INT and CCDC_VD1_INT interrupts occur relative to the VD pulse, as shown in Figure 14-17 and Figure 14-18. Please note that field VDPOL in register SYN_MODE changes the trigger timing.

- If field VDPOL is 1, the VDINT0 and VDINT1 counters begin counting CAM_HD pulses from the falling edge of signal CAM_VD.
- If field VDPOL is 0, the VDINT0 and VDINT1 counters begin counting CAM_HD pulses from the rising edge of signal CAM_VD.

- Interrupts CCDC_VD0_INT and CCDC_VD1_INT occur after receiving the number of horizontal lines (CAM_HD pulse signals) set in the VDINT0 bit in the VDINT register and the VDINT1 bit in the VDINT register, respectively.

Figure 14-17. VDPOL is 0

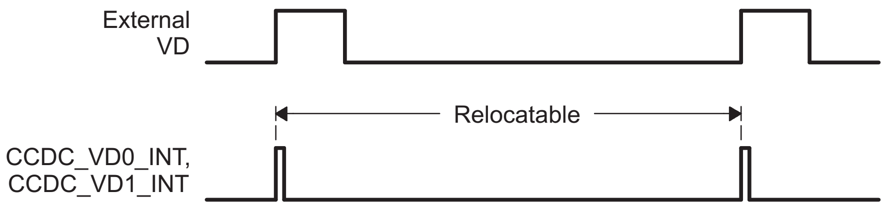


Figure 14-18. VDPOL is 1

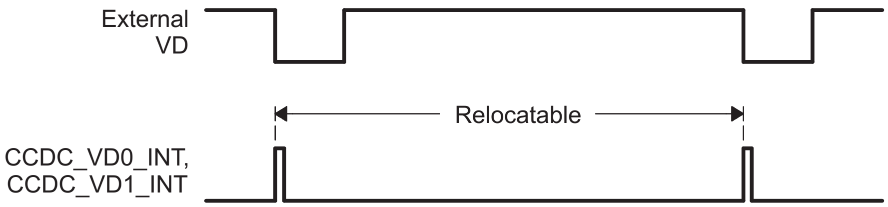
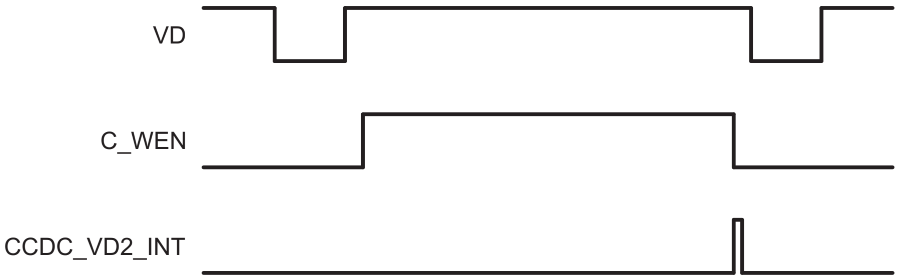


The CCDC_VD2_INT interrupt always occurs at the falling edge of the CAM_WEN signal (via an external pin), as shown in Figure 14-19. There are no registers in the VPFE module to configure this interrupt.

Figure 14-19. CCDC_VD2_INT Interrupt



14.4.2.3 Status

The BUSY status bit in the VPFE_PCR register is set when the start of frame occurs (if the ENABLE bit in the VPFE_PCR register is 1 at that time). It automatically resets to 0 at the end of a frame.

14.4.2.4 CAM_VD latched Registers

The VDLC field in register CCDCFG affects the access of the following registers and register fields.

Registers
VPFE_PCR
HORZ_INFO
VERT_START
VERT_LINES
CULLING
HSIZE_OFF
SDOFST
SDR_ADDR
Register Fields
WEN in SYN_MODE
LPF in SYN_MODE

Registers
CLAMPEN in CLAMP
YCINSWP in CCDCFG

NOTE:

1. If the VDLC field is 0, changes to the above registers/register fields will take effect immediately.
2. If the VDLC field is 1, changes to the above registers/register fields will take effect at the start of a new frame (i.e., the changes are latched by the CAM_VD signal). Reads from these registers/register fields will return the most recent write value (even though these values may not take effect).

Be careful to avoid undesired effects when using the first approach.

14.4.2.5 Inter-frame Operations

As described in the previous section, the VPFE_PCR and SDR_ADDR registers will be latched by the CAM_VD signal if the VDLC field in the CCDCFG register is 0. This important feature provides a reliable way for programmers to enable/disable the VPFE module and/or modify the memory pointers in-between frames. For example, the VPFE interrupt service routine (ISR) can program the SDR_ADDR register to a new value before the end of the current frame. By doing so, the current frame is received without any interruption and the new external memory address (SDR_ADDR register) will be used for receiving the next frame.

14.4.3 VPFE Limitations

The major limitations of the VPFE module are summarized as follows:

- The CAM_PCLK (pixel clock) signal cannot be higher than 75 MHz.
- The SDR_ADDR and HSIZE_OFF registers should be programmed to values with 5 LBS bits as 0; namely, the memory space they point to should be on a 32-byte boundary.
- The COLPTN register should be set to 0 in YCbCr and BT.656 modes.
- The BLKCMP register should be set to 0 in YCbCr and BT.656 modes.
- Low-pass filter (LPF field in SYN_MODE register) should be disabled in YCbCr and BT.656 modes.
- A-LAW should be disabled in YCbCr and BT.656 modes.

14.5 Registers

14.5.1 VPFE Registers

Table 14-19 lists the memory-mapped registers for the VPFE. All register offset addresses not listed in Table 14-19 should be considered as reserved locations and the register contents should not be modified.

Table 14-19. VPFE Registers

Offset	Acronym	Register Name	Section
0h	VPFE_REVISION		Section 14.5.1.1

Table 14-23. VPFE_HD_VD_WID Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	RESERVED	R		
27-16	HDW	R/W		Width of HD sync pulse if output HDW+1 pixel clocks HDWIDTH is not used when HD is input, i.e when VDHDOUT in SYN_MODE register is cleared to '0' *This bit field is latched by VD
15-12	RESERVED	R		
11-0	VDW	R/W		Width of VD sync pulse if output VDW+1 lines VDWIDTH is not used when VD is input, i.e when VDHDOUT in SYN_MODE register is cleared to '0' *This bit field is latched by VD

14.5.1.5 VPFE_PIX_LINES Register (Offset = 10h) [reset = 0h]

VPFE_PIX_LINES is shown in Figure 14-24 and described in Table 14-24.

Return to Summary Table.

Number of pixels in a horizontal line and number of lines in a frame

Figure 14-24. VPFE_PIX_LINES Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PPLN																HLPFR															
R/W-0h																R/W-0h															

Table 14-24. VPFE_PIX_LINES Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	PPLN	R/W	0h	Pixels per line - number of pixel clock periods in one line HD period = PPLN+1 pixel clocks PPLN is not used when HD and VD are inputs, i.e when VDHDOUT in SYN_MODE register is cleared to '0' *This bit field is latched by VD
15-0	HLPFR	R/W	0h	Half lines per field or frame - sets number of half lines per frame or field VD period = (HLPFR+1)/2 lines HLPFR is not used when HD and VD are inputs, i.e when VDHDOUT in SYN_MODE register is cleared to '0' This tells the internal timing generator to generate the sufficient number of HD pulses in between two VD pulses. If the sensor is an interlaced sensor, say for example, with a total of 525 (or 526) lines, then this field should be set to 525 (or 526). This means that 525 (or 526) half lines are written for each field. If the sensor is progressive, then this register should be set to be twice the number of lines to be written. For example, if sensor outputs 1024 lines, this field should be set to 2048. Therefore, for interlaced sensors, this field should be set to the total number of lines. For progressive sensors, this field should be set to twice the total number of lines. *This bit field is latched by VD

14.5.1.6 VPFE_HORZ_INFO Register (Offset = 14h) [reset = 0h]

VPFE_HORZ_INFO is shown in Figure 14-25 and described in Table 14-25.

Return to Summary Table.

Horizontal Pixel Information Register

Chapter 15

Ethernet Subsystem

This chapter describes the ethernet subsystem of the device.

NOTE: The CPSW is not supported for the AMIC120.

Topic **Page**

15.1 Introduction

Described in the following sections is the Layer 2 3-port switch (3PSW) Ethernet subsystem. The 3-port switch gigabit ethernet subsystem provides ethernet packet communication and can be configured as an ethernet switch. It provides the gigabit media independent interface (GMII),reduced gigabit media independent interface (RGMII), reduced media independent interface (RMII), the management data input output (MDIO) for physical layer device (PHY) management.

As a Layer 2 switch, this device is capable of supporting all higher layers and various protocols, such as IPV4, IPV6, and 802.3x, in software.

15.1.1 Features

The general features of the ethernet switch subsystem are:

- Two 10/100/1000 Ethernet ports with GMII, RMII and RGMII interfaces
- Wire rate switching (802.1d)
- Non Blocking switch fabric
- Flexible logical FIFO based packet buffer structure
- Four priority level QOS support (802.1p)
- CPPI 3.1 compliant DMA controllers
- Support for IEEE 1588v2 Clock Synchronization (2008 Annex D, E, and F)
  - Timing FIFO and time stamping logic inside the SS
- Device Level Ring (DLR) Support
- Address Lookup Engine
  - 1024 addresses plus VLANs
  - Wire rate lookup
  - VLAN support
  - Host controlled time-based aging
  - Spanning tree support
  - L2 address lock and L2 filtering support
  - MAC authentication (802.1x)
  - Receive or destination based Multicast and Broadcast limits
  - MAC address blocking
  - Source port locking
  - OUI host accept/deny feature
- Flow Control Support (802.3x)
- EtherStats and 802.3Stats RMON statistics gathering (shared)
- Support for external packet dropping engine
- CPGMAC_SL transmit to CPGMAC_SL receive Loopback mode (digital loopback) supported
- CPGMAC_SL receive to CPGMAC_SL transmit Loobback mode (FIFO loopback) supported
- Maximum frame size 2016 bytes (2020 with VLAN)
- 8k (2048 x 32) internal CPPI buffer descriptor memory
- MDIO module for PHY Management
- Programmable interrupt control with selected interrupt pacing
- Emulation Support.
- Programmable transmit Inter-Packet Gap (IPG)
- Reset isolation

15.1.2 Unsupported Features

There are 18 level interrupts from the CPGMAC module and 2 (used) level interrupts from the MDIO module. The CPSW_3GSS includes an interrupt combiner/pacer to combine these interrupts together to produce 4 interrupt outputs (per processing core). This device does not split processing among multiple cores but allows servicing of the Core0 interrupts by the Cortex-A9 or the PRU-ICSS.

The unsupported CPGMAC features in the device are shown in the following table.

Table 15-1. Unsupported CPGMAC Features

Feature	Reason
GMII	Only 4 Rx/Tx data pins are pinned out for each port. The device supports MII (on GMII interface), RGMII, and RMII interfaces only
Phy link status	The MLINK inputs are not pinned out. Phy link status outputs can be connected to device GPIOs.
Internal Delay mode for RGMII	RGMII Internal Delay mode is not supported.

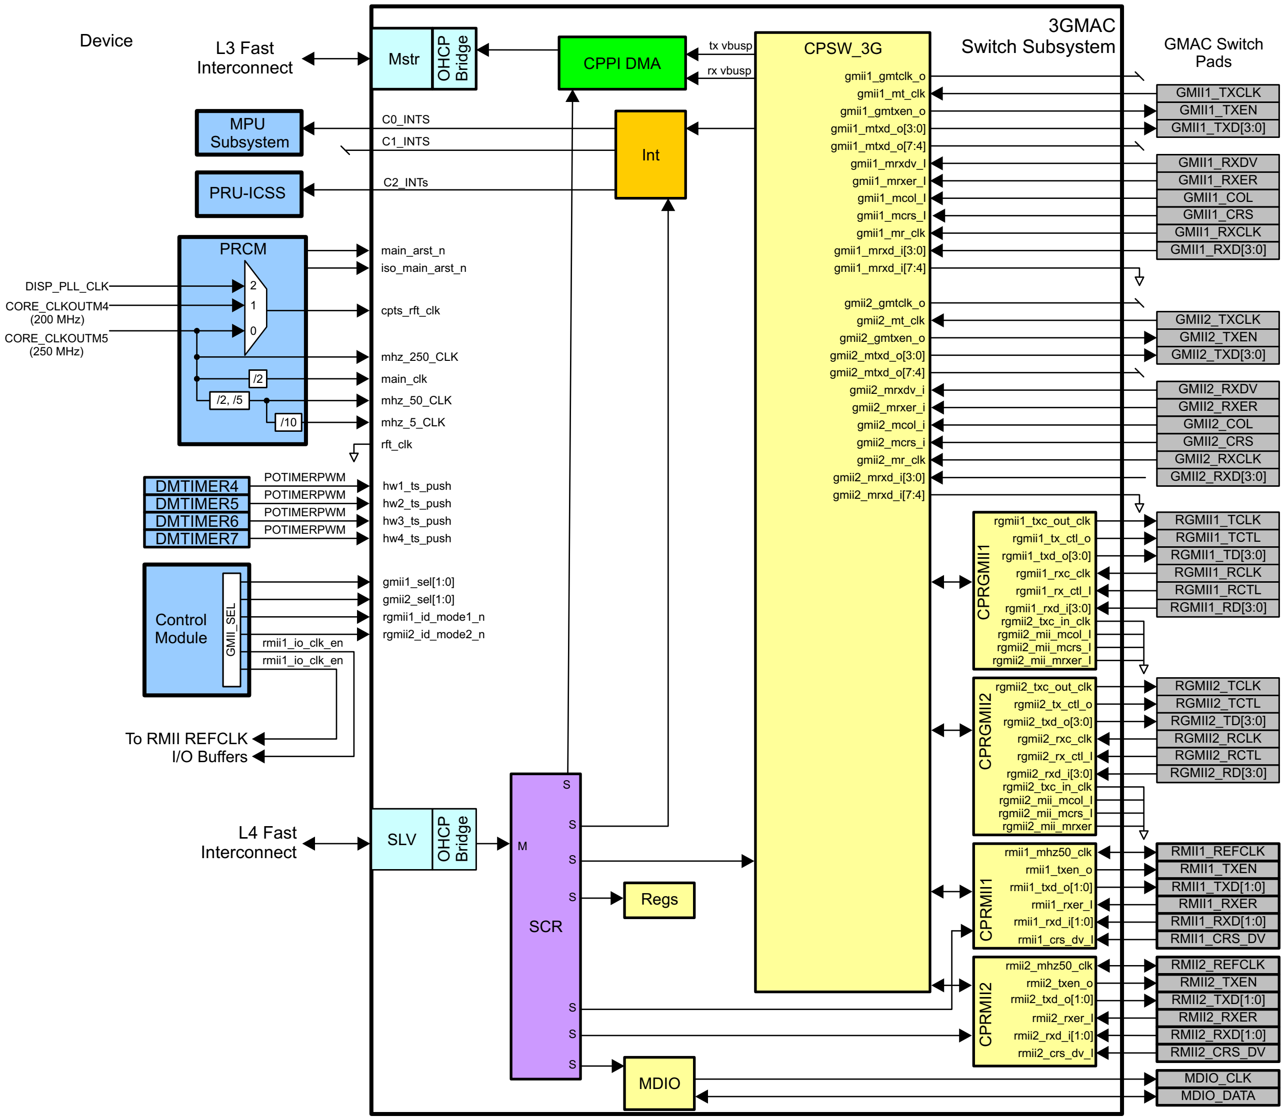
15.2 Integration

This device includes a single instantiation of the three-port Gigabit Ethernet Switch Subsystem (CPSW_3GSS_RG). The switch provides 2 external ethernet ports (ports 1 and 2) and an internal CPPI interface port (port 0) with IEEE 1588v2 and 802.1ae support. The subsystem consists of:

- One instance of the 3-port Gigabit switch CPSW-3G, which contains:
  - 2 CPGMAC_SL 10/100/1000 ethernet port modules with GMII interface
- Two RGMII interface modules
- Two RMII interface modules
- One MDIO interface module
- One Interrupt Controller module
- Local CPPI memory of size 8K Bytes

The integration of the Ethernet Switch is shown in Figure 15-1

Figure 15-1. Ethernet Switch Integration



15.2.1 Ethernet Switch Connectivity Attributes

The general connectivity attributes for the Ethernet Switch module are shown in Table 15-2.

Table 15-2. Ethernet Switch Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_CPSW_125MHZ_GCLK (Main) PD_PER_CPSW_250MHZ_GCLK (MHZ_250_CLK) PD_PER_CPSW_50MHZ_GCLK (MHZ_50_CLK) PD_PER_CPSW_5MHZ_GCLK (MHZ_5_CLK) PD_PER_CPSW_CPTS_RFT_CLK (CPTS_RFT_CLK)
Reset Signals	CPSW_MAIN_ARST_N CPSW_ISO_MAIN_ARST_N
Idle/Wakeup Signals	Smart Idle Standby
Interrupt Requests	Three sets of 4 Interrupts RX_THRESH (3PGSWRXTHR0) – Receive Threshold interrupt (nonpaced) RX (3PGSWRXINT0) – Receive interrupt (paced) TX (3PGSWTXINT0) – Transmit interrupt (paced) Misc (3PGSWMISC0) – Other interrupts The Subsystem contains 3 sets of interrupts—C0, C1, and C2—to allow for split core processing of packets. On this device, the C0 version of the interrupts is used for the MPU Subsystem, the C1 version is unused, and the C2 version is used for PRU-ICSS.
DMA Requests	None
Physical Address	L4 Fast slave port L3 Fast initiator port

15.2.2 Ethernet Switch Clock and Reset Management

The ethernet switch controller operates in its own clock domain and its initiator and target interfaces are connected to the L3/L4 through asynchronous bridges. The OCP interfaces are driven by the MAIN clock input. Additional reference clock inputs are provided for operating the various ethernet ports at different rates.

Table 15-3. Ethernet Switch Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
rft_clk Gigabit GMII Tx Reference clock	125 MHz	Tied low	not supported
main_clk Logic/Interface clock	125 MHz	CORE_CLKOUTM5 / 2	pd_per_cpsw_125mhz_gclk from PRCM
mhz250_clk Gigabit RGMII Reference clock	250 MHz	CORE_CLKOUTM5	pd_per_cpsw_250mhz_gclk from PRCM
mhz50_clk RMII and 100mbps RGMII Reference clock	50 MHz	CORE_CLKOUTM5 / 5	pd_per_cpsw_50mhz_gclk from PRCM
mhz5_clk 10 mbpsRGMII Reference clock	5 MHz	CORE_CLKOUTM5 / 50	pd_per_cpsw_5mhz_gclk from PRCM
cpts_rft_clk IEEE 1588v2 clock	250 MHz	CORE_CLKOUTM4 CORE_CLKOUTM5 Display PLL CLKOUT	pd_per_cpsw_cpts_rft_clk from PRCM
gmii1_mr_clk GMII Port 1 Receive clock	25 MHz	External Pin	gmii1_rxclk_in from GMII1_RCLK pad
gmii2_mr_clk GMII Port 2 Receive clock	25 MHz	External Pin	gmii2_rxclk_in from GMII2_RCLK pad
gmii1_mt_clk GMII Port 1 Transmit clock	25 MHz	External Pin	gmii1_txclk_in from GMII1_TCLK pad
gmii2_mt_clk GMII Port 2 Transmit clock	25 MHz	External Pin	gmii2_txclk_in from GMII2_TCLK pad
rgmii1_rxc_clk RGMII Port 1 Receive clock	250 MHz	External Pin	rgmii1_rclk_in from RGMII1_RCLK pad
rgmii2_rxc_clk RGMII Port 2 Receive clock	250 MHz	External Pin	rgmii2_rclk_in from RGMII2_RCLK pad
rmii1_mhz_50_clk RMII Port 1 Reference clock	50 MHz	External Pin	rmii1_refclk_in from RMII1_REFCLK pad
rmii2_mhz_50_clk RMII Port 2 Reference clock	50 MHz	External Pin	rmii2_refclk_in from RMII2_REFCLK pad

15.2.3 Ethernet Switch Pin List

The external signals for the Ethernet Switch module are shown in the following table.

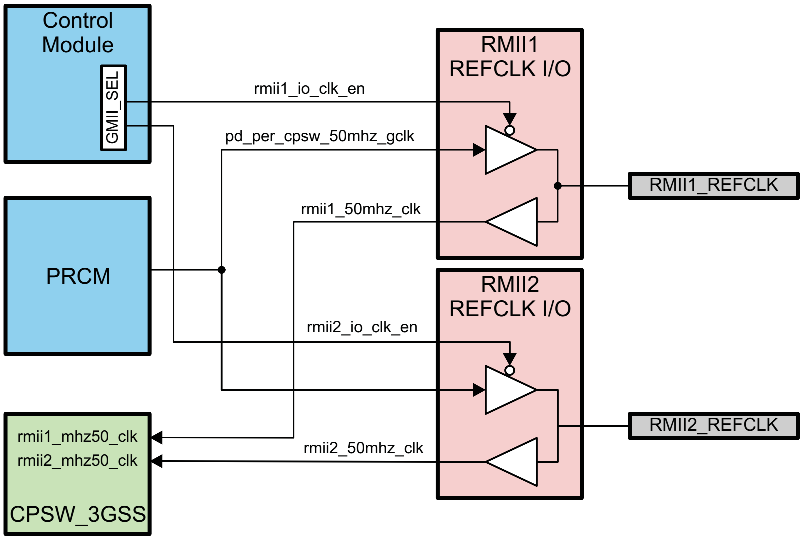
Table 15-4. Ethernet Switch Pin List

Pin	Type*	Description
GMIIx_RXCLK	I	GMII/MII Receive clock
GMIIx_RXD[3:0]	I	GMII/MII Receive data
GMIIx_RXDV	I	GMII/MII Receive data valid
GMIIx_RXER	I	GMII/MII Receive error
GMIIx_COL	I	GMII/MII Collision detect
GMIIx_CRS	I	GMII/MII Carrier sense
GMIIx_TXCLK	I	GMII/MII Transmit clock
GMII_TXD[3:0]	O	GMII/MII Transmit data
GMIIx_TXEN	O	GMII/MII Transmit enable
RGMIIx_RCLK	I	RGMII Receive clock
RGMIIx_RCTL	I	RGMII Receive control
RGMIIx_RD[3:0]	I	RGMII Receive data
RGMIIx_TCLK	O	RGMII Transmit clock
RGMIIx_TCTL	O	RGMII Transmit control
RGMIIx_TD[3:0]	O	RGMII Transmit data
RMIIx_RXD[1:0]	I	RMII Receiver data
RMIIx_RXER	I	RMII Receiver error
RMIIx_CRS_DV	I	RMII Carrier sense / Data valid
RMIIx_TXEN	O	RMII Transmit enable
RMIIx_REFCLK	I/O	RMII Reference clock
RMIIx_TXD[1:0]	O	RMII Transmit data
MDIO_CLK	O	MDIO Serial clock
MDIO_DATA	I/O	MDIO Serial data

15.2.4 Ethernet Switch RMII Clocking Details

The RMII interface reference clock pin operates as an input. When used as an input, the clock is driven by the I/O pad. The operation is controlled by the GMII_SEL[RMIIx_IO_CLK_EN] fields in the Control Module, as shown in Figure 15-2, and defaults to input mode.

Figure 15-2. Ethernet Switch RMII Clock Detail



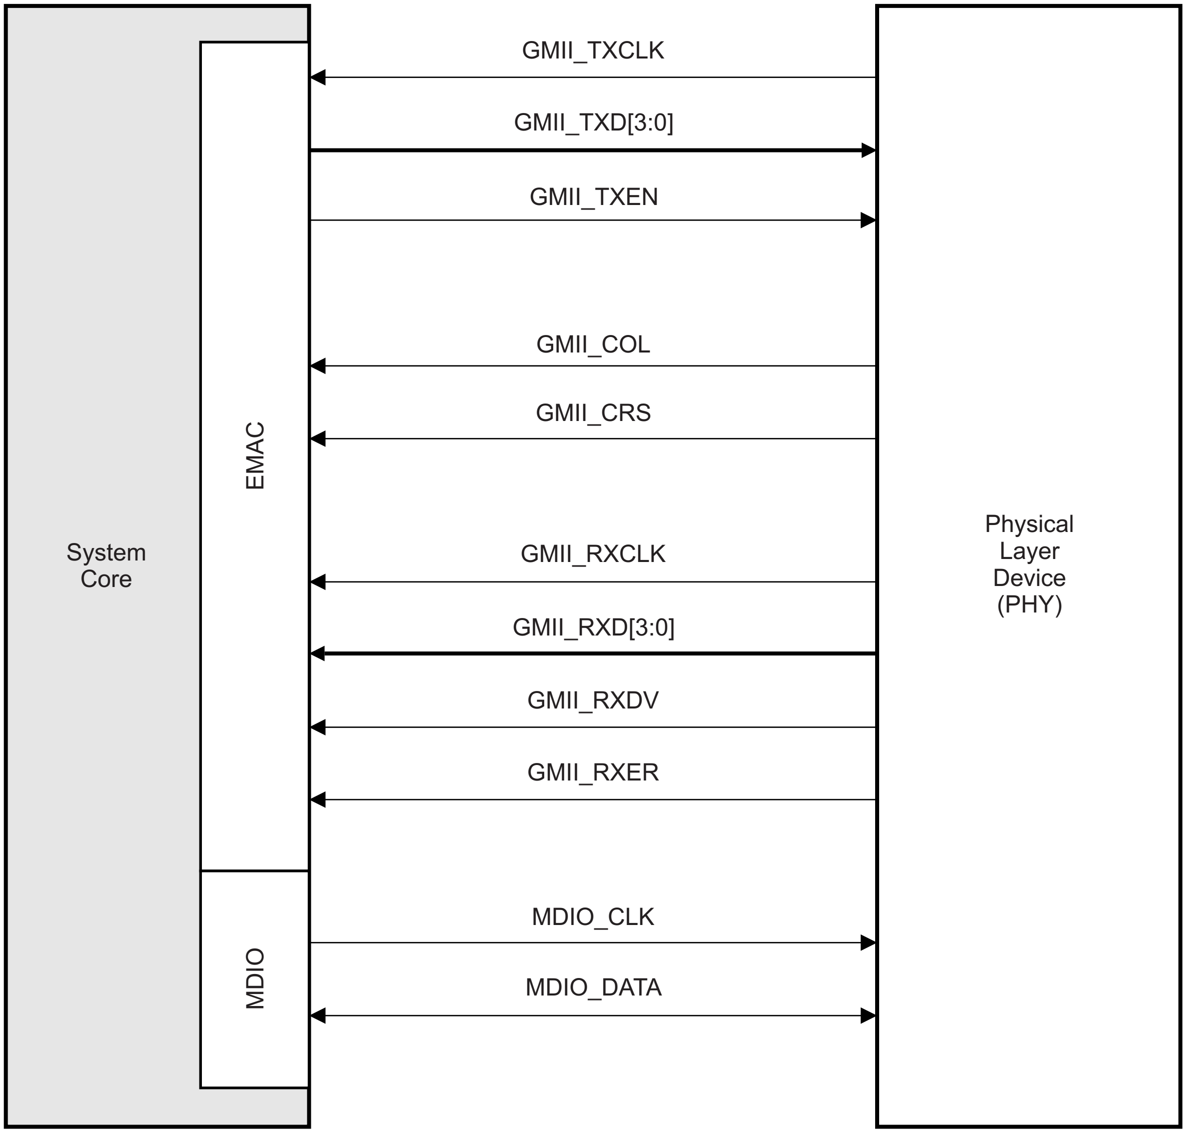
15.2.5 GMII Interface Signal Connections and Descriptions

GMII Interface can operate in MII Mode.

In MII Mode(100/10 Mbps) 3PSW operates in Full duplex and Half Duplex.

The pin connections of the GMII Interface are shown in Figure 15-3.

Figure 15-3. MII Interface Connections



The detailed description of the signals in MII Mode are explained in the following sections.

Table 15-5. GMII Interface Signal Descriptions in MII (100/10Mbps) Mode

Signal	Type	Description
GMII_TXCLK	I	The transmit clock is a continuous clock that provides the timing reference for transmit operations. The GMII_TXD and GMII_TXEN signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
GMII_TXD[3:0]	O	The transmit data pins are a collection of 4 data signals GMII_TXD[3:0] comprising 4 bits of data. GMII_TXD[0] is the least-significant bit (LSB). The signals are synchronized by GMII_TXCLK and valid only when GMII_TXEN is asserted.
GMII_TXEN	O	The transmit enable signal indicates that the GMII_TXD[3:0] pins are generating 4-bit data for use by the PHY. It is driven synchronously by GMII_TXCLK
GMII_COL	I	In half-duplex operation, the GMII_COL pin is asserted by the PHY when it detects a collision on the network. It remains asserted while the collision condition persists. This signal is not necessarily synchronous to GMII_TXCLK nor GMII_RXCLK In full-duplex operation, the GMII_COL pin is used for hardware transmit flow control. Asserting the GMII_COL pin stops packet transmissions; packets transmitting when MCOL is asserted will complete transmission. The GMII_COL pin should be held low if hardware transmit flow control is not used
GMII_CRS	I	In half-duplex operation, the GMII_CRS pin is asserted by the PHY when the network is not idle in either transmit or receive. The pin is deasserted when both transmit and receive are idle. This signal is not necessarily synchronous to GMII_TXCLK nor GMII_RXCLK. In full-duplex operation, the GMII_CRS pin should be held low.
GMII_RXCLK	I	The receive clock is a continuous clock that provides the timing reference for receive operations. The GMII_RXD, GMII_RXDV, and MRXER signals are tied to this clock. The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation.
GMII_RXD[3:0]	I	The receive data pins are a collection of 4 data signals comprising 4 bits of data. GMII_RXD[0] is the least-significant bit (LSB).The signals are synchronized by GMII_RXCLK and valid only when GMII_RXDV is asserted.
GMII_RXDV	I	The receive data valid signal indicates that the GMII_RXD pins are generating nibble data for use by the 3PSW. It is driven synchronously to GMII_RXCLK
MDIO_CLK	O	Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO_DATA pin.
MDIO_DATA	I/O	The MDIO_DATA pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_DATA pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

15.2.6 RMII Signal Connections and Descriptions

Figure 15-4 shows a device with integrated 3PSW and MDIO interfaced via a RMII connection in a typical system.

The individual CPSW and MDIO signals for the RMII interface are summarized in Table 15-6.

For more information, see either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

Figure 15-4. RMII Interface Connections

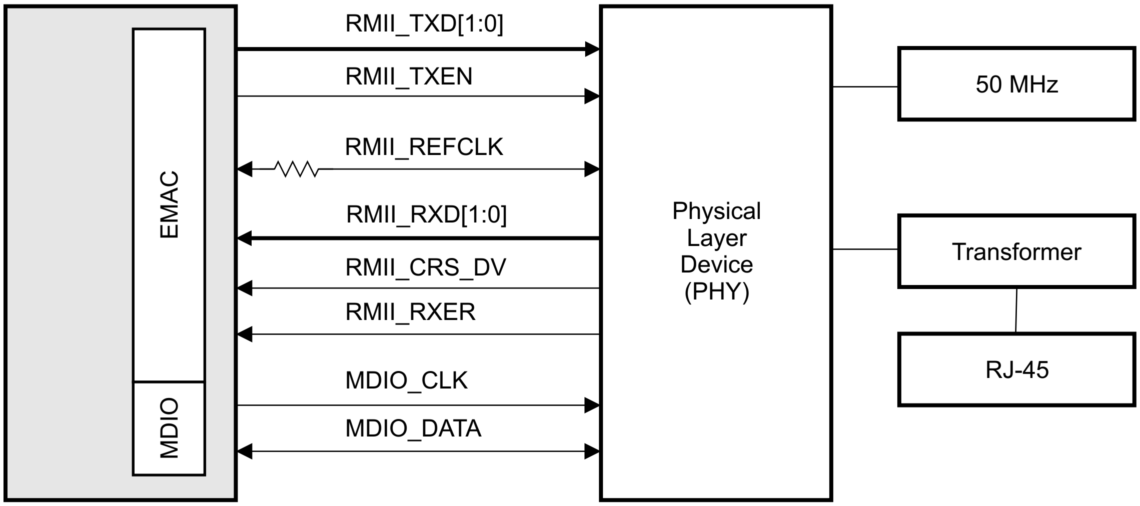


Table 15-6. RMII Interface Signal Descriptions

Signal	Type	Description
RMII_TXD[1-0]	O	Transmit data. The transmit data pins are a collection of 2 bits of data. RMII_TXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_REFCLK and valid only when RMII_TXEN is asserted.
RMII_TXEN	O	Transmit enable. The transmit enable signal indicates that the RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMII_MHZ_50_CLK.
RMII_REFCLK	I	RMII reference clock. The reference clock is used to synchronize all RMII signals. RMII_REFCLK must be continuous and fixed at 50 MHz.
RMII_RXD[1-0]	I	Receive data. The receive data pins are a collection of 2 bits of data. RMII_RXD0 is the least-significant bit (LSB). The signals are synchronized by RMII_REFCLK and valid only when RM_CRS_DV is asserted and RMII_RXER is deasserted.
RMII_CRS_DV	I	Carrier sense/receive data valid. Multiplexed signal between carrier sense and receive data valid.
RMII_RXER	I	Receive error. The receive error signal is asserted to indicate that an error was detected in the received frame.
MDIO_CLK	O	Management data clock. The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
MDIO_DATA	I/O	MDIO DATA. MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication,PHY address, register address, and data bit cycles. The MDIO_DATA signal acts as an output for all but the data bit cycles at which time it is an input for read operations.

15.2.7 RGMII Signal Connections and Descriptions

Figure 15-5 shows a device with integrated CPSW and MDIO interfaced via a RGMII connection in a typical system.

Figure 15-5. RGMII Interface Connections

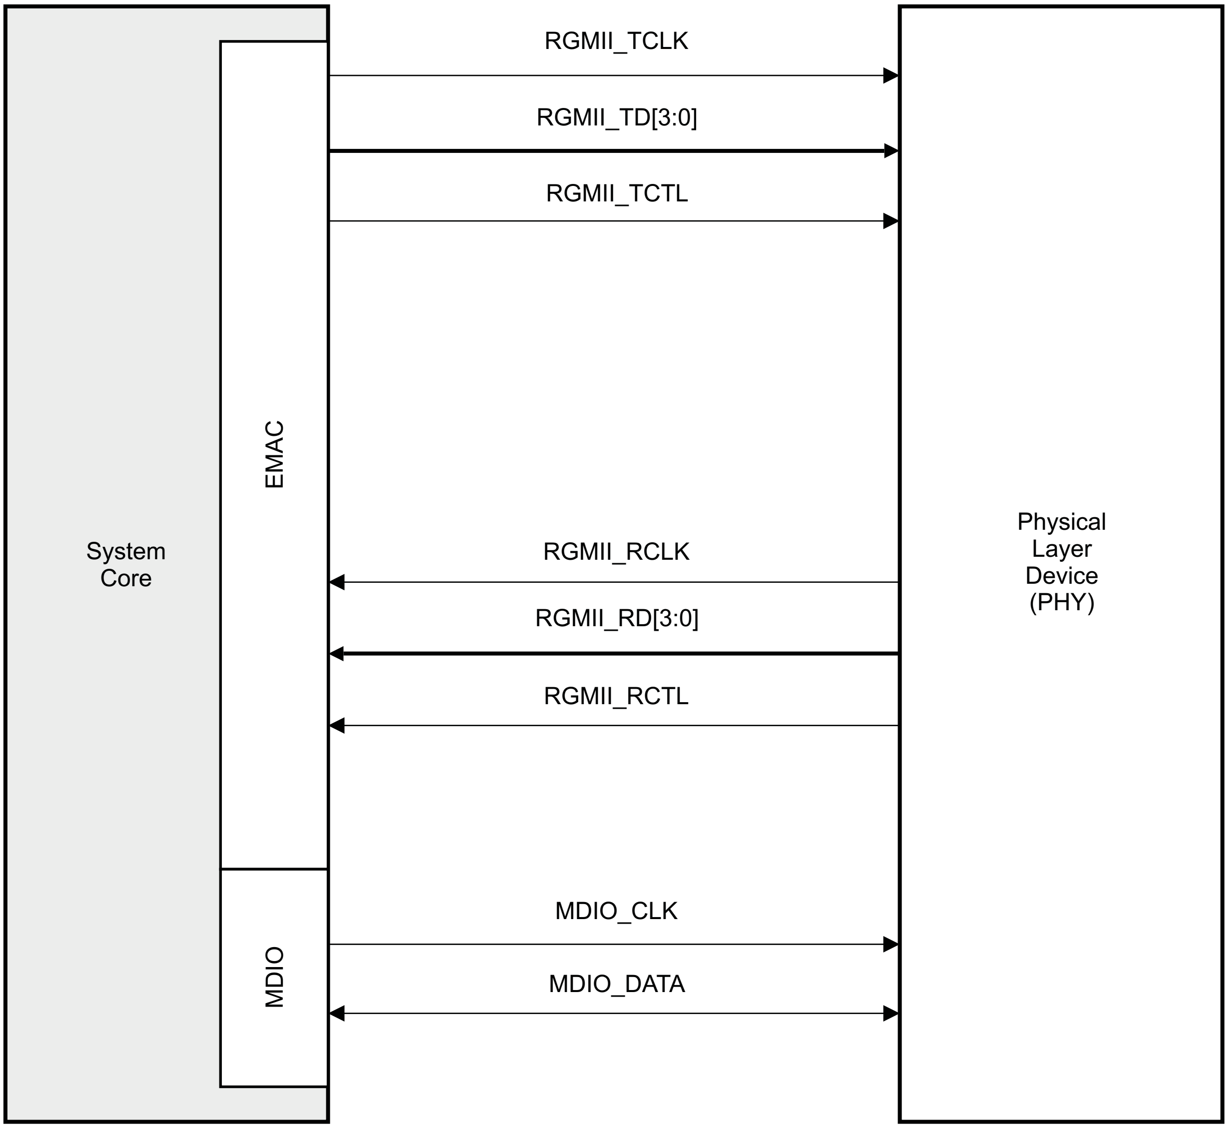

Table 15-7. RGMII Interface Signal Descriptions

Signal	Type	Description
RGMII_TD[3-0]	O	The transmit data pins are a collection of 4 bits of data. RGMII_RD0 is the least-significant bit (LSB). The signals are valid only when RGMII_TCTL is asserted.
RGMII_TCTL	O	Transmit Control/enable .The transmit enable signal indicates that the RGMII_TD pins are generating data for use by the PHY.
RGMII_TCLK	O	The transmit reference clock will be 125Mhz, 25Mhz, or 2.5Mhz depending on speed of operation.
RGMII_RD[3-0]	I	The receive data pins are a collection of 4 bits of data. RGMII_RD is the least-significant bit (LSB). The signals are valid only when RGMII_RCTL is asserted.

Table 15-7. RGMII Interface Signal Descriptions (continued)

Signal	Type	Description
RGMII_RCTL	I	The receive data valid/control signal indicates that the RGMII_RD pins are nibble data for use by the 3PSW.
RGMII_RCLK	I	The receive clock is a continuous clock that provides the timing reference for receive operations.The clock is generated by the PHY and is 2.5 MHz at 10 Mbps operation and 25 MHz at 100 Mbps operation,125 MHz at 1000Mbps of operation.
MDIO_CLK	O	Management data clock. The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin.
MDIO_DATA	I/O	MDIO DATA. MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication,PHY address, register address, and data bit cycles. The MDIO_DATA pin acts as an output for all but the data bit cycles at which time it is an input for read operations.

15.3 Functional Description

The 3 port switch (3PSW) Ethernet Subsystem peripheral are compliant to the IEEE Std 802.3 Specification. The 3PSW Ethernet Subsystem contains two RGMII/RMII interfaces, one CPPI 3.0 interface, Interrupt Controller, MDIO and CPSW_3G which contains two GMII interfaces as shown in Figure 15-6.

The subsystem modules are discussed in detail in the following sections.

15.3.1 CPSW_3G Subsystem

15.3.1.1 Interrupt Pacing

The receive and transmit pulse interrupts can be paced. The receive threshold and miscellaneous interrupts are not paced. The Interrupt pacing feature limits the number of interrupts that occur during a given period of time. For heavily loaded systems in which interrupts can occur at a very high rate (e.g. 148,800 packets per second for Ethernet), the performance benefit is significant due to minimizing the overhead associated with servicing each interrupt. Interrupt pacing increases the CPU cache hit ratio by minimizing the number of times that large interrupt service routines are moved to and from the CPU instruction cache.

Each CPU receive and transmit pulse interrupt contains an interrupt pacing sub-block (six total). Each sub-block is disabled by default allowing the selected interrupt inputs to pass through unaffected. The interrupt pacing module counts the number of interrupts that occur over a 1ms interval of time. At the end of each 1ms interval, the current number of interrupts is compared with a target number of interrupts (specified by the associated maximum number of interrupts register).

Based on the results of the comparison, the length of time during which interrupts are blocked is dynamically adjusted. The 1ms interval is derived from a 4us pulse that is created from a prescale counter whose value is set in the int_prescale value in the Int_Ctrl register. The int_prescale value should be written with the number of VBUSP_CLK periods in 4us. The pacing timer determines the interval during which interrupts are blocked and decrements every 4us. It is reloaded each time a zero count is reached. The value loaded into the pacing timer is calculated by hardware every 1ms according to the following algorithm:

```
if (intr_count > 2*intr_max)
pace_timer = 255;
else if (intr_count > 1.5*intr_max)
pace_timer = last_pace_timer*2 + 1;
else if (intr_count > 1.0*intr_max)
pace_timer = last_pace_timer + 1;
else if (intr_count > 0.5*intr_max)
pace_timer = last_pace_timer - 1;
else if (intr_count != 0)
pace_timer = last_pace_timer/2;
else
pace_timer = 0;
```

If the rate of interrupt inputs is much less than the target interrupt rate specified in the associated maximum interrupts register, then the interrupt is not blocked. If the interrupt rate is greater than the target rate, the interrupt will be “paced” at the rate specified in the interrupt maximum register. The interrupt maximum register should be written with a value between 2 and 63 inclusive indicating the target number of interrupts per milli-second.

15.3.1.2 Reset Isolation

Reset isolation for the Ethernet switch on Device is that the switch function of the ethernet IP remains active even in case of all device resets except for POR pin reset and ICEPICK COLD reset. Packet traffic to/from the 3PSW host will be flushed/dropped, but the ethernet switch will remain operational for all traffic between external devices on the switch even though the device is under-going a device reset.Pin mux configuration for ethernet related IO and reference clocks needed by the Ethernet switch IP to be active is controlled by a protected control module bit. If reset isolation is enabled, then only a POR pin or ICEPICK COLD reset event should fully reset the Ethernet switch IP including the actual switch and also the reference clocks and pin mux control specifically associated with the Ethernet IP.

15.3.1.2.1 Modes of Operation

The device has two modes of operation concerning the reset of the 3PSW Ethernet switch.

The mode is controlled by the CPSW_ISO_CTRL bit in **RESET_ISO** register of the **device control module**.This bit should default to '0'. Writes to the CPSW_ISO_CTRL bit must be supervisor mode writes.

Mode 1: CPSW_ISO_CTRL=0 (reset isolation disabled)

- This mode is selected when CPSW_ISO_CTRL bit of control module is = 0. This should be the default state of the bit after control module reset.
- Upon any device level resets, the entire CPSW_3GSS_R IP, L3/L4, control module (including all pin mux control and the CPSW_ISO_CTRL bit) is immediately reset.

Mode 2: CPSW_ISO_CTRL=1 (reset isolation enabled)

- This mode is selected when CPSW_ISO_CTRL bit of control module is = 1.
- Upon any device reset source other than POR pin or ICEPICK cold (so this includes SW global cold, any watchdog reset, warm RESETn pin, ICEPICK warm, SW global warm), the following should be true:
  - The CPSW_3GSS_R is put into ‘isolate’ mode and non-switch related portions of the IP are reset.
  - The 50-MHz and 125-MHz reference clocks to the 3PSW Ethernet Subsystem remains active throughout the entire reset condition.
  - The control for pin multiplexing for all of the signals should maintain their current configuration throughout the entire reset condition.
  - The reset isolated logic inside 3PSW Ethernet Subsystem IP which maintains the switch functionality
  -
- Upon any cold reset sources, the entire 3PSW Ethernet Subsystem, control module (including all pin mux control and the CPSW_ISO_CTRL bit itself) is reset.

15.3.1.3 Interrupts

The 3 Port Switch Ethernet Subsystem generates four interrupt events.

15.3.1.3.1 Receive Packet Completion Pulse Interrupt (RX_PULSE)

The RX_PULSE interrupt is a paced pulse interrupt selected from the 3PSW RX_PEND [7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding (RX_PEND[7:0]).

The following steps will enable the receive packet completion interrupt.

- Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the RX_INTMASK_SET register.
- The receive completion interrupt(s) to be routed to RX_PULSE is selected by setting one or more bits in the receive interrupt enable register C*n*_RX_EN. The masked interrupt status can be read in the Receive Interrupt Masked Interrupt Status (Cn_RX_STAT) register.

When the 3PSW completes a packet reception, the subsystem issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then

acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer (RX*n*_CP) in the receive DMA state RAM.

Upon reception of an interrupt, software should perform the following:

- Read the RX_STAT register to determine which channel(s) caused the interrupt.
- Process received packets for the interrupting channel(s).
- Write the 3PSW completion pointer(s) (RX*n*_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the subsystem (address of last buffer descriptor used by the subsystem). If the two values are not equal (which means that the 3PSW has received more packets than the CPU has processed), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the system has received), the pending interrupt is de-asserted. The value that the 3PSW is expecting is found by reading the receive channel*n* completion pointer register (RX*n*_CP).
- Write the value 1h to the CPDMA_EOI_VECTOR register.

To disable the interrupt:

- The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the RX_INTMASK_CLR
- The receive completion pulse interrupt could be disabled by clearing to 0 all the bits of the RX_EN.

The software could still poll for the RX_INTSTAT_RAW and RX_INTSTAT_MASKED registers if the corresponding interrupts are enabled.

15.3.1.3.2 Transmit Packet Completion Pulse Interrupt (TX_PULSE)

The TX_PULSE interrupt is a paced pulse interrupt selected from the 3PSW TX_PEND [7:0] interrupts. The transmit DMA controller has eight channels with each channel having a corresponding (TX_PEND[7:0]).

To enable the transmit packet completion interrupt:

- Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the TX_INTMASK_SET register.
- The transmit completion interrupt(s) to be routed to TX_PULSE is selected by setting one or more bits in the transmit interrupt enable register C*n*_TX_EN .The masked interrupt status can be read in the Transmit Interrupt Masked Interrupt Status (C*n*_TX_STAT) register.

When the 3PSW completes the transmission of a packet, the 3PSW subsystem issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon receiving an interrupt, software should perform the following:

- Read the TX_STAT register to determine which channel(s) caused the interrupt
- Process received packets for the interrupting channel(s).
- Write the 3PSW completion pointer(s) (TX*n*_CP). The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the 3PSW (address of last buffer descriptor used by the 3PSW). If the two values are not equal (which means that the 3PSW has transmitted more packets than the CPU has processed), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the subsystem has transferred), the pending interrupt is cleared. The value that the 3PSW is expecting is found by reading the transmit channel*n* completion pointer register (TX*n*_CP).
- Write the 2h to the CPDMA_EOI_VECTOR register.

To disable the interrupt:

- The eight channel interrupts may be individually disabled by writing to 1 the appropriate bit in the TX_INTMASK_CLR.
- The receive completion pulse interrupt could be disabled by clearing to 0 all the bits of the TX_EN. The software could still poll for the TX_INTSTAT_RAW and TX_INTSTAT_MASKED registers if the corresponding interrupts are enabled.

15.3.1.3.3 Receive Threshold Pulse Interrupt (RX_THRESH_PULSE)

The RX_THRESH_PULSE interrupt is an immediate (non-paced) pulse interrupt selected from the CPSW_3G RX_THRESH_PEND[7:0] interrupts. The receive DMA controller has eight channels with each channel having a corresponding threshold pulse interrupt (RX_THRESH_PEND [7:0]).

To enable the receive threshold pulse Interrupt:

- Enable the required channel interrupts of the DMA engine by setting 1 to the appropriate bit in the RX_INTMASK_SET register.
- The receive threshold interrupt(s) to be routed to RX_THRESH_PULSE is selected by setting one or more bits in the receive threshold interrupt enable register RX_THRESH_EN. The masked interrupt status can be read in the Receive Threshold Masked Interrupt Status (C*n*_RX_THRESH_STAT) register.

The RX_THRESH_PULSE is asserted when enabled when the channel's associated free buffer count RX_FREEBUFFER*n* is less than or equal to the corresponding RX_PENDTHRESH*n* register.

Upon receiving an interrupt, software should perform the following:

- Read the C*n*_RX_THRESH_STAT bit address location to determine which channel(s) caused the interrupt.
- Process the received packets in order to add more buffers to any channel that is below the threshold value.
- Write the CPSW_3G completion pointer(s).
- Write the value 0h to the CPDMA_EOI_VECTOR register.

The threshold pulse interrupt is an immediate interrupt intended to indicate that software should immediately process packets to preclude an overrun condition from occurring for the particular channels.

To disable the interrupt:

- The eight channel receive threshold interrupts may be individually disabled by writing to 1 the appropriate bit in the RX_INTMASK_CLR register.
- The receive threshold pulse interrupt could be disabled by clearing to Zero the corresponding bits of the RX_THRESH_EN. The software could still poll for the RX_INTSTAT_RAW and INTSTAT_MASKED registers if the corresponding interrupts are enabled.

15.3.1.3.4 Miscellaneous Pulse Interrupt (MISC_PULSE)

The MISC_PULSE interrupt is an immediate, non-paced, pulse interrupt selected from the miscellaneous interrupts (EVNT_PEND, STAT_PEND, HOST_PEND, MDIO_LINKINT, MDIO_USERINT). The miscellaneous interrupt(s) is selected by setting one or more bits in the C*n*_MISC_EN[4:0] register. The masked interrupt status can be read in the C*n*_MISC_STAT[4:0] register. Upon reception of an interrupt, software should perform the following:

- Read the Misc_Stat[4:0] register to determine which caused the interrupt.
- Process the interrupt.
- Write the appropriate value (0x3) to the CPDMA_EOI_VECTOR register.
- Write a 1 to the appropriate bit in the MDIOLINKINTRAW register.

This device does not support multiple link interrupts. Only MDIO_LINKINT[0] and MDIO_USERINT[0] are used. MDIO_LINKINT[1] and MDIO_USERINT[1] are not used.

15.3.1.3.4.1 EVNT_PEND (CPTS_PEND) Interrupt

See Section 15.3.7, *Common Platform Time Sync (CPTS)*, for information on the time sync event interrupt.

15.3.1.3.4.2 Statistics Interrupt

The statistics level interrupt (STAT_PEND) will be asserted if enabled when any statistics value is greater than or equal to 0x80000000. The statistics interrupt is cleared by writing to decrement all statistics values greater than 0x80000000 (such that their new values are less than 0x80000000). The statistics interrupt is enabled by setting to one the appropriate bit in the INTMASK_SET register in the CPDMA submodule.

The statistics interrupt is disabled by writing one to the appropriate bit in the INTMASK_CLR register. The raw and masked statistics interrupt status may be read by reading the TX_IntStat_Raw and TX_IntStat_Masked registers, respectively

15.3.1.3.4.3 Host Error Interrupt

The host error interrupt (HOST_PEND) will be asserted if enabled when a host error is detected during transmit or receive CPDMA transactions. The host error interrupt is intended for software debug, and is cleared by a warm reset or a system reset. The raw and masked statistics interrupt status can be read by reading the TX_INTSTAT_RAW and TXINTSTAT_MASKED registers, respectively.

The following list shows the transmit host error conditions:

- SOP error
- OWNERSHIP bit not set in SOP buffer
- next buffer descriptor pointer without EOP set to 0
- buffer pointer set to 0
- buffer length set to 0
- packet length error

The receive host error conditions are show in the following list:

- Ownership bit not set in input buffer.
- Zero buffer pointer.
- Zero buffer Length on non-SOP descriptor.
- SOP buffer length not greater than offset.

The host error interrupt is disabled by clearing to 0 the appropriate bit in the CPDMA_INTMASK_CLR register.

15.3.1.3.4.4 MDIO Interrupts

MDIO_LINKINT is set if there is a change in the link state of the PHY corresponding to the address in the PHYADDRMON field of the MDIOUSERPHYSEL*n* register and the corresponding LINKINTENB bit is set.The MDIO_LINKINT event is also captured in the MDIOLINKINTMASKED register.When the GO bit in the MDIOUSERACCESS*n* registers transitions from 1 to 0, indicating the completion of a user access, and the corresponding USERINTMASKSET bit in the MDIOUSERINTMASKSET register is set, the MDIO_USERINT signal is asserted 1. The MDIO_USERINT event is also captured in the MDIOUSERINTMASKED register.

To enable the miscellaneous pulse interrupt:

The miscellaneous interrupt(s) is selected by setting one or more bits in the miscellaneous interrupt enable register (MISC_EN).

- The Statistics interrupt is enabled by setting to 1 the STAT_INT_MASK bit in the DMA_INTMASK_SET register.
- The HOST_PEND is enabled by setting to 1 the HOST_ERR_INT_MASK in the DMA_INTMASK_SET register.

Upon receiving of an interrupt, software should perform the following:

- Read the C*n*_MISC_STAT register to determine the source of the interrupt.
- Process the interrupt.
- Write the value 3h to the CPDMA_EOI_VECTOR register.

15.3.1.4 Embedded Memories

Memory Type Description	Number of Instances
Single port 2560 by 64 RAM	3 (Packet FIFOs)
Single port 64-word by 1152-bit RAM	1 (ALE)
Single port 2048-word by 32-bit RAM	1 (CPPI)

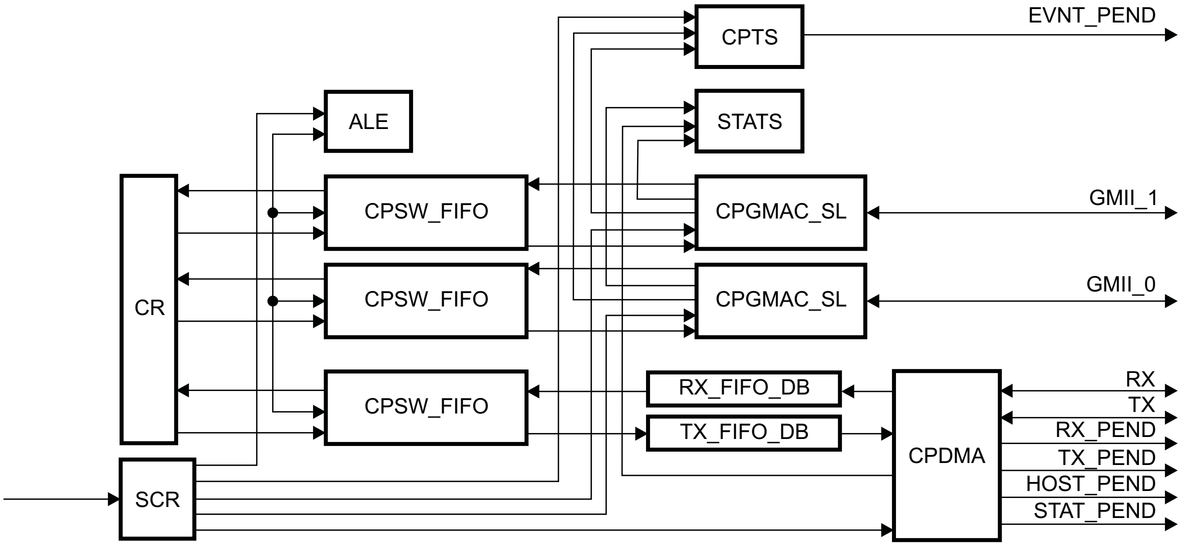
15.3.2 CPSW_3G

The CPSW_3G GMII interfaces are compliant to the IEEE Std 802.3 Specification.

The CPSW_3G contains two CPGMAC_SL interfaces (ports 1 and 2), one CPPI 3.0 interface Host Port (port 0), Common Platform Time Sync (CPTS), ALE Engine and CPDMA.

The top level block diagram of CPSW_3G is shown below:

Figure 15-6. CPSW_3G Block Diagram



15.3.2.1 Media Independent Interface (GMII)

The CPSW_3G contains two CPGMAC_SL submodules. Each CPGMAC_SL has a single GMII interface. The CPGMAC_SL submodules are ports 1 and 2. For more details, see Section 15.3.3, *Ethernet Mac Sliver (CPGMAC_SL)*.

15.3.2.2 IEEE 1588v2 Clock Synchronization Support

The CPSW_3G supports IEEE 1588v2 clock synchronization. Ethernet GMII Transmit (egress) and receive (ingress) time sync operation are also supported.

15.3.2.2.1 IEEE 1588v2 Receive Packet Operation

There are two CPSW_3G receive time sync interfaces for each ethernet port. The first is the TS_RX_MII interface and the second is the TS_RX_DEC interface. Both interfaces are generated in the switch and are input to the CPTS module. There are register bits in the CPSW_3G that control time sync operations in addition to the registers in the CPTS module. The pX_ts_rx_en bit in the switch Px_Ctrl register must be set for receive time sync operation to be enabled (TS_RX_MII).

The TS_RX_MII interface issues a record signal (pX_ts_rx_mii_rec) along with a handle (pX_ts_rx_mii_hndl[3:0]) to the CPTS controller for each packet that is received. The record signal is a single clock pulse indicating that a receive packet has been detected at the associated port MII interface.

The handle value is incremented with each packet and rolls over to zero after 15. There are 16 possible handle values so there can be a maximum of 16 packets “in flight” from the TS_RX_MII to the TS_RX_DEC block (through the CPGMAC_SL) at any given time. A handle value is reused (not incremented) for any received packet that is shorter than about 31 octets (including preamble). Handle reuse on short packets prevents any possible overrun condition if multiple fragments are consecutively received.

The TS_RX_MII logic is in the receive wireside clock domain. There is no decode logic in the TS_RX_MII to determine if the packet is a time sync event packet or not. Each received packet generates a record signal and new handle. The handle is sent to the CPTS controller with the record pulse and the handle is also sent to the TS_RX_DEC block along with the packet. The packet decode is performed in the TS_RX_DEC block. The decode function is separated from the record function because in some systems the incoming packet can be encrypted. The decode function would be after packet decryption in those systems.

The TS_RX_DEC function decodes each received packet and determines if the packet meets the time sync event packet criteria. If the packet is determined to be a time sync event packet, then the time sync event packet is signaled to the CPTS controller via the TS_RX_DEC interface (pX_ts_rx_dec_evnt, pX_ts_rx_dec_hndl[3:0], pX_ts_rx_dec_msg_type, pX_ts_rx_dec_seq_id). The event signal is a single clock pulse indicating that the packet matched the time sync event packet criteria and that the associated packet handle, message type, and sequence ID are valid. No indication is given for received packets that do not meet the time sync event criteria. The 16-bit sequence ID is found in the time sync event packet at the sequence ID offset into the PTP message header (pX_ts_seq_id_offset). A packet is determined to be a receive event packet under the following conditions:

15.3.2.2.1.1 Annex F

1. Receive time sync is enabled (pX_ts_rx_en is set in the switch Px_Ctrl register).
2. One of the following sequences is true:

   Where the first packet ltype matches:

   - ts_ltype1 and pX_ts_ltype1_en is set
   - ts_ltype2 and pX_ts_ltype2_en is set
   - vlan_ltype1 and pX_vlan_ltype1_en is set and the second packet ltype matches ts_ltype1 and pX_ts_ltype1_en is set
   - vlan_ltype1 and pX_vlan_ltype1_en is set and the second packet ltype matches ts_ltype2 and pX_ts_ltype2_en is set
   - vlan_ltype2 and pX_vlan_ltype2_en is set and the second packet ltype matches ts_ltype1 and pX_ts_ltype1_en is set
   - vlan_ltype2 and pX_vlan_ltype2_en is set and the second packet ltype matches ts_ltype2 and pX_ts_ltype2_en is set
   - vlan_ltype1 and pX_vlan_ltype1_en is set and the second packet ltype matches vlan_ltype2 and pX_vlan_ltype2_en is set and the third packet ltype matches ts_ltype1 and pX_ts_ltype1_en is set
   - vlan_ltype1 and pX_vlan_ltype1_en is set and the second packet ltype matches vlan_ltype2 and pX_vlan_ltype2_en is set and the third packet ltype matches ts_ltype2 and pX_ts_ltype2_en is set
3. The PTP message begins in the byte after the LTYPE.
4. The packet message type is enabled in the pX_ts_msg_type_en field in the Px_TS_SEQ_MTYPE register.
5. The packet was received without error (not long/short/mac_ctl/crc/code/align).
6. The ALE determined that the packet is to be sent only to the host (port 0).

15.3.2.2.1.2 Annex D

1. Receive time sync is enabled (pX_ts_rx_en is set in the switch Px_Ctrl register).
2. One of the following sequences is true:

   Where the first packet ltype matches:

   - 0x0800 and pX_ts_annex_d_en is set
   - vlan_ltype1 and pX_vlan_ltype1_en is set and the second packet ltype matches 0x0800 and pX_ts_annex_d_en is set
   - vlan_ltype2 and pX_vlan_ltype2_en is set and the second packet ltype matches 0x0800 and pX_ts_annex_d_en is set
   - vlan_ltype1 and pX_vlan_ltype1_en is set and the second packet ltype matches vlan_ltype2 and pX_vlan_ltype2_en is set and the third packet ltype matches 0x0800 and pX_ts_annex_d_en is set
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IP_VERSION).

   Note: The byte numbering assumes that there are no vlans. The byte number is intended to show the relative order of the bytes.
4. Byte 22 contains 0x00 if the pX_ts_ttl_nonzero bit in the switch Px_Ctrl register is zero or byte 22 contains any value if pX_ts_ttl_nonzero is set. Byte 22 is the time to live field.

5. Byte 23 contains 0x11 (UDP Fixed).
6. Byte 30 contains decimal 224 (0xe0).
7. Byte 31 contains 0x00.
8. Byte 32 contains 0x01.
9. Byte 33 contains one of the following:
   - Decimal 129 and the pX_ts_129 bit in the switch Px_Ctrl register is set
   - Decimal 130 and the pX_ts_130 bit in the switch Px_Ctrl register is set
   - Decimal 131 and the pX_ts_131 bit in the switch Px_Ctrl register is set
   - Decimal 129 and the pX_ts_132 bit in the switch Px_Ctrl register is set
10. Bytes 36 and 37 contain one of the following:
    - Decimal 0x01 and 0x3f respectively and and the pX_ts_319 bit in the switch Px_Ctrl register is set.
    - Decimal 0x01 and 0x40 respectively and and the pX_ts_320 bit in the switch Px_Ctrl register is set.
11. The PTP message begins in byte 42.
12. The packet message type is enabled in the pX_ts_msg_type_en field in Px_Ctrl.
13. The packet was received without error (not long/short/mac_ctl/crc/code/align).
14. The ALE determined that the packet is to be sent only to the host (port 0).

15.3.2.2.2 IEEE 1588v2 Transmit Packet Operation

There are two CPSW_3G transmit time sync interfaces for each ethernet port. The first is the TS_TX_DEC interface and the second is the TS_TX_MII interface. Both interfaces are generated in the switch and are input to the CPTS module. The pX_ts_tx_en bit in the Px_Ctrl register must be set for transmit time sync operation to be enabled.

The TS_TX_DEC function decodes each packet to be transmitted and determines if the packet meets the time sync event packet criteria. If the packet is determined to be a time sync event packet, then the time sync event is signaled to the CPTS controller via the TS_TX_DEC interface (pX_ts_tx_dec_evnt, pX_ts_tx_dec_hndl[3:0], pX_ts_tx_dec_msg_type, pX_ts_tx_dec_seq_id). The event signal is a single clock pulse indicating that the packet matched the time sync event packet criteria and that the associated packet handle, message type, and sequence ID are valid.

The 16-bit sequence ID is found in the time sync event packet at the sequence ID offset into the message header (pX_ts_seq_id_offset). No indication is given for transmit packets that do not meet the time sync event criteria. The time sync event packet handle is also passed along with the packet to the TS_TX_MII with an indication that the packet is a time sync event packet. Unlike receive, only transmit event packets increment the handle value. The decode function is separated from the record function because some systems may encript the packet. The encription is after the decode function on transmit (egress). A packet is determined to be a transmit event packet if the following is met:

15.3.2.2.2.1 Annex F

1. Transmit time sync is enabled (pX_ts_tx_en is set in the switch Px_Ctrl register).
2. One of the following sequences is true:
   - The first packet ltype matches ts_ltype1 and pX_ts_ltype1_en is set
   - The first packet ltype matches ts_ltype2 and pX_ts_ltype2_en is set
   - The first packet ltype matches vlan_ltype1 and pX_vlan_ltype1_en is set and the second packet matches ts_ltype1 and pX_ts_ltype1_en is set
   - The first packet ltype matches vlan_ltype1 and pX_vlan_ltype1_en is set and the second packet ltype matches ts_ltype2 and pX_ts_ltype2_en is set
   - The first packet ltype matches vlan_ltype2 and pX_vlan_ltype2_en is set and the second packet ltype matches ts_ltype1 and pX_ts_ltype1_en is set
   - The first packet ltype matches vlan_ltype2 and pX_vlan_ltype2_en is set and the second packet ltype matches ts_ltype2 and pX_ts_ltype2_en is set

  - The first packet ltype matches vlan_ltype1 and pX_vlan_ltype1_en is set and the second packet ltype matches vlan_ltype2 and pX_vlan_ltype2_en is set and the third packet ltype matches ts_ltype1 and pX_ts_ltype1_en is set
  - The first packet ltype matches vlan_ltype1 and pX_vlan_ltype1_en is set and the second packet ltype matches vlan_ltype2 and pX_vlan_ltype2_en is set and the third packet ltype matches ts_ltype2 and pX_ts_ltype2_en is set

3. The packet message type is enabled in pX_ts_msg_type_en.
4. The packet was received by the host (port 0).

15.3.2.2.2.2 Annex D

1. Transmit time sync is enabled (pX_ts_tx_en is set in the switch Px_Ctrl register).
2. One of the following sequences is true:
   - The first packet ltype matches 0x0800 and pX_ts_annex_d_en is set
   - The first packet ltype matches vlan_ltype1 and pX_vlan_ltype1_en is set and the second packet ltype matches 0x0800 and pX_ts_annex_d_en is set
   - The first packet ltype matches vlan_ltype2 and pX_vlan_ltype2_en is set and the second packet ltype matches 0x0800 and pX_ts_annex_d_en is set
   - The first packet ltype matches vlan_ltype1 and pX_vlan_ltype1_en is set and the second packet ltype matches vlan_ltype2 and pX_vlan_ltype2_en is set and the third packet ltype matches 0x0800 and pX_ts_annex_d_en is set
3. Byte 14 (the byte after the LTYPE) contains 0x45 (IP_VERSION).

   Note: The byte numbering assumes that there are no vlans. The byte number is intended to show the relative order of the bytes. If VLAN(s) are present, then the byte numbers push down.
4. Byte 22 contains 0x00 if the pX_ts_ttl_nonzero bit in the switch Px_Ctrl register is zero or byte 22 contains any value if pX_ts_ttl_nonzero is set. Byte 22 is the time to live field.
5. Byte 23 contains 0x11 (UDP Fixed).
6. Byte 30 contains decimal 224 (0xe0)
7. Byte 31 contains 0x00
8. Byte 32 contains 0x01
9. Byte 33 contains one of the following:
   - Decimal 129 and the pX_ts_129 bit in the switch Px_Ctrl register is set
   - Decimal 130 and the pX_ts_130 bit in the switch Px_Ctrl register is set
   - Decimal 131 and the pX_ts_131 bit in the switch Px_Ctrl register is set
   - Decimal 132 and the pX_ts_132 bit in the switch Px_Ctrl register is set
10. Bytes 36 and 37 contain either of the following:
    - Decimal 1 (hex 0x01) and decimal 63 (hex 0x3f) respectively and and the pX_ts_319 bit in the switch Px_Ctrl register is set
    - Decimal 1 (hex 0x01) and decimal 64 (hex 0x40) respectively and and the pX_ts_320 bit in the switch Px_Ctrl register is set
11. The PTP message begins in byte 42 (this is offset 0).
12. The packet message type is enabled in pX_ts_msg_type_en.
13. The packet was received by the host (port 0).

The TS_TX_MII interface issues a single clock record signal (pX_ts_tx_mii_rec) at the beginning of each transmitted packet. If the packet is a time sync event packet then a single clock event signal (pX_ts_tx_mii_evnt) along with a handle (pX_ts_rx_mii_hndl[2:0]) will be issued before the next record signal for the next packet. The event signal will not be issued for packets that did not meet the time sync event criteria in the TS_TX_DEC function. If consecutive record indications occur without an interleaving event indication, then the packet associated with the first record was not a time sync event packet.

The record signal is a single clock pulse indicating that a transmit packet egress has been detected at the associated port MII interface. The handle value is incremented with each time sync event packet and rolls over to zero after 7. There are 8 possible handle values so there can be a maximum of eight time sync event packets “in flight” from the TS_TX_DEC to the TS_TX_MII block at any given time. The handle value increments only on time sync event packets. The TS_TX_MII logic is in the transmit wireside clock domain.

15.3.2.3 Device Level Ring (DLR) Support

Device Level Ring (DLR) support is enabled by setting the dlr_en bit in the CPSW_Ctrl register. When enabled, incoming received DLR packets are detected and sent to queue 3 (highest priority) of the egress port(s). If the host port is the egress port for a DLR packet then the packet is sent on the CPDMA Rx channel selected by the p0_dlr_cpdma_ch field in the P0_Ctrl register. The supervisor node MAC address feature is supported with the dlr_unicast bit in the unicast address table entry.

When set, the dlr_unicast bit causes a packet with the matching destination address to be flooded to the vlan_member_list minus the receive port and minus the host port (the port_number field in the unicast address table entry is a don’t care). Matching dlr_unicast packets are flooded regardless of whether the packet is a DLR packet or not. The en_p0_uni_flood bit in the ALE_Ctrl register has no effect on DLR unicast packets. Packets are determined to be DLR packets, as shown:

1. DLR is enabled (dlr_en is set in the switch CPSW_Ctrl register).
2. One of the following sequences is true:
   - The first packet ltype matches vlan_ltype1 and pX_vlan_ltype1_en is set and the second packet ltype matches dlr_ltype.
   - The first packet ltype matches vlan_ltype2 and pX_vlan_ltype2_en is set and the second packet ltype matches dlr_ltype.
   - The first packet ltype matches vlan_ltype1 and pX_vlan_ltype1_en is set and the second packet ltype matches vlan_ltype2 and pX_vlan_ltype2_en is set and the third packet ltype matches dlr_ltype.

15.3.2.4 CPDMA RX and TX Interfaces

The CPDMA submodule is a CPPI 3.0 compliant packet DMA transfer controller. The CPPI 3.0 interface is port 0.

After reset, initialization, and configuration the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the STATERAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory in accordance with CPPI 3.0 protocol. The DMA controller writes the packet into the external transmit FIFO in 64-byte bursts (maximum).

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The receive DMA controller writes the receive packet data to external memory in accordance with CPPI 3.0 protocol. See the CPPI Buffer Descriptors section for detailed description of Buffer Descriptors

15.3.2.4.1 CPPI Buffer Descriptors

The buffer descriptor is a central part of the 3PSW Ethernet Subsytem and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data.

Host Software sends and receives network frames via the CPPI 3.0 compliant host interface. The host interface includes module registers and host memory data structures. The host memory data structures are buffer descriptors and data buffers. Buffer descriptors are data structures that contain information about a single data buffer. Buffer descriptors may be linked together to describe frames or queues of frames for transmission of data and free buffer queues available for received data.

Note: The 8k bytes of Ethernet Subsystem CPPI RAM begin at address 0x4a102000 and end at 0x4a103FFF from the 3PSW perspective. The buffer descriptors programmed to access the CPPI RAM memory should use the address range from 0x4a102000.

15.3.2.4.1.1 TX Buffer Descriptors

A TX buffer descriptor is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Figure 15-7. Tx Buffer Descriptor Format

15.3.2.4.1.1.1 CPPI Tx Data Word – 0

Next Descriptor Pointer

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL.

If the pNext pointer is initially NULL, and more packets need to be queued for transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

15.3.2.4.1.1.2 CPPI Tx Data Word – 1

Buffer Pointer

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the **buffer_pointer**. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

15.3.2.4.1.1.3 CPPI Tx Data Word – 2

Buffer _Offset

Buffer Offset – Indicates how many unused bytes are at the start of the buffer. A value of 0x0000 indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The host sets the buffer_offset value (which may be zero to the buffer length minus 1). Valid only on sop.

Buffer _Length

Buffer Length – Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host sets the buffer_length. The buffer_length must be greater than zero.

15.3.2.4.1.1.4 CPPI Tx Data Word – 3

Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet.In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise,the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not start of packet buffer

1 - Start of packet buffer

End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

0 - Not end of packet buffer.

1 - End of packet buffer.

Ownership

When set this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

0 - The packet is owned by the host

1 - The packet is owned by the port

EOQ

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

0 - The Tx queue has more packets to transfer.

1 - The Descriptor buffer is the last buffer in the last packet in the queue.

teardown_Complete

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be

transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission. Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

0 - The port has not completed the teardown process.

1 - The port has completed the commanded teardown process.

pass_crc

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC.When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

0 – The CRC is not included with the packet data and packet length.

1 – The CRC is included with the packet data and packet length.

to_port

To Port – Port number to send the directed packet to. This field is set by the host. This field is valid on SOP. Directed packets go to the directed port, but an ALE lookup is performed to determine untagged egress in VLAN_AWARE mode.

1 – Send the packet to port 1 if to_port_en is asserted.

2 – Send the packet to port 2 if to_port_en is asserted.

To_port_enable

To Port Enable – Indicates when set that the packet is a directed packet to be sent to the to_port field port number. This field is set by the host. The packet is sent to one port only (index not mask). This bit is valid on SOP.

0 – not a directed packet

1 – directed packet

Packet Length

Specifies the number of bytes in the entire packet. Offset bytes are not included. The sum of the buffer_length fields should equal the packet_length. Valid only on SOP. The packet length must be greater than zero. The packet data will be truncated to the packet length if the packet length is shorter than the sum of the packet buffer descriptor buffer lengths. A host error occurs if the packet length is greater than the sum of the packet buffer descriptor buffer lengths

15.3.2.4.1.2 RX Buffer Descriptors

An RX buffer descriptor is a contiguous block of four 32-bit data words aligned on a 32-bit word boundary.

Figure 15-8. Rx Buffer Descriptor Format

Word 0

31 – 0
Next Descriptor Pointer

Word 1

15 – 11	10 – 0
Reserved	packet_length

15.3.2.4.1.2.1 CPPI Rx Data Word – 0

next_descriptor_pointer

The 32-bit word aligned memory address of the next buffer descriptor in the RX queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the **next_descriptor_pointer**.

15.3.2.4.1.2.2 CPPI Rx Data Word – 1

buffer_pointer

The byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the **buffer_pointer**.

15.3.2.4.1.2.3 CPPI Rx Data Word – 2

Buffer _Offset

Buffer Offset – Indicates how many unused bytes are at the start of the buffer. A value of 0x0000 indicates that there are no unused bytes at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The port writes the **buffer_offset** with the value from the **rx_buffer_offset** register value. The host initializes the **buffer_offset** to zero for free buffers. The **buffer_length** must be greater than the **rx_buffer_offset** value. The buffer offset is valid only on **sop**.

Buffer _Length

Buffer Length – Indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host initializes the **buffer_length**, but the port may overwrite the host initiated value with the actual buffer length value on SOP and/or EOP buffer descriptors. SOP buffer length values will be overwritten if the packet size is less than the size of the buffer or if the offset is nonzero. EOP buffer length values will be overwritten if the entire buffer is not filled up with data. The **buffer_length** must be greater than zero.

15.3.2.4.1.2.4 CPPI Rx Data Word – 3

Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet.In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

Ownership (OWNER) Flag

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL).The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

Pass CRC (PASSCRC) Flag

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC.This flag should be cleared by the software application before submitting the descriptor to the receive queue.

Long (Jabber) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RX_CEF_EN bit was set in the MACCTRL. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

Short (Fragment) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RX_CSF_EN bit was set in the MACCTRL.

Control Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RX_CMF_EN bit was set in the MACCTRL.

Overrun Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

Pkt_error Flag

Packet Contained Error on Ingress –

00 – no error

01 – CRC error on ingress

10 – Code error on ingress

11 – Align error on ingress

rx_vlan_encap

VLAN Encapsulated Packet – Indicates when set that the packet data contains a 32-bit VLAN header word that is included in the packet byte count. This field is set by the port to be the value of the CPSW control register rx_vlan_encap bit

from_port

From Port – Indicates the port number that the packet was received on (ingress to the switch).

Packet Length

Specifies the number of bytes in the entire packet. The packet length is reduced to 12-bits. Offset bytes are not included. The sum of the buffer_length fields should equal the packet_length. Valid only on SOP.

15.3.2.4.2 Receive DMA Interface

The Receive DMA is an eight channel CPPI 3.0 compliant interface. Each channel has a single queue for frame reception.

15.3.2.4.2.1 Receive DMA Host Configuration

To configure the Rx DMA for operation the host must perform the following:

- Initialize the receive addresses.
- Initialize the Rx_HDP Registers to zero.
- Enable the desired receive interrupts in the IntMask register.
- Write the rx_buffer_offset register value.
- Setup the receive channel(s) buffer descriptors in host memory as required by CPPI 3.0.
- Enable the RX DMA controller by setting the rx_en bit in the Rx_Ctrl register.

15.3.2.4.2.2 Receive Channel Teardown

The host commands a receive channel teardown by writing the channel number to the Rx_Teardown register. When a teardown command is issued to an enabled receive channel the following will occur:

- Any current frame in reception will complete normally.
- The teardown_complete bit will be set in the next buffer descriptor in the chain

if there is one.

- The channel head descriptor pointer will be cleared to zero
- A receive interrupt for the channel will be issued to the host.
- The host should acknowledge a teardown interrupt with a 0xfffffffc acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a 0xfffffffc acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be 0xfffffffc if the interrupt was due to a teardown command.

15.3.2.4.3 Transmit DMA Interface

The Transmit DMA is an eight channel CPPI 3.0 compliant interface. Priority between the eight queues may be either fixed or round robin as selected by tx_ptype in the DMA_Ctrl register. If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round robin priority proceeds from channel 0 to channel 7. Packet Data transfers occur on the TX_VBUSP interface in 64-byte maximum burst transfers

15.3.2.4.3.1 Transmit DMA Host Configuration

To configure the TX DMA for operation the host must do the following:

- Initialize the Tx_HDP registers to a zero value.
- Enable the desired transmit interrupts in the IntMask register.
- Setup the transmit channel(s) buffer descriptors in host memory as defined in CPPI 3.0.
- Configure and enable the transmit operation as desired in the Tx_Ctrl register.
- Write the appropriate Tx_HDP registers with the appropriate values to start transmit operations.

15.3.2.4.3.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the Tx_Teardown register. When a teardown command is issued to an enabled transmit channel the following will occur:

- Any frame currently in transmission will complete normally
- The teardown complete bit will be set in the next sop buffer descriptor (if there is one).
- The channel head descriptor pointer will be set to zero.
- An interrupt will be issued to inform the host of the channel teardown.
- The host should acknowledge a teardown interrupt with a 0xfffffffc acknowledge value

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete buffer descriptor bit. The port does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with a 0xfffffffc acknowledge value (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location to determine if the interrupt was due to a commanded teardown. The read value will be 0xfffffffc if the interrupt was due to a teardown command.

15.3.2.4.4 Transmit Rate Limiting

Transmit operations can be configured to rate limit the transmit data for each transmit priority. Rate limiting is enabled for a channel when the tx_rlim[7:0] bit associated with that channel is set in the DMA_Ctrl register. Rate limited channels must be the highest priority channels. For example, if two rate limited channels are required then tx_rlim[7:0] should be set to 11000000 with the msb corresponding to channel 7.

When any channels are configured to be rate-limiting, the priority type must be fixed for transmit. Round-robin priority type is not allowed when rate-limiting. Each of the eight transmit priorities has an associated register to control the rate at which the priority is allowed to send data (Tx_Pri(7..0)_Rate) when the channel is rate-limiting. Each priority has a send count (pri(7..0)_send_cnt[13:0]) and an idle count (pri(7..0)_idle_cnt[13:0]). The transfer rate includes the inter-packet gap (12 bytes) and the preamble (8 bytes). The rate in Mbits/second that each priority is allowed to send is controlled by the below equation.

Priority Transfer rate in Mbit/s = ((priN_idle_cnt/(priN_idle_cnt + priN_send_cnt)) * frequency * 32

Where the frequency is the CLK frequency.

15.3.2.4.5 Command IDLE

The cmd_idle bit in the DMA_Ctrl register allows CPDMA operation to be suspended. When the idle state is commanded, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell fifo will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Commanded idle is similar in operation to emulation control and clock stop.

15.3.2.5 VLAN Aware Mode

The CPSW_3G is in VLAN aware mode when the CPSW Control register vlan_aware bit is set. In VLAN aware mode ports 0 receive packets (out of the CPSW_3G) may or may not be VLAN encapsulated depending on the CPSW Control register rx_vlan_encap bit. The header packet VLAN is generated as described in Section 15.3.3, *Ethernet Mac Sliver (CPGMAC_SL)*. Port 0 receive packet data is never modified. VLAN is not removed regardless of the force untagged egress bit for Port 0. VLAN encapsulated receive packets have a 32-bit VLAN header encapsulation word added to the packet data.VLAN encapsulated packets are specified by a set rx_vlan_encap bit in the packet buffer descriptor.

Port 0 transmit packets are never VLAN encapsulated (encapsulation is not allowed).

In VLAN aware mode, transmitted packet data is changed depending on the packet type (pkt_type), packet priority (pkt_pri), and VLAN information as shown in the below tables:

Figure 15-9. VLAN Header Encapsulation Word

31-29	28	27-16
HDR_PKT_Priority	HDR_PKT_CFI	HDR_PKT_Vid

15-10	9-8	7-0
Reserved	PKT_Type	Reserved

Table 15-8. VLAN Header Encapsulation Word Field Descriptions

Field	Description
HDR_PKT_Priority	Header Packet VLAN priority (Highest priority: 7)
HDR_PKT_CFI	Header Packet VLAN CFI bit.
HDR_PKT_Vid	Header Packet VLAN ID
PKT_Type	Packet Type. Indicates whether the packet is VLAN-tagged, priority-tagged, or non-tagged. 00: VLAN-tagged packet 01: Reserved 10: Priority-tagged packet 11: Non-tagged packet

15.3.2.6 VLAN Unaware Mode

The CPSW_3G is in VLAN unaware mode when the CPSW Control register vlan_aware bit is cleared. Port 0 receive packets (out of the CPSW_3G) may or may not be VLAN encapsulated depending on the CPSW Control register rx_vlan_encap bit. Port 0 transmit packets are never VLAN encapsulated.

15.3.2.7 Address Lookup Engine (ALE)

The address lookup engine (ALE) processes all received packets to determine which port(s) if any that the packet should the forwarded to. The ALE uses the incoming packet received port number, destination address, source address, length/type, and VLAN information to determine how the packet should be forwarded. The ALE outputs the port mask to the switch fabric that indicates the port(s) the packet should be forwarded to. The ALE is enabled when the ale_enable bit in the ALE_Ctrl register is set. All packets are dropped when the ale_enable bit is cleared to zero.

In normal operation, the CPGMAC_SL modules are configured to issue an abort, instead of an end of packet, at the end of a packet that contains an error (runt, frag, oversize, jabber, crc, alignment, code etc.) or at the end of a mac control packet. However, when the CPGMAC_SL configuration bit(s) cef, csf, or cmf are set, error frames, short frames or mac control frames have a normal end of packet instead of an abort at the end of the packet. When the ALE receives a packet that contains errors (due to a set header error bit), or a mac control frame and does not receive an abort, the packet will be forwarded only to the host port (port 0). No ALE learning occurs on packets with errors or mac control frames. Learning is based on source address and lookup is based on destination address.

The ALE may be configured to operate in bypass mode by setting the ale_bypass bit in the ALE_Ctrl register. When in bypass mode, all CPGMAC_SL received packets are forwarded only to the host port (port 0). Packets from the two ports can be on separate Rx DMA channels by configuring the CPDMA_Rx_Ch_Map register. In bypass mode, the ALE processes host port transmit packets the same as in normal mode. In general, packets would be directed by the host in bypass mode.

The ALE may be configured to operate in OUI deny mode by setting the enable_oui_deny bit in the ALE_Ctrl register. When in OUI deny mode, a packet with a non-matching OUI source address will be dropped unless the destination address matches a multicast table entry with the super bit set. Broadcast packets will be dropped unless the broadcast address is entered into the table with the super bit set. Unicast packets will be dropped unless the unicast address is in the table with block and secure both set (supervisory unicast packet).

Multicast supervisory packets are designated by the super bit in the table entry. Unicast supervisory packets are indicated when block and secure are both set. Supervisory packets are not dropped due to rate limiting, OUI, or VLAN processing.

15.3.2.7.1 Address Table Entry

The ALE table contains 1024 entries. Each table entry represents a free entry, an address, a VLAN, an address/VLAN pair, or an OUI address. Software should ensure that there are not double address entries in the table. The double entry used would be indeterminate. Reserved table bits must be written with zeroes.

Source Address learning occurs for packets with a unicast, multicast or broadcast destination address and a unicast or multicast (including broadcast) source address. Multicast source addresses have the group bit (bit 40) cleared before ALE processing begins, changing the multicast source address to a unicast source address. A multicast address of all ones is the broadcast address which may be added to the table. A learned unicast source address is added to the table with the following control bits:

Table 15-9. Learned Address Control Bits

unicast_type	11
Block	0
Secure	0

If a received packet has a source address that is equal to the destination address then the following occurs:

- The address is learned if the address is not found in the table.
- The address is updated if the address is found.
- The packet is dropped.

15.3.2.7.1.1 Free Table Entry

Table 15-10. Free (Unused) Address Table Entry Bit Values

71:62	61:60	59:0
Reserved	Entry Type (00)	Reserved

15.3.2.7.1.2 Multicast Address Table Entry

Table 15-11. Multicast Address Table Entry Bit Values

71:70	68:66	65	64	63:62	61:60	59:48	47:0
Reserved	Port Mask	Super	Reserved	Mcast Fwd State	Entry Type (01)	Reserved	Multicast Address

Table Entry Type

00: Free Entry

01: Address Entry : unicast or multicast determined by dest **address bit 40 .**

10: VLAN entry

11: VLAN Address Entry : unicast or multicast determined by **address bit 40.**

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(2:0) (PORT_MASK)

This three bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Multicast Forward State – Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit port_mask has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00: Forwarding

01: Blocking/Forwarding/Learning

10: Forwarding/Learning

11: Forwarding

The forward state test returns a true value if both the Rx and Tx ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

15.3.2.7.1.3 VLAN/Multicast Address Table Entry

Table 15-12. VLAN/Multicast Address Table Entry Bit Values

71:69	68:66	65	64	63:62	61:60	59:48	47:0
Reserved	Port Mask	Super	Reserved	Mcast Fwd State	Entry Type (11)	vlan_id	Multicast Address

Supervisory Packet (SUPER)

When set, this field indicates that the packet with a matching multicast destination address is a supervisory packet.

0: Non-supervisory packet

1: Supervisory packet

Port Mask(2:0) (PORT_MASK)

This three bit field is the port bit mask that is returned with a found multicast destination address. There may be multiple bits set indicating that the multicast packet may be forwarded to multiple ports (but not the receiving port).

Multicast Forward State (MCAST_FWD_STATE)

Multicast Forward State – Indicates the port state(s) required for the received port on a destination address lookup in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state in order to forward the packet. If the transmit port_mask has multiple set bits then each forward decision is independent of the other transmit port(s) forward decision.

00 – Forwarding

01 – Blocking/Forwarding/Learning

10 – Forwarding/Learning

11 – Forwarding

The forward state test returns a true value if both the Rx and Tx ports are in the required state.

Table Entry Type (ENTRY_TYPE)

Address entry type. Unicast or multicast determined by address bit 40.

11: VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (MULTICAST_ADDRESS)

This is the 48-bit packet MAC address. For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup. Otherwise, all 48-bits are used in the lookup.

15.3.2.7.1.4 Unicast Address Table Entry

Table 15-13. Unicast Address Table Entry Bit Values

71:70	69	68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	DLR Unicast	Reserved	Port Number	Block	Secure	Unicast Type (00) or (X1)	Entry Type (01)	Reserved	Unicast Address

DLR Unicast

DLR Unicast – When set, this bit indicates that the address is a Device Level Ring (DLR) unicast address. Received packets with a matching destination address will be flooded to the vlan_member_list (minus the receive port and the host port). The port_number field is a don’t care when this bit is set. Matching packets received on port 1 egress on port 2. Matching packets received on port 2 egress on port 1. Matching packets received on port 0 egress on ports 1 and 2.

Port Number (PORT_NUMBER)

Port Number – This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).

Block (BLOCK)

Block – The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 – Address is not blocked.

1 – Drop a packet with a matching source or destination address (secure

must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

Secure – This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port_number.

0 – Received port number is a don't care.

1 – Drop the packet if the received port is not the secure port for the source

address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

Unicast Type – This field indicates the type of unicast address the table entry contains.

00 – Unicast address that is not ageable.

01 – Ageable unicast address that has not been touched.

10 – OUI address - lower 24-bits are don't cares (not ageable).

11 – Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

15.3.2.7.1.5 OUI Unicast Address Table Entry

Table 15-14. OUI Unicast Address Table Entry Bit Values

71:64	63:62	61:60	59:48	47:24	23:0
Reserved	Unicast Type (10)	Entry Type (01)	Reserved	Unicast OUI	Reserved

Unicast Type (UNICAST_TYPE)

Unicast Type – This field indicates the type of unicast address the table entry contains.

00 – Unicast address that is not ageable.

01 – Ageable unicast address that has not been touched.

10 – OUI address - lower 24-bits are don't cares (not ageable).

11 – Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

01: Address entry. Unicast or multicast determined by address bit 40.

Packet Address (UNICAST_OUI)

For an OUI address, only the upper 24-bits of the address are used in the source or destination address lookup.

15.3.2.7.1.6 VLAN/Unicast Address Table Entry

Table 15-15. Unicast Address Table Entry Bit Values

71:68	67:66	65	64	63:62	61:60	59:48	47:0
Reserved	Port Number	Block	Secure	Unicast Type (00) or (X1)	Entry Type (11)	vlan_id	Unicast Address

Port Number (PORT_NUMBER)

Port Number – This field indicates the port number (not port mask) that the packet with a unicast destination address may be forwarded to. Packets with unicast destination addresses are forwarded only to a single port (but not the receiving port).]

Block (BLOCK)

Block – The block bit indicates that a packet with a matching source or destination address should be dropped (block the address).

0 – Address is not blocked.

1 – Drop a packet with a matching source or destination address (secure

must be zero)

If block and secure are both set, then they no longer mean block and secure. When both are set, the block and secure bits indicate that the packet is a unicast supervisory (super) packet and they determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state.

Secure (SECURE)

Secure – This bit indicates that a packet with a matching source address should be dropped if the received port number is not equal to the table entry port_number.

0 – Received port number is a don’t care.

1 – Drop the packet if the received port is not the secure port for the source

address and do not update the address (block must be zero)

Unicast Type (UNICAST_TYPE)

Unicast Type – This field indicates the type of unicast address the table entry contains.

00 – Unicast address that is not ageable.

01 – Ageable unicast address that has not been touched.

10 – OUI address - lower 24-bits are don’t cares (not ageable).

11 – Ageable unicast address that has been touched.

Table Entry Type (ENTRY_TYPE)

Address entry. Unicast or multicast determined by address bit 40.

11 – VLAN address entry. Unicast or multicast determined by address bit 40.

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Packet Address (UNICAST_ADDRESS)

This is the 48-bit packet MAC address. All 48-bits are used in the lookup.

15.3.2.7.1.7 VLAN Table Entry

Table 15-16. VLAN Table Entry

71:62	61:60	59:48	47:27	26:24	23:19	18:16	15:11	10:8	7:3	2:0
Reserved	Entry Type (10)	vlan_id	Reserved	Force Untagged Egress	Reserved	Reg Mcast Flood Mask	Reserved	Unreg Mcast Flood Mask	Reserved	Vlan Member List

Table Entry Type (ENTRY_TYPE)

10: VLAN entry

VLAN ID (VLAN_ID)

The unique identifier for VLAN identification. This is the 12-bit VLAN ID.

Force Untagged Packet Egress (FORCE_UNTAGGED_EGRESS)

This field causes the packet VLAN tag to be removed on egress (except on port 0).

Registered Multicast Flood Mask (REG_MCAST_FLOOD_MASK)

Mask used for multicast when the multicast address is found

Unregistered Multicast Flood Mask (UNREG_MCAST_FLOOD_MASK)

Mask used for multicast when the multicast address is not found

VLAN Member List (VLAN_MEMBER_LIST)

This three bit field indicates which port(s) are members of the associated VLAN.

15.3.2.7.2 Packet Forwarding Processes

There are four processes that an incoming received packet may go through to determine packet forwarding. The processes are Ingress Filtering, VLAN_Aware Lookup, VLAN_Unaware Lookup, and Egress.

Packet processing begins in the Ingress Filtering process. Each port has an associated packet forwarding state that can be one of four values (Disabled, Blocked, Learning, or Forwarding). The default state for all ports is disabled. The host sets the packet forwarding state for each port. The receive packet processes are described in the following sections.

In the packet ingress process (receive packet process), there is a forward state test for unicast destination addresses and a forward state test for multicast addresses. The multicast forward state test indicates the port states required for the receiving port in order for the multicast packet to be forwarded to the transmit port(s). A transmit port must be in the Forwarding state for the packet to be forwarded for transmission. The mcast_fwd_state indicates the required port state for the receiving port as indicated in Table 15-12.

The unicast forward state test indicates the port state required for the receiving port in order to forward the unicast packet. The transmit port must be in the Forwarding state in order to forward the packet. The block and secure bits determine the unicast forward state test criteria. If both bits are set then the packet is forwarded if the receive port is in the Forwarding/Blocking/Learning state. If both bits are not set then the packet is forwarded if the receive port is in the Forwarding state. The transmit port must be in the Forwarding state regardless. The forward state test used in the ingress process is determined by the destination address packet type (multicast/unicast).

In general, packets received with errors are dropped by the address lookup engine without learning, updating, or touching the address. The error condition and the abort are indicated by the CPGMAC_SL to the ALE. Packets with errors may be passed to the host (not aborted) by a CPGMAC_SL port if the port has a set rx_cmf_en, rx_cef_en, or rx_csf_en bit(s).

Error packets that are passed to the host by the CPGMAC_SL are considered to be bypass packets by the ALE and are sent only to the host. Error packets do not learn, update, or touch addresses regardless of whether they are aborted or sent to the host. Packets with errors received by the host are forwarded as normal.

The following control bits are in the CPGMAC_SL1/2_MACCTRL register.

rx_cef_en: This CPGMAC_SL control bit enables frames that are fragments, long, jabber, CRC, code, and alignment errors to be forwarded.

rx_csf_en: This CPGMAC_SL bit enables short frames to be forwarded.

rx_cmf_en: This CPGMAC_SL control bit enables mac control frames to be forwarded.

15.3.2.7.2.1 Ingress Filtering Process

```
If (Rx port_state is Disabled)
then discard the packet

if (directed packet)
then use directed port number and go to Egress process

if ((ale_bypass or error packet) and (host port is not the receive port))
then use host portmask and go to Egress process

if (((block) and (unicast source address found)) or ((block) and (unicast destination address found)))
then discard the packet

if ((enable_rate_limit) and (rate limit exceeded) and (not rate_limit_tx)
then if (((mcast/bcast destination address found) and (not super)) or (mcast/bcast destination address not found))
  then discard the packet

if ((not forward state test valid) and (destination address found))
then discard the packet to any port not meeting the requirements
  • Unicast destination addresses use the unicast forward state test and multicast destination addresses use the multicast forward
    state test.

if ((destination address not found) and ((not transmit port forwarding) or (not receive port forwarding)))
then discard the packet to any ports not meeting the above requirements

if (source address found) and (secure) and (receive port number != port_number))
then discard the packet

if ((not super) and (drop_untagged) and ((non-tagged packet) or ((priority tagged) and not(en_vid0_mode))
then discard the packet

If (VLAN_Unaware)

  then portmask is the logical “AND” of unreg_mcast_flood_mask and vlan_member_list
  then goto Egress process

if (Broadcast packet)
  then use found vlan_member_list and goto Egress process
```

15.3.2.7.2.4 Egress Process

Clear Rx port from portmask (don’t send packet to Rx port).
Clear disabled ports from portmask.
if ((enable_oui_deny) and (OUI source address not found) and (not ale_bypass) and (not error packet) and not ((mcast destination address) and (super))) then Clear host port from portmask
if ((enable_rate_limit) and (rate_limit_tx)) then if (not super) and (rate limit exceeded on any tx port) then clear rate limited tx port from portmask If address not found then super cannot be set.
If portmask is zero then discard packet
Send packet to portmask ports.

15.3.2.7.3 Learning/Updating/Touching Processes

The learning, updating, and touching processes are applied to each receive packet that is not aborted. The processes are concurrent with the packet forwarding process. In addition to the following, a packet must be received without error in order to learn/update/touch an address.

15.3.2.7.3.1 Learning Process

If (not(Learning or Forwarding) or (enable_auth_mode) or (packet error) or (no_learn)) then do not learn address
if ((Non-tagged packet) and (drop_untagged)) then do not learn address
if ((vlan_aware) and (VLAN not found) and (unknown_vlan_member_list = “000”)) then do not learn address
if ((vid_ingress_check) and (Rx port is not VLAN member) and (VLAN found)) then do not learn address
if ((source address not found) and (vlan_aware) and not(learn_no_vid)) then learn address with VLAN
if ((source address not found) and ((not vlan_aware) or (vlan_aware and learn_no_vid))) then learn address without VLAN

15.3.2.7.3.2 Updating Process

if (dlr_unicast) then do not update address
If (not(Learning or Forwarding) or (enable_auth_mode) or (packet error) or (no_sa_update)) then do not update address
if ((Non-tagged packet) and (drop_untagged)) then do not update address
if ((vlan_aware) and (VLAN not found) and (unknown_vlan_member_list = “000”)) then do not update address
if ((vid_ingress_check) and (Rx port is not VLAN member) and (VLAN found)) then do not update address
if ((source address found) and (receive port number != port_number) and (secure or block)) then do not update address

```
if ((source address found) and (receive port number != port_number))
then update address
```

15.3.2.7.3.3 Touching Process

```
if ((source address found) and (ageable) and (not touched))
then set touched
```

15.3.2.8 Packet Priority Handling

Packets are received on three ports, two of which are CPGMAC_SL Ethernet ports and the third port is the CPPI host port. Received packets have a received packet priority (0 to 7 with 7 being the highest priority). The received packet priority is determined as shown:

1. If the first packet LTYPE = 0x8100 then the received packet priority is the packet priority (VLAN tagged and priority tagged packets).
2. If the first packet LTYPE = 0x0800 and byte 14 (following the LTYPE) is equal to 0x45 then the received packet priority is the 6-bit TOS field in byte 15 (upper 6-bits) mapped through the port’s DSCP priority mapping register (IPV4 packet).
3. The received packet priority is the source (ingress) port priority (untagged non-IPV4 packet).

The received packet priority is mapped through the receive ports associated “packet priority to header packet priority mapping register” to obtain the header packet priority (the CPDMA Rx and Tx nomenclature is reversed from the CPGMAC_SL nomenclature for legacy reasons). The header packet priority is mapped through the “header priority to switch priority mapping register” to obtain the hardware switch priority (0 to 3 with 3 being the highest priority). The header packet priority is then used as the actual transmit packet priority if the VLAN information is to be sent on egress.

15.3.2.9 FIFO Memory Control

Each of the three CPSW_3G ports has an identical associated FIFO. Each FIFO contains a single logical receive (ingress) queue and four logical transmit queues (priority 0 through 3). Each FIFO memory contains 20,480 bytes (20k) total organized as 2560 by 64-bit words contained in a single memory instance. The FIFO memory is used for the associated port transmit and receive queues. The tx_max_blks field in the FIFO’s associated Max_Blks register determines the maximum number of 1k FIFO memory blocks to be allocated to the four logical transmit queues (transmit total).

The rx_max_blks field in the FIFO’s associated Max_Blks register determines the maximum number of 1k memory blocks to be allocated to the logical receive queue. The tx_max_blks value plus the rx_max_blks value must sum to 20 (the total number of blocks in the FIFO). If the sum were less than 20 then some memory blocks would be unused.The default is 17 (decimal) transmit blocks and three receive blocks. The FIFO’s follow the naming convention of the Ethernet ports.Host Port is Port0 and External Ports are Port1,2

15.3.2.10 FIFO Transmit Queue Control

There are four transmit queues in each transmit FIFO. Software has some flexibility in determining how packets are loaded into the queues and on how packet priorities are selected for transmission (how packets are removed and transmitted from queues). All ports on the switch have identical FIFO’s. For the purposes of the below the transmit FIFO is switch egress even though the port 0 transmit FIFO is connected to the CPDMA receive (also switch egress). The CPDMA nomenclature is reversed from the CPGMAC_SL nomenclature due to legacy reasons.

15.3.2.10.1 Normal Priority Mode

When operating in normal mode, lower priority frames are dropped before higher priority frames. The intention is to give preference to higher priority frames. Priority 3 is the highest priority and is allowed to fill the FIFO. Priority 2 will drop packets if the packet is going to take space in the last 2k available. Priority 1 will drop packets if the packet is going to take space in the last 4k available. Priority 0 will drop packets if the packet is going to take space in the last 6k available. If fewer than 4 priorities are to be implemented then the priorities should be mapped such that the highest priorities are used.

For example, if two priorities are going to be used then all packets should be mapped to priorities 3 and 2 and priorities 1 and 0 should be unused. Priority escalation may be used in normal priority mode if desired. Normal priority mode is configured as described below:

- Select normal priority mode by setting tx_in_sel[1:0] = 00 for all ports (default value in P0/1/2_Tx_In_Ctl)
- Configure priority mapping to use only the highest priorities if less than 4 priorities are used. Refer to the Packet Priority Handling section of this chapter.

15.3.2.10.2 Dual Mac Mode

When operating in dual mac mode the intention is to transfer packets between ports 0 and 1 and ports 0 and 2, but not between ports 1 and 2. Each CPGMAC_SL appears as a single MAC with no bridging between MAC’s. Each CPGMAC_SL has at least one unique (not the same) mac address.

Dual mac mode is configured as described below:

- Set the ale_vlan_aware bit in the ALE_Ctrl register. This bit configures the ALE to process in vlan aware mode.The CPSW_3G vlan aware bit (vlan_aware in CPSW_Ctrl) determines how packets VLAN’s are processed on CPGMAC_SL egress and does not affect how the ALE processes packets or the packet destination. The CPSW_3G vlan aware bit may be set or not as required (must be set if VLAN’s are to exit the switch).
- **Configure the Port 1 to Port 0 VLAN**

Add a VLAN Table Entry with ports 0 and 1 as members (clear the flood masks).

Add a VLAN/Unicast Address Table Entry with the Port1/0 VLAN and a port number of 0. Packets received on port 1 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.

- **Configure the Port 2 to Port 0 VLAN**

Add a VLAN Table Entry with ports 0 and 2 as members (clear the flood masks).

Add a VLAN/Unicast Address Table Entry with the Port2/0 VLAN and a port number of 0. Packets received on port 2 with this unicast address will be sent only to port 0 (egress). If multiple mac addresses are desired for this port then multiple entries of this type may be configured.

- Packets from the host (port 0) to ports 1 and 2 should be directed. If directed packets are not desired then VLAN with addresses can be added for both destination ports.
- Select the dual mac mode on the port 0 FIFO by setting tx_in_sel[1:0] = 01 in P0_Tx_In_Ctl. The intention of this mode is to allow packets from both ethernet ports to be written into the FIFO without one port starving the other port.
- The priority levels may be configured such that packets received on port 1 egress on one CPDMA RX channel while packets received on port 2 egress on a different CPDMA RX channel.

15.3.2.10.3 Rate Limit Mode

Rate-limit mode is intended to allow some CPDMA transmit (switch ingress) channels and some CPGMAC_SL FIFO priorities (switch egress) to be rate-limited. Non rate-limited traffic (bulk traffic) is allowed on non rate-limited channels and FIFO priorities. The bulk traffic does not impact the rate-limited traffic. Rate-limited traffic must be configured to be sent to rate-limited queues (via packet priority handling).

The allocated rates for rate-limited traffic must not be oversubscribed. For example, if port 1 is sending 15% rate limited traffic to port 2 priority 3, and port 0 is also sending 10% rate-limited traffic to port 2 priority 3, then the port 2 priority 3 egress rate must be configured to be 25% plus a percent or two for margin. The switch must be configured to allow some percentage of non rate-limited traffic. Non-rate-limited traffic must be configured to be sent to non rate-limited queues. No packets from the host should be dropped, but non rate-limited traffic received on an ethernet port can be dropped. Rate-limited mode is configured as shown:

- Set tx_in_sel[1:0] = 10 in P1/2_Tx_In_Ctl to enable ports 1 and 2 transmit FIFO inputs to be configured for rate-limiting queues. Enabling a queue to be rate-limiting with this field affects only the packet being loaded into the FIFO, it does not configure the transmit for queue shaping.
- Configure the number of rate-limited queues for port 1 and 2 transmit FIFO’s by setting the tx_rate_en[3:0] field in P1/2_Tx_In_Ctl. Rate limited queues must be the highest number. For example, if there are two rate limited queues then 1100 would be written to this field for priorities 3 and 2. This field enables the FIFO to allow rate-limited traffic into rate-limited queues while discriminating against non rate-limited queues.
- Set p1_priN_shape_en and p2_priN_shape_en in the CPSW_3G PTYPE register. These bits determine which queues actually shape the output data stream. In general, the same priorities that are set in tx_rate_en are set in these bits as well, but the FIFO input and output enable bits are separate to allow rate-limiting from the host to non shaped channels if desired.
  When queue shaping is not enabled for a queue then packets are selected for egress based on priority. When queue shaping is enabled then packets are selected for egress based on queue percentages. If shaping is required on a single queue then it must be priority 3 (priorities 2, 1 and 0 are strict priority). If shaping is required on two queues then it must be on priorities 2 and 3 (priorities 1 and 0 are strict priority). If shaping is required on three queues then it must be priorities 3, 2, and 1 (priority 0 would then get the leftovers). Priority shaping follows the requirements in the IEEE P802.1Qav/D6.0 specification. Priority shaping is not compatible with priority escalation (escalation must be disabled).
- P0_Tx_In_Ctl[1:0] should remain at the default 00 value. Port 0 egress (CPDMA RX) should not be rate-limited.
- The CPDMA is configured for rate-limited transmit (switch ingress) channels by setting the highest bits of the tx_rlim[7:0] field in the CPDMA DMA_Ctrl register. If there are two rate limited channels then tx_rlim[7:0] = 11000000 (the rate limited channels must be the highest priorities). Also, tx_ptype in the DMA_Ctrl register must be set (fixed priority mode). Rate limited channels must go to rate-limited FIFO queues, and the FIFO queue rate must not be oversubscribed.

15.3.2.11 Packet Padding

VLAN tagged ingress packets of 64 to 67-bytes will be padded to 64-bytes on egress (all ports) if the VLAN is removed on egress.

15.3.2.12 Flow Control

There are two types of switch flow control – CPPI port flow control and Ethernet port flow control. The CPPI and Ethernet port naming conventions for data flow into and out of the switch are reversed. For the CPPI port (port 0), transmit operations move packets from external memory into the switch and then out to either or both Ethernet transmit ports (ports 1 and 2). CPPI receive operations move packets that were received on either or both Ethernet receive ports to external memory.

15.3.2.12.1 CPPI Port Flow Control

The CPPI port has flow control available for transmit (switch ingress). CPPI receive operations (switch egress) do not require flow control. CPPI Transmit flow control is initiated when enabled and triggered. CPPI transmit flow control is enabled by setting the p0_flow_en bit in the **CPSW_Flow_Ctrl** register. CPPI transmit flow control is enabled by default on reset because host packets should not be dropped in any mode of operation.

15.3.2.12.2 Ethernet Port Flow Control

The Ethernet ports have flow control available for transmit and receive. Transmit flow control stops the Ethernet port from transmitting packets to the wire (switch egress) in response to a received pause frame. Transmit flow control does not depend on FIFO usage.

The ethernet ports have flow control available for receive operations (packet ingress). Ethernet port receive flow control is initiated when enabled and triggered. Packets received on an ethernet port can be sent to the other ethernet port or the CPPI port (or both). Each destination port can trigger the receive ethernet port flow control. An ethernet destination port triggers another ethernet receive flow control when the destination port is full.

When a packet is received on an ethernet port interface with enabled flow control the below occurs:

- The packet will be sent to all ports that currently have room to take the entire packet.
- The packet will be retried until successful to all ports that indicate they don’t have room for the packet.

The flow control trigger to the CPGMAC_SL will be asserted until the packet has been sent, and there is room in the logical receive FIFO for packet runout from another flow control trigger (**rx_pkt_cnt** = 0). Ethernet port receive flow control is disabled by default on reset. Ethernet port receive flow control requires that the **rx_flow_en** bit in the associated CPGMAC_SL be set to one.

When receive flow control is enabled on a port, the port’s associated FIFO block allocation must be adjusted. The port RX allocation must increase from the default three blocks to accommodate the flow control runout. A corresponding decrease in the TX block allocation is required. If a sending port ignores a pause frame then packets may overrun on receive (and be dropped) but will not be dropped on transmit. If flow control is disabled for gmii ports, then any packets that are dropped are dropped on transmit and not on receive.

15.3.2.12.2.1 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the CPGMAC_SL from further frame reception. Half-duplex mode receive flow control is collision based while full duplex mode issues 802.3X pause frames. In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control is enabled by the **rx_flow_en** bit in the **MACCTRL** register. Receive flow control is triggered (when enabled) when the **RX_FLOW_TRIGGER** input is asserted. The CPGMAC_SL is configured for collision or IEEE 802.3X flow control via the **fullduplex** bit in the **MACCTRL** register.

15.3.2.12.2.1.1 Collision Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the port is operating in half-duplex mode (**fullduplex** is cleared in **MACCTRL)**. When receive flow control is enabled and triggered, the port will generate collisions for received frames. The jam sequence transmitted will be the twelve byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3 (hex). The jam sequence will begin no later than approximately as the source address starts to be received. Note that these forced collisions will not be limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm. Receive flow control does not depend on the value of the incoming frame destination address. A collision will be generated for any incoming packet, regardless of the destination address.

15.3.2.12.2.1.2 IEEE 802.3X Based Receive Flow Control

IEEE 802.3x based receive flow control provides a means of preventing frame reception when the port is operating in full-duplex mode (**fullduplex** is set in **MACCTRL)**. When receive flow control is enabled and triggered, the port will transmit a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The CPGMAC_SL will transmit a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle, or following the completion of the frame currently being transmitted). The pause frame will contain the maximum possible value for the pause time (0xFFFF). The MAC will count the receive pause frame time (decrements 0xFF00 downto zero) and retransmit an outgoing pause frame if the count reaches zero. When the flow control request is removed, the MAC will transmit a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval will be received normally (provided the Rx FIFO is not full).

Pause frames will be transmitted if enabled and triggered regardless of whether or not the port is observing the pause time period from an incoming pause frame.

The CPGMAC_SL will transmit pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01.
- The 48-bit source address — SL_SA(47:0).
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause time value FF.FF. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request will have a pause time value of 00.00.
- Zero padding to 64-byte data length (The CPGMAC_SL will transmit only 64 byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

If **rx_flow_en** is cleared to zero while the pause time is nonzero, then the pause time will be cleared to zero and a zero count pause frame will be sent.

15.3.2.12.2.2 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the CPGMAC_SL from transmitting any further frames. Incoming pause frames are only acted upon when the **fullduplex** and **tx_flow_en** bits in the **MACCTRL** register are set. Pause frames are not acted upon in half-duplex mode. Pause frame action will be taken if enabled, but normally the frame will be filtered and not transferred to memory.

MAC control frames will be transferred to memory if the **rx_cmf_en** (Copy MAC Frames) bit in the **MACCTRL** register is set. The **tx_flow_en** and **fullduplex** bits effect whether or not MAC control frames are acted upon, but they have no effect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MACCTRL Frames with an opcode field=0x0001. Incoming pause frames will only be acted upon by the port if:

- **tx_flow_en** is set in **MACCTRL**, and
- the frame’s length is 64 to **rx_maxlen** bytes inclusive, and
- the frame contains no crc error or align/code errors.

The pause time value from valid frames will be extracted from the two bytes following the opcode. The pause time will be loaded into the port’s transmit pause timer and the transmit pause time period will begin.

If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- if the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer will immediately expire, or
- if the new pause time value is zero then the transmit pause timer will immediately expire, else
- the port transmit pause timer will immediately be set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame will be discarded).

If **tx_flow_en** in **MACCTRL** is cleared, then the pause-timer will immediately expire.

The port will not start the transmission of a new data frame any sooner than 512-bit times after a pause frame with a non-zero pause time has finished being received (**GMII_RXDV** going inactive). No transmission will begin until the pause timer has expired (the port may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received will be completed and unaffected.

Incoming pause frames consist of the below:

- A 48-bit destination address equal to:
- The reserved multicast destination address 01.80.C2.00.00.01, or
- The SL_SA(47:0) input mac source address.
- The 48-bit source address of the transmitting device.
- The 16-bit length/type field containing the value 88.08
- The 16-bit pause opcode equal to 00.01
- The 16-bit pause_time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities above are hexadecimal and are transmitted most-significant byte first. The least-significant bit is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The CPGMAC_SL will recognize any pause frame between 64 bytes and **rx_maxlen** bytes in length.

15.3.2.13 Packet Drop Interface

The packet drop interface supports an external packet drop engine. The port 1 (and port 2) CPGMAC_SL receive FIFO VBUSP interface signals are CPSW_3G outputs. The receive packet interface has an associated packet drop input P1_RFIFO_DROP (P2_RFIFO_DROP). An external packet drop engine may “snoop” the received packet header and data to determine whether or not the packet should be dropped.

If the packet is to be dropped the external logic must assert the drop signal by no later than the second clock after the end of packet (or abort) indication from the CPGMAC_SL. The drop signal should remain asserted until the second clock after the end of packet (or abort) indication. If the packet is not to be dropped then the drop signal should remain deasserted. The CPGMAC_SL section contains more information on the receive FIFO VBUSP interface signals and end of packet indication.

15.3.2.14 Short Gap

The port 1 (and port 2) transmit inter-packet gap (IPG) may be shortened by eight bit times when enabled and triggered. The **tx_short_gap_en** bit in the **SL1_MACCTRL (SL2_MACCTRL)** register enables the gap to be shortened when triggered. The condition is triggered when the port 1 (port 2) transmit FIFO has a user defined number of FIFO blocks used. The port 1 transmit FIFO blocks used determines if the port 1 gap is shortened, and the port 2 transmit FIFO blocks used determines if the port 2 gap is shortened. The **CPSW_Gap_Thresh** register value determines the port 1 short gap threshold, and the **CPSW_Gap_Thresh** register value determines the port 2 short gap threshold.

15.3.2.15 Switch Latency

The CPSW_3G is a store and forward switch. The switch latency is defined as the amount of time between the end of packet reception of the received packet to the start of the output packet transmit.

Mode	Latency
Gig (1000)	880ns
100	1.3us
10	6.5us

15.3.2.16 Emulation Control

The emulation control input (EMUSUSP) and submodule emulation control registers allow CPSW_3G operation to be completely or partially suspended. There are three CPSW_3G submodules that contain emulation control registers (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). The submodule emulation control registers must be accessed to facilitate CPSW_3G emulation control. The CPSW_3G module enters the emulation suspend state if all three submodules are configured for emulation suspend and the emulation suspend input is asserted.

A partial emulation suspend state is entered if one or two submodules is configured for emulation suspend and the emulation suspend input is asserted. Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

CPGMAC_SL Emulation Control

The emulation control input (**TBEMUSUP**) and register bits (**soft** and **free** in the **EMCTRL** register) allow CPGMAC_SL operation to be suspended. When the emulation suspend state is entered, the CPGMAC_SL will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For receive, frames that are detected by the CPGMAC_SL after the suspend state is entered are ignored. Emulation control is implemented for compatibility with other peripherals.

CPDMA Emulation Control

The emulation control input (**TBEMUSUP**) and register bits (**soft** and **free** in the **EMCTRL** register) allow CPDMA operation to be suspended. When the emulation suspend state is entered, the CPDMA will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the tx cell fifo will be transmitted. For receive, frames that are detected by the CPDMA after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Emulation control is implemented for compatibility with other peripherals.

The following table shows the operations of the emulation control input and register bits:

Table 15-17. Operations of Emulation Control Input and Register Bits

EMUSUSP	soft	free	Description
0	X	X	Normal Operation
1	0	0	Normal Operation
1	1	0	Emulation Suspend
1	X	1	Normal Operation

Emulation Suspend Input

The emulation suspend input described above comes from the Debug Subsystem. See Chapter 31, *Debug Subsystem*, to enable an emulation suspend event input for the Ethernet Subsystem (EMAC).

15.3.2.17 Software IDLE

The submodule software idle register bits enable CPSW_3G operation to be completely or partially suspended by software control. There are three CPSW_3G submodules that contain software idle register bits (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). Each of the three submodules may be individually commanded to enter the idle state. The idle state is entered at packet boundaries, and no further packet operations will occur on an idled submodule until the idle command is removed. The CPSW_3G module enters the idle state when all three submodules are commanded to enter and have entered the idle state. Idle status is determined by reading or polling the three submodule idle bits. The CPSW_3G is in the idle state when all three submodules are in the idle state. The **CPSW_Soft_Idle** bit may be set if desired after the submodules are in the idle state. The **CPSW_Soft_Idle** bit causes packets to not be transferred from one FIFO to another FIFO internal to the switch.

15.3.2.18 Software Reset

The CPSW_3G software reset register, CPSW_3GSS software reset register and the three submodule software reset registers enable the CPSW_3GSS to be reset by software. There are three CPSW_3G submodules that contain software reset registers (CPGMAC_SL1, CPGMAC_SL2, and CPDMA). Each of the three submodules may be individually commanded to be reset by software.

For the CPDMA, the reset state is entered at packet boundaries, at which time the CPDMA reset occurs. The CPGMAC_SL soft reset is immediate. Submodule reset status is determined by reading or polling the submodule reset bit. If the submodule reset bit is read as a one, then the reset process has not yet completed. The submodule soft reset process could take up to 2ms each. The reset has completed if the submodule reset bit is read as a zero.

After all three submodules (in any order) have been reset and a read of each submodule reset bit indicates that the reset process is complete, the CPSW_3G software reset register bit may be written to complete the CPSW_3G module software reset operation. The CPSW_3G software reset bit controls the reset of the FIFO's, the statistics submodule, and the address lookup engine (ALE). The CPSW_3G software reset is immediate and will be indicated by reading a zero from the soft reset bit.

The CPSW_3GSS software reset bit controls the reset of the INT, REGS and CPPI. The CPSW_3GSS software reset is immediate and will be indicated by reading a zero from the soft reset bit.

15.3.2.19 FIFO Loopback

FIFO loopback mode is entered when the fifo_loopback bit in the CPSW_Ctrl register is set. FIFO loopback mode causes packets received on a port to be turned around and transmitted back on the same port. Port 0 receive is fixed on channel zero in FIFO loopback mode. The RXSOFOVERRUN statistic is incremented for each packet sent in FIFO loopback mode. Packets sent in with errors are returned with errors (they are not dropped). FIFO loopback is intended as a simple mechanism for test purposes. FIFO loopback should be performed in fullduplex mode only.

15.3.2.20 CPSW_3G Network Statistics

The CPSW_3G has a set of statistics that record events associated with frame traffic on selected switch ports. The statistics values are cleared to zero 38 clocks after the rising edge of VBUSP_RST_N. When one or more port enable bits (stat_port_en[2:0]) are set, all statistics registers are write to decrement. The value written will be subtracted from the register value with the result being stored in the register. If a value greater than the statistics value is written, then zero will be written to the register (writing 0xffffffff will clear a statistics location).

When all port enable bits are cleared to zero, all statistics registers are read/write (normal write direct, so writing 0x00000000 will clear a statistics location). All write accesses must be 32-bit accesses. In the below statistics descriptions, “the port” refers to any enabled port (with a corresponding set stat_port_en[2:0] bit).

The statistics interrupt (STAT_PEND) will be issued if enabled when any statistics value is greater than or equal to 0x80000000. The statistics interrupt is removed by writing to decrement any statistics value greater than 0x80000000. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from 0xFFFFFFFF to 0x00000000.

15.3.2.20.1 Rx-only Statistics Descriptions

15.3.2.20.1.1 Good Rx Frames (Offset = 0h)

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Had a length of 64 to rx_maxlen bytes inclusive
- Had no CRC error, alignment error or code error.

For definitions of alignment, code and CRC errors, see Section 15.3.2.20.1.5, *Rx CRC Errors* and Section 15.3.2.20.1.6, *Rx Align/Code Errors*. Overruns have no effect upon this statistic.

15.3.2.20.1.2 Broadcast Rx Frames (Offset = 4h)

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for only address 0xFFFFFFFFFFFF
- Had a length of 64 to rx_maxlen bytes inclusive
- Had no CRC error, alignment error or code error.

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

15.3.2.20.1.3 Multicast Rx Frames (Offset = 8h)

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than 0xFFFFFFFFFFFF
- Had a length of 64 to rx_maxlen bytes inclusive
- Had no CRC error, alignment error or code error

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

15.3.2.20.1.4 Pause Rx Frames (Offset = Ch)

The total number of IEEE 802.3X pause frames received by the port (whether acted upon or not). Such a frame:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08 (hex) and the opcode 0x0001
- Was of length 64 to rx_maxlen bytes inclusive
- Had no CRC error, alignment error or code error
- Pause-frames had been enabled on the port (tx_flow_en = 1).

The port could have been in either half or full-duplex mode.

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

15.3.2.20.1.5 Rx CRC Errors (Offset = 10h)

The total number of frames received on the port that experienced a CRC error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was of length 64 to rx_maxlen bytes inclusive
- Had no code/align error,
- Had a CRC error

Overruns have no effect upon this statistic.

A CRC error is defined to be:

- A frame containing an even number of nibbles
- Failing the Frame Check Sequence test

15.3.2.20.1.6 Rx Align/Code Errors (Offset = 14h)

The total number of frames received on the port that experienced an alignment error or code error. Such a frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode

- Was of length 64 to rx_maxlen bytes inclusive
- Had either an alignment error or a code error

Overruns have no effect upon this statistic.

An alignment error is defined to be:

- A frame containing an odd number of nibbles
- Failing the Frame Check Sequence test if the final nibble is ignored

A code error is defined to be a frame which has been discarded because the port's MRXER pin driven with a one for at least one bit-time's duration at any point during the frame's reception.

Note: RFC 1757 etherStatsCRCAlignErrors Ref. 1.5 can be calculated by summing Rx Align/Code Errors and Rx CRC errors.

15.3.2.20.1.7 Oversize Rx Frames (Offset = 18h)

The total number of oversized frames received on the port. An oversized frame is defined to be:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than rx_maxlen in bytes
- Had no CRC error, alignment error or code error

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

15.3.2.20.1.8 Rx Jabbers (Offset = 1Ch)

The total number of jabber frames received on the port. A jabber frame:

- Was any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than rx_maxlen in bytes
- Had no CRC error, alignment error or code error

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

15.3.2.20.1.9 Undersize (Short) Rx Frames (Offset = 20h)

The total number of undersized frames received on the port. An undersized frame is defined to be:

- Was any data frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Was greater than rx_maxlen in bytes
- Had no CRC error, alignment error or code error

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

15.3.2.20.1.10 Rx Fragments (Offset = 24h)

The total number of frame fragments received on the port. A frame fragment is defined to be:

- Any data frame (address matching does not matter)
- Less than 64 bytes long
- Having a CRC error, an alignment error, or a code error
- Not the result of a collision caused by half duplex, collision based flow control

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

15.3.2.20.1.11 Rx Start of Frame Overruns (Offset = 84h)

The total number of frames received on the port that had a CPDMA start of frame (SOF) overrun or were dropped by due to FIFO resource limitations. SOF overrun frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than rx_maxlen bytes)
- The CPDMA had a start of frame overrun or the packet was dropped due to FIFO resource limitations

15.3.2.20.1.12 Rx Middle of Frame Overruns (Offset = 88h)

The total number of frames received on the port that had a CPDMA middle of frame (MOF) overrun. MOF overrun frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than rx_maxlen bytes)
- The CPDMA had a middle of frame overrun

15.3.2.20.1.13 Rx DMA Overruns (Offset = 8Ch)

The total number of frames received on the port that had either a DMA start of frame (SOF) overrun or a DMA MOF overrun. An Rx DMA overrun frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length (including less than 64 bytes and greater than rx_maxlen bytes)
- The CPGMAC_SL was unable to receive it because it did not have the DMA buffer resources to receive it (zero head descriptor pointer at the start or during the middle of the frame reception)

CRC errors, alignment errors and code errors have no effect upon this statistic.

15.3.2.20.1.14 Rx Octets (Offset = 30h)

The total number of bytes in all good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Of length 64 to rx_maxlen bytes inclusive
- Had no CRC error, alignment error or code error

See the Rx Align/Code Errors and Rx CRC errors statistic descriptions for definitions of alignment, code and CRC errors. Overruns have no effect upon this statistic.

15.3.2.20.1.15 Net Octets (Offset = 80h)

The total number of bytes of frame data received and transmitted on the port. Each frame counted:

- was any data or MAC control frame destined for any unicast, broadcast or multicast address (address match does not matter)
- Any length (including less than 64 bytes and greater than rx_maxlen bytes)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced, (i.e. multiple retries are counted each time)
- Every byte received if the port is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence was not counted to prevent double-counting)

Error conditions such as alignment errors, CRC errors, code errors, overruns and underruns do not affect the recording of bytes by this statistic.

The objective of this statistic is to give a reasonable indication of ethernet utilization

15.3.2.20.2 Tx-only Statistics Descriptions

The maximum and minimum transmit frame size is software controllable.

15.3.2.20.2.1 Good Tx Frames (Offset = 34h)

The total number of good frames received on the port. A good frame is defined to be:

- Any data or MAC control frame which matched a unicast, broadcast or multicast address, or matched due to promiscuous mode
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

15.3.2.20.2.2 Broadcast Tx Frames (Offset = 38h)

The total number of good broadcast frames received on the port. A good broadcast frame is defined to be:

- Any data or MAC control frame which was destined for only address 0xFFFFFFFFFFFF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

15.3.2.20.2.3 Multicast Tx Frames (Offset = 3Ch)

The total number of good multicast frames received on the port. A good multicast frame is defined to be:

- Any data or MAC control frame which was destined for any multicast address other than 0xFFFFFFFFFFFF
- Any length
- Had no late or excessive collisions, no carrier loss and no underrun

15.3.2.20.2.4 Pause Tx Frames (Offset = 40h)

This statistic indicates the number of IEEE 802.3X pause frames transmitted by the port.

Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect upon the statistic. Pause frames sent by software will not be included in this count.

Since pause frames are only transmitted in full duplex carrier loss and collisions have no effect upon this statistic.

Transmitted pause frames are always 64 byte multicast frames so will appear in the Tx Multicast Frames and 64octet Frames statistics.

15.3.2.20.2.5 Collisions (Offset = 48h)

This statistic records the total number of times that the port experienced a collision. Collisions occur under two circumstances.

1. When a transmit data or MAC control frame:
   - Was destined for any unicast, broadcast or multicast address
   - Was any size
   - Had no carrier loss and no underrun
   - Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic will increment on each occasion if a frame experiences multiple collisions (and increments on late collisions)

   CRC errors have no effect upon this statistic.
2. When the port is in half-duplex mode, flow control is active, and a frame reception begins.

15.3.2.20.2.6 Single Collision Tx Frames (Offset = 4Ch)

The total number of frames transmitted on the port that experienced exactly one collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect upon this statistic.

15.3.2.20.2.7 Multiple Collision Tx Frames (Offset = 50h)

The total number of frames transmitted on the port that experienced multiple collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect upon this statistic.

15.3.2.20.2.8 Excessive Collisions (Offset = 54h)

The total number of frames for which transmission was abandoned due to excessive collisions. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect upon this statistic.

15.3.2.20.2.9 Late Collisions (Offset = 58h)

The total number of frames on the port for which transmission was abandoned because they experienced a late collision. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions which had previously required the transmission to be re-attempted. The Late Collisions statistic dominates over the single, multiple and excessive Collisions statistics - if a late collision occurs the frame will not be counted in any of these other three statistics.

CRC errors have no effect upon this statistic.

15.3.2.20.2.10 Tx Underrun (Offset = 5Ch)

There should be no transmitted frames that experience underrun.

15.3.2.20.2.11 Deferred Tx Frames (Offset = 44h)

The total number of frames transmitted on the port that first experienced deferment. Such a frame:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted

- Found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect upon this statistic.

15.3.2.20.2.12 Carrier Sense Errors (Offset = 60h)

The total number of frames received on the port that had a CPDMA middle of frame (MOF) overrun. MOF overrun frame is defined to be:

- Was any data or MAC control frame destined for any unicast, broadcast or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted). This is a transmit only statistic. Carrier Sense is a don't care for received frames. Transmit frames with carrier sense errors are sent until completion and are not aborted.

CRC errors have no effect upon this statistic.

15.3.2.20.2.13 Tx Octets (Offset = 64h)

The total number of bytes in all good frames transmitted on the port. A good frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Was any size
- Had no late or excessive collisions, no carrier loss and no underrun.

15.3.2.20.3 Rx- and Tx-Shared Statistics Descriptions

15.3.2.20.3.1 Rx + Tx 64 Octet Frames (Offset = 68h)

The total number of 64-byte frames received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was exactly 64 bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame will be recorded in this statistic).

CRC errors, code/align errors and overruns do not affect the recording of frames in this statistic.

15.3.2.20.3.2 Rx + Tx 65–127 Octet Frames (Offset = 6Ch)

The total number of frames of size 65 to 127 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 65 to 127 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

15.3.2.20.3.3 Rx + Tx 128–255 Octet Frames (Offset = 70h)

The total number of frames of size 128 to 255 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 128 to 255 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

15.3.2.20.3.4 Rx + Tx 256–511 Octet Frames (Offset = 74h)

The total number of frames of size 256 to 511 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 256 to 511 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

15.3.2.20.3.5 Rx + Tx 512–1023 Octet Frames (Offset = 78h)

The total number of frames of size 512 to 1023 bytes received and transmitted on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 512 to 1023 bytes long

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

15.3.2.20.3.6 Rx + Tx 1024_Up Octet Frames (Offset = 7Ch)

The total number of frames of size 1024 to rx_maxlen bytes for receive or 1024 up for transmit on the port. Such a frame is defined to be:

- Any data or MAC control frame which was destined for any unicast, broadcast or multicast address
- Did not experience late collisions, excessive collisions, or carrier sense error
- Was 1024 to rx_maxlen bytes long on receive, or any size on transmit

CRC errors, code/align errors, underruns and overruns do not affect the recording of frames in this statistic.

Table 15-18. Rx Statistics Summary

Rx Statistic	Frame/ Oct	Rx/ Rx+Tx	Frame Type					Frame Size (bytes)								Event				
			MAC control		Data															
			Pause frame	Non-pause	Multi-cast	Broad-cast	Uni-cast	<64	64	65-127	128-255	256-511	512-1023	1024-rx_maxlen	>rx_maxlen	Flow Coll.	CRC Error	Align/ Code	Over-run	Addr. Disc.
Good Rx Frames	F	Rx	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Broadcast Rx Frames	F	Rx	(%|	%|	n	y)	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Multicast Rx Frames	F	Rx	(%|	%|	y)	n	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Pause Rx Frames	F	Rx	y	n	n	n	n	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	-
Rx CRC Errors	F	Rx	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	y	n	-	n
Rx Align/Code Errors	F	Rx	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	-	y	-	n
Oversized Rx Frames	F	Rx	(y|	y|	y|	y|	y)	n	n	n	n	n	n	n	y	-	n	n	-	n
Rx Jabbers	F	Rx	(y|	y|	y|	y|	y)	n	n	n	n	n	n	n	y	-	(y|	y)	-	n
Undersized Rx Frames	F	Rx	n	n	(y|	y|	y)	y	n	n	n	n	n	n	n	-	n	n	-	n
Rx Fragments	F	Rx	n	n	(y|	y|	y)	y^^	n	n	n	n	n	n	n	-	(y|	y)	-	-
Rx Overruns	F	Rx	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y|	y)	-	-	-	y	n
64octet Frames	F	Rx+Tx	(y|	y|	y|	y|	y)	n	y	n	n	n	n	n	n	-	-	-	-	n
65-127octet Frames	F	Rx+Tx	(y|	y|	y|	y|	y)	n	n	y	n	n	n	n	n	-	-	-	-	n
128-255octet Frames	F	Rx+Tx	(y|	y|	y|	y|	y)	n	n		y	n	n	n	n	-	-	-	-	n
256-511octet Frames	F	Rx+Tx	(y|	y|	y|	y|	y)	n	n	n	n	y	n	n	n	-	-	-	-	n
512-1023octet Frames	F	Rx+Tx	(y|	y|	y|	y|	y)	n	n	n	n	n	y	n	n	-	-	-	-	n
1024-UPoctet Frames	F	Rx+Tx	(y|	y|	y|	y|	y)	n	n	n	n	n	n	y	n	-	-	-	-	n
Rx Octets	O	Rx	(y|	y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	n	-	n	n	-	n
Net Octets	O	Rx+Tx	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y|	y|	y)	-	-	-	-

Notes for the Rx Statistics Summary:

1. “AND” is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning “OR” is indicated. Parentheses are significant.
2. “-“ indicates conditions which are ignored in the formations of the statistic.
3. Statistics marked “Rx+Tx” are formed by summing the Rx and Tx statistics, each of which is formed independently.
4. The non-pause column refers to all MAC control frames (i.e. frames with length/type=88.08) with opcodes other than 0x0001. The pauseframe column refers to MAC frames with the opcode=0x0001.
5. The multicast, broadcast and unicast columns in the table refer to non-MACCTRL/non-pause frames (i.e. data frames).
6. “%” If either a MAC control frame or pause frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
7. “y^” Frame fragments are not counted if less than 8 bytes.
8. flow coll. are half-duplex collisions forced by the MAC to achieve flow-control. A collision will be forced during the first 8 bytes so should not show in frame fragments. Some of the ‘-‘s in this column might in reality be ‘n’s.
9. The rx_overruns stat show above is for rx_mof_overruns and rx_sof_overruns added together.

Table 15-19. Tx Statistics Summary

Tx Statistic	Frame/ Oct	Tx/ Rx+ Tx	Frame Type					Frame Size (bytes)							Event									
			MAC control		Data											Collision Type								
			Pause (MAC)	Any (CPU)	Multi-cast	Broad-cast	Uni-cast	64	65-127	128-255	256-511	512-1023	1024-1535	> 1535	CRC Error	Flow	1	2-15	16	Late	No Carrier	Queued	Deferred	Under-run
Good Tx Frames	F	Tx	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Broadcast Tx Frames	F	Tx	n	(%|	n	y)	n	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Multicast Tx Frames	F	Tx	(y|	%|	y)	n	n	y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Pause Tx Frames	F	Tx	y	n	n	n	n	y	n	n	n	n	n	n	-	-	-	-	-	-	-	-	-	-
Collisions	F	Tx	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	(+	+	+	+	+)	n	-	-	-
Single Collision Tx Frames	F	Tx	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	y	n	n	n	n	-	-	-
Multiple Collision Tx Frames	F	Tx	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	n	y	n	n	n	-	-	-
Excessive Collisions	F	Tx	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	n	n	y	n	n	-	-	-
Late Collisions	F	Tx	n	(y|	y|	y|	y)	n	(y|	y|	y|	y|	y|	y)	-	-	-	-	-	y	-	-	-	-
Deferred Tx Frames	F	Tx	n	(y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	n	n	n	n	n	-	y	n
Carrier Sense Errors	F	Tx	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	-	-	y	-	-	-
64octet Frames	F	Rx+ Tx	(y|	y|	y|	y|	y)	y	n	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
65-127octet Frames	F	Rx+ Tx	(y|	y|	y|	y|	y)	n	y	n	n	n	n	n	-	-	-	-	n	n	n	-	-	-
128-255octet Frames	F	Rx+ Tx	(y|	y|	y|	y|	y)	n	n	y	n	n	n	n	-	-	-	-	n	n	n	-	-	-
256-511octet Frames	F	Rx+ Tx	(y|	y|	y|	y|	y)	n	n	n	y	n	n	n	-	-	-	-	n	n	n	-	-	-
512-1023octet Frames	F	Rx+ Tx	(y|	y|	y|	y|	y)	n	n	n	n	y	n	n	-	-	-	-	n	n	n	-	-	-
1024-UPoctet Frames	F	Rx+ Tx	(y|	y|	y|	y|	y)	n	n	n	n	n	y	y	-	-	-	-	n	n	n	-	-	-
Tx Octets	O	Tx	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	-	-	n	n	n	-	-	n
Net Octets	O	Rx+ Tx	(y|	y|	y|	y|	y)	(y|	y|	y|	y|	y|	y|	y)	-	-	$	$	$	$	$	-	-	-

Notes for the Tx Statistics Summary:

1. "AND" is assumed horizontally across the table between all conditions which form the statistic (marked y or n) except where (y|y), meaning “OR” is indicated. Parentheses are significant.
2. “-“ indicates conditions which are ignored in the formations of the statistic.
3. Statistics marked “Rx+Tx” are formed by summing the Rx and Tx statistics, each of which is formed independently.
4. Pause (MAC) frames are issued in the MAC as perfect (no CRC error) 64 byte frames in full duplex only, so they cannot collide.
5. “%” If a CPU sourced MAC control frame has a multicast or broadcast destination address then the appropriate statistics will be updated.
6. “+” indicates collisions which are “summed” (i.e. every collision is counted in the Collisions statistic). Jam sequences used for halfduplex flow control are also counted.
7. “$” Every byte written on the wire during each retry attempt is also counted in addition to frames which experience no collisions or carrier loss.
8. The flow collision type is for half-duplex collisions forced by the MAC to achieve flow control. Some of the ‘-‘s in this column might in reality be ‘n’s. To prevent double-counting, Net Octets are unaffected by the jam sequence – the ‘received’ bytes, however, are counted. (See Table 15-18.)
9. When the transmit Tx FIFO is drained due to the MAC being disabled or link being lost, then the frames being purged will not appear in the Tx statistics.

15.3.3 Ethernet Mac Sliver (CPGMAC_SL)

The CPGMAC_SL peripheral shall be compliant to the IEEE Std 802.3 Specification. Half duplex mode is supported in 10/100 Mbps mode, but not in 1000 Mbps (gigabit) mode.

Features:

- Synchronous 10/100/1000 Mbit operation.
- G/MII Interface.
- Hardware Error handling including CRC.
- Full Duplex Gigabit operation (half duplex gigabit is not supported).
- EtherStats and 802.3Stats RMON statistics gathering support for external statistics collection module.
- Transmit CRC generation selectable on a per channel basis.
- Emulation Support.
- VLAN Aware Mode Support.
- Hardware flow control.
- Programmable Inter Packet Gap (IPG)

15.3.3.1 GMII/MII Media Independent Interface

The following sections cover operation of the Media Independent Interface in 10/100/1000 Mbps modes. An IEEE 802.3 compliant Ethernet MAC controls the interface.

15.3.3.1.1 Data Reception

15.3.3.1.1.1 Receive Control

Data received from the PHY is interpreted and output. Interpretation involves detection and removal of the preamble and start of frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation.

15.3.3.1.1.2 Receive Inter-Frame Interval

The 802.3 required inter-packet gap (IPG) is 24 GMII clocks (96 bit times) for 10/100 Mbit modes, and 12 GMII clocks (96 bit times) for 1000 Mbit mode. However, the MAC can tolerate a reduced IPG (2 GMII clocks in 10/100 mode and 5 GMII clocks in 1000 mode) with a correct preamble and start frame delimiter.

This interval between frames must comprise (in the following order):

- An Inter-Packet Gap (IPG).
- A seven octet preamble (all octets 0x55).
- A one octet start frame delimiter (0x5D).

15.3.3.1.2 Data Transmission

The Gigabit Ethernet Mac Sliver (GMII) passes data to the PHY when enabled. Data is synchronized to the transmit clock rate. The smallest frame that can be sent is two bytes of data with four bytes of CRC (6 byte frame).

15.3.3.1.2.1 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted) the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full duplex mode the carrier sense (CRS) and collision sensing modes are disabled.

15.3.3.1.2.2 CRC Insertion

The MAC generates and appends a 32-bit Ethernet CRC onto the transmitted data if the transmit packet header **pass_crc** bit is zero. For the CPMAC_SL generated CRC case, a CRC at the end of the input packet data is not allowed.

If the header word **pass_crc** bit is set, then the last four bytes of the TX data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the packet byte count value. The MAC performs no error checking on the outgoing CRC when the **pass_crc** bit is set.

15.3.3.1.2.3 TXER

The GMII_TXER signal is not used. If an underflow condition occurs on a transmitted frame, the frame CRC will be inverted to indicate the error to the network. Underflow is a hardware error.

15.3.3.1.2.4 Adaptive Performance Optimization (APO)

The Ethernet MAC port incorporates Adaptive Performance Optimization (APO) logic that may be enabled by setting the **tx_pace** bit in the **MACCTRL** register. Transmission pacing to enhance performance is enabled when set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions) thereby increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision or excessive collision) the pacing counter is decremented by one, down to zero.

With pacing enabled, a new frame is permitted to immediately (after one IPG) attempt transmission only if the pacing counter is zero. If the pacing counter is non zero, the frame is delayed by the pacing delay, a delay of approximately four inter-packet gap delays. APO only affects the IPG preceding the first attempt at transmitting a frame. It does not affect the back-off algorithm for retransmitted frames.

15.3.3.1.2.5 Inter-Packet-Gap Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision, and **GMII_CRS** is de-asserted within approximately 48 bit times of **GMII_TXEN** being de-asserted, then 96 bit times is measured from **GMII_TXEN**. If the frame suffered a collision, or if **GMII_CRS** is not de-asserted until more than approximately 48 bit times after **GMII_TXEN** s de-asserted, then 96 bit times (approximately, but not less) is measured from **GMII_CRS**.

The transmit IPG can be shortened by eight bit times when enabled and triggered. The **tx_short_gap_en** bit in the **MACCTRL** register enables the **TX_SHORT_GAP** input to determine whether the transmit IPG is shorted by eight bit times.

15.3.3.1.2.6 Back Off

The Gigabit Ethernet Mac Sliver (GMII) implements the 802.3 binary exponential back-off algorithm.

15.3.3.1.2.7 Programmable Transmit Inter-Packet Gap

The transmit inter-packet gap (IPG) is programmable through the **Tx_Gap** register. The default value is decimal 12. The transmit IPG may be increased to the maximum value of 0x1ff. Increasing the IPG is not compatible with transmit pacing. The short gap feature will override the increased gap value, so the short gap feature may not be compatible with an increased IPG.

15.3.3.1.2.8 Speed, Duplex, and Pause Frame Support Negotiation

The CPMAC_SL can operate in half duplex or full duplex in 10/100 Mbit modes, and can operate in full duplex only in 1000 Mbit mode. Pause frame support is included in 10/100/1000 Mbit modes as configured by the host.

15.3.3.2 Frame Classification

Received frames are proper (good) frames if they are between 64 and **rx_maxlen** in length (inclusive) and contain no errors (code/align/CRC).

Received frames are long frames if their frame count exceeds the value in the **rx_maxlen** register. The **rx_maxlen** register reset (default) value is 1518 (dec). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames if their frame count is less than 64 bytes. Short frames that contain no errors are undersized frames. Short frames with CRC, code, or alignment errors are fragment frames.

A received long packet will always contain **rx_maxlen** number of bytes transferred to memory (if **rx_cef_en** = 1). An example with **rx_maxlen** = 1518 is below:

- If the frame length is 1518, then the packet is not a long packet and there will be 1518 bytes transferred to memory.
- If the frame length is 1519, there will be 1518 bytes transferred to memory. The last three bytes will be the first three CRC bytes.
- If the frame length is 1520, there will be 1518 bytes transferred to memory. The last two bytes will be the first two CRC bytes.
- If the frame length is 1521, there will be 1518 bytes transferred to memory. The last byte will be the first CRC byte.

If the frame length is 1522, there will be 1518 bytes transferred to memory. The last byte will be the last data byte.

15.3.4 Command IDLE

The cmd_idle bit in the MACCTRL register allows CPGMAC_SL operation to be suspended. When the idle state is commanded, the CPGMAC_SL will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. Received frames that are detected after the suspend state is entered are ignored. Commanded idle is similar in operation to emulation control and clock stop.

15.3.5 RMII Interface

The CPRMII peripheral shall be compliant to the RMII specification document.

Features:

- Source Synchronous 10/100 Mbit operation.
- Full and Half Duplex support.

15.3.5.1 RMII Receive (RX)

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (CPGMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted RMII_RXER on any di-bit in the received packet will cause an MII_RXER assertion to the CPGMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted RMII_RXER during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned RMII_CRS_DV toggle will issue an MII_RXER during the packet to the CPGMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5d is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMII_CRS_DV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

15.3.5.2 RMII Transmit (TX)

The CPRMII transmit (TX) interface converts the 3PSW MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The 3PSW does not source the transmit error (MII TXERR) signal. Any transmit frame from the CPGMAC with an error (ie. underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be deasserted at all times and is not an input into the CPRMII module.Zeroes are output on RMII_TXD[1:0] for each clock that RMII_TXEN is deasserted.

15.3.6 RGMII Interface

The CPRGMII peripheral shall be compliant to the RGMII specification document.

Features:

- Supports 1000/100/10 Mbps Speed.
- MII mode is not supported.

If RGMII is used, and a 10Mbit operation is desired, in-band mode must be used and an ethernet PHY that supports in-band status signaling must be selected.

15.3.6.1 RGMII Receive (RX)

The CPRGMII receive (RX) interface converts the source synchronous DDR input data from the external RGMII PHY into the required G/MII (CPGMAC) signals.

15.3.6.2 In-Band Mode of Operation

The CPRGMII is operating in the in-band mode of operation when the **RGMII_RX_INBAND** input is asserted.RGMII_RX_INPUT is asserted by configuring the ext_en bit to 1 of the MACCTRL register. The link status, duplexity, and speed are determined from the RGMII input data stream as defined in the RGMII specification. The link speed is indicated as shown in the following table:

RGMII_SPEED(1:0)	Link Speed
00	10 Mbs mode
01	100 Mbs mode
10	1000 Mbs mode
11	reserved

15.3.6.3 Forced Mode of Operation

The CPRGMII is operating in the forced mode of operation when the **RGMII_RX_INBAND** input is deasserted by setting MACCTRL.EXT_EN to 0. In the forced mode of operation, the in-band data is ignored if present. In this mode, the contents of RGMII_CTL are meaningless. Link status, duplexity, and speed status should be determined from the external ethernet PHY via MDIO transactions.

15.3.6.4 RGMII Transmit (TX)

The CPRGMII transmit (TX) interface converts the CPGMAC G/MII input data into the DDR RGMII format. The DDR data is then output to the external PHY.

The CPGMAC does not source the transmit error (MTXERR) signal. Any transmit frame from the CPGMAC with an error (that is, underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be deasserted at all times and is not an input into the CPRGMII module.

The RGMII0/1_ID_MODE bit value in the GMII_SEL register should only be set to 1 for 'no internal delay'. The device does not support internal delay mode for RGMII.

15.3.7 Common Platform Time Sync (CPTS)

The CPTS module is used to facilitate host control of time sync operations. It enables compliance with the IEEE 1588-2008(v2) standard for a precision clock synchronization protocol.

15.3.7.1 Architecture

Figure 15-10. CPTS Block Diagram

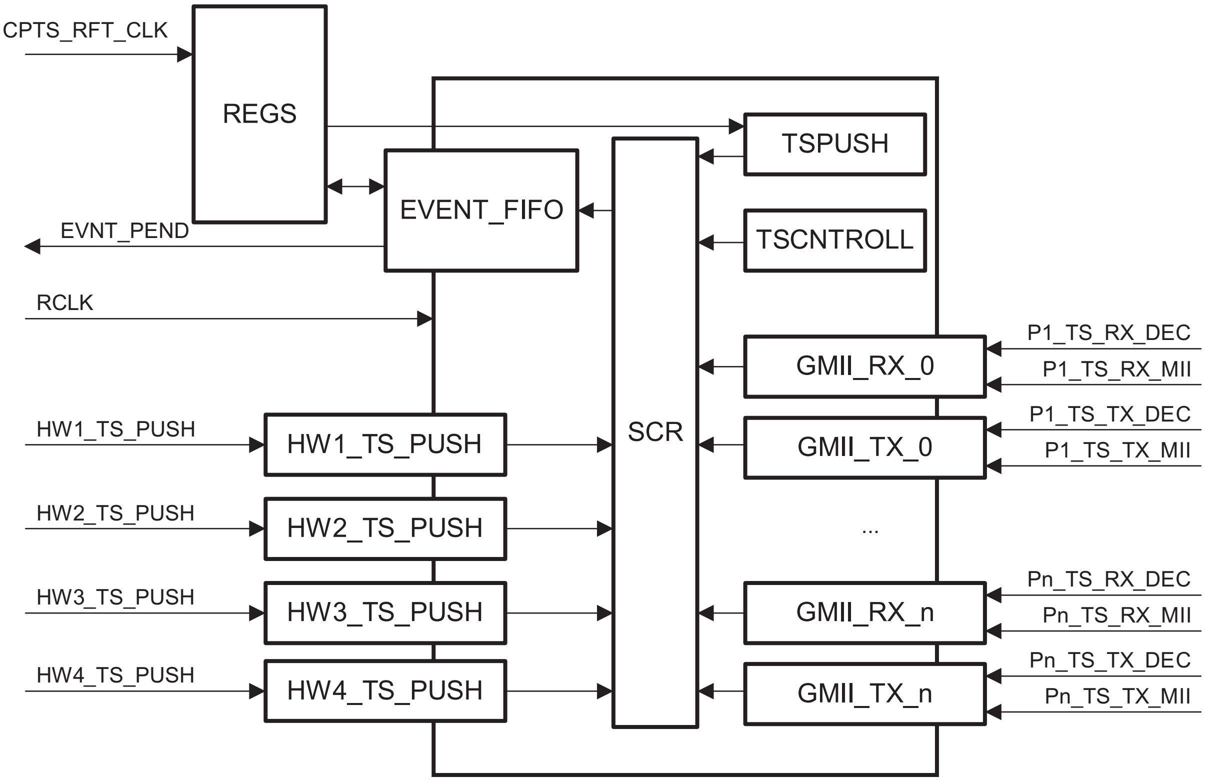

Figure 15-10 shows the architecture of the CPTS module inside the 3PSW Ethernet Subsystem. Time stamp values for every packet transmitted or received on either port of the 3PSW are recorded. At the same time, each packet is decoded to determine if it is a valid time sync event. If so, an event is loaded into the Event FIFO for processing containing the recorded time stamp value when the packet was transmitted or received.

In addition, both hardware (HWx_TS_PUSH) and software (TS_PUSH) can be used to read the current time stamp value though the Event FIFO

The reference clock used for the time stamp (RCLK) is sourced from one of the two sources, as shown in Figure 15-10. The source can be selected by configuring the CM_CPTS_RFT_CLKSEL register in the Control Module. For more details, see Chapter 7, *Control Module*.

15.3.7.2 Time Sync Overview

The CPTS module is used to facilitate host control of time sync operations. The CPTS collects time sync events and then presents them to the host for processing. There are five types of time sync events (ethernet receive event, ethernet transmit event, time stamp push event, time stamp rollover event, and time stamp half-rollover event). Each ethernet port can cause transmit and receive events. The time stamp push is initiated by software.

15.3.7.2.1 Time Sync Initialization

The CPTS module should be configured as shown:

- Complete the reset sequence (VBUSP_RST_N) to reset the module.
- Write the rftclk_sel[4:0] value in the RFTCLK_Sel register with the desired reference clock multiplexor value. This value is allowed to be written only when the cpts_en bit is cleared to zero.
- Write a one to the cpts_en bit in the TS_Ctrl register. The RCLK domain is in reset while this bit is low.
- Enable the interrupt by writing a one to the ts_pend_en bit in the TS_Int_En register (if using interrupts and not polling).

15.3.7.2.2 Time Stamp Value

The time stamp value is a 32-bit value that increments on each RCLK rising edge when CPTS_EN is set to one. When CPTS_EN is cleared to zero the time stamp value is reset to zero. If more than 32-bits of time stamp are required by the application, the host software must maintain the necessary number of upper bits. The upper time stamp value should be incremented by the host when the rollover event is detected.

For test purposes, the time stamp can be written via the time stamp load function (CPTS_LOAD_VAL and CPTS_LOAD_EN registers).

15.3.7.2.3 Event FIFO

All time sync events are pushed onto the Event FIFO. There are 16 locations in the event FIFO with no overrun indication supported. Software must service the event FIFO in a timely manner to prevent FIFO overrun.

15.3.7.2.4 Time Sync Events

Time Sync events are 64-bit values that are pushed onto the event FIFO and read in two 32-bit reads. CPTS_EVT_LOW and CPTS_EVT_HIGH are defined in and , respectively.

There are six types of sync events

- Time stamp push event
- Hardware time stamp push event
- Time stamp counter rollover event
- Time stamp counter half-rollover event
- Ethernet receive event
- Ethernet transmit event

15.3.7.2.4.1 Time Stamp Push Event

Software can obtain the current time stamp value (at the time of the write) by initiating a time stamp push event. The push event is initiated by setting the TS_PUSH bit of the CPTS_TS_PUSH register. The time stamp value is returned in the event, along with a time stamp push event code. Software should not push a second time stamp event on to the FIFO until the first time stamp value has been read from the event FIFO.

15.3.7.2.4.2 Time Stamp Counter Rollover Event

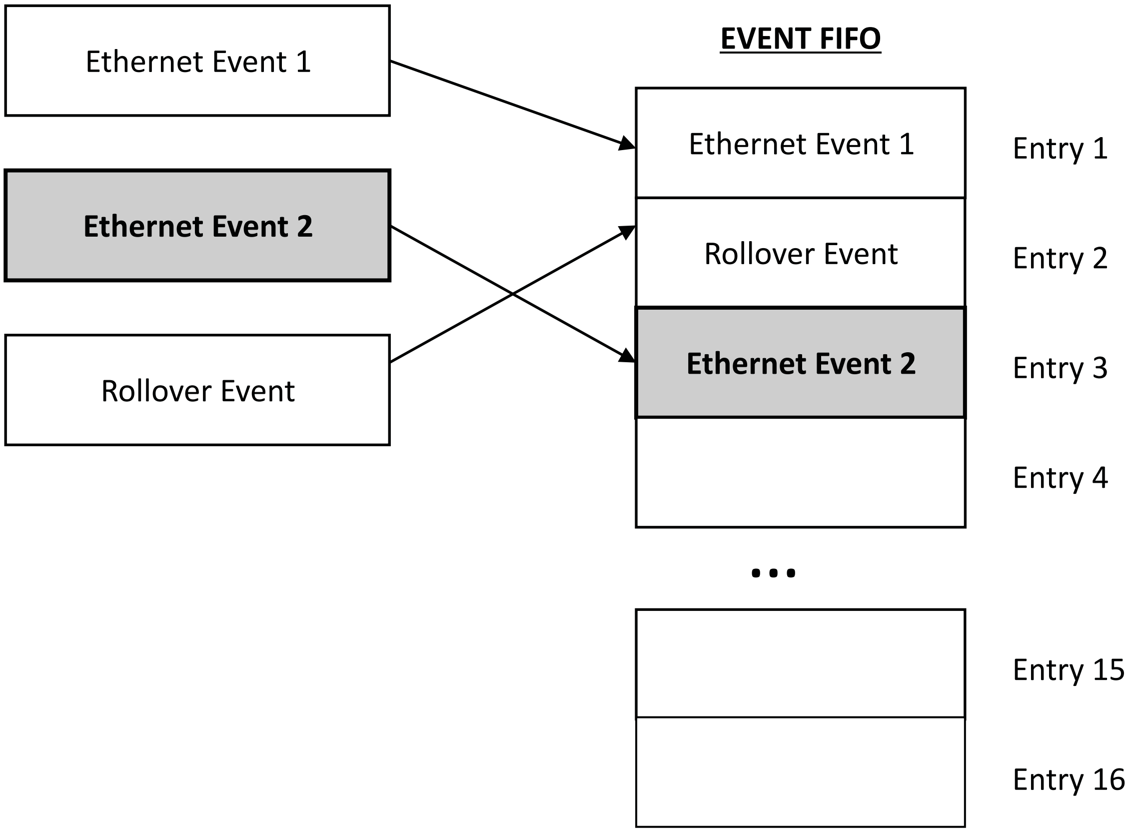
The CPTS module contains a 32-bit time stamp value. The counter upper bits are maintained by host software. The rollover event indicates to software that the time stamp counter has rolled over from 0xFFFF_FFFF to 0x0000_0000, and the software maintained upper count value should be incremented.

15.3.7.2.4.3 Time Stamp Counter Half-Rollover Event

The CPTS includes a time stamp counter half-rollover event. The half-rollover event indicates to software that the time stamp value has incremented from 0x7FFF_FFFF to 0x8000_0000. The half-rollover event is included to enable software to correct a misaligned event condition.The half-rollover event is included to enable software to determine the correct time for each event that contains a valid time stamp value – such as an Ethernet event. If an Ethernet event occurs around a counter rollover (full rollover), the rollover event could possibly be loaded into the event FIFO before the Ethernet event, even though the Ethernet event time was actually taken before the rollover. Figure 3 below shows a misalignment condition.

This misaligned event condition arises because an ethernet event time stamp occurs at the beginning of a packet and time passes before the packet is determined to be a valid synchronization packet. The misaligned event condition occurs if the rollover occurs in the middle, after the packet time stamp has been taken, but before the packet has been determined to be a valid time sync packet.

Figure 15-11. Event FIFO Misalignment Condition



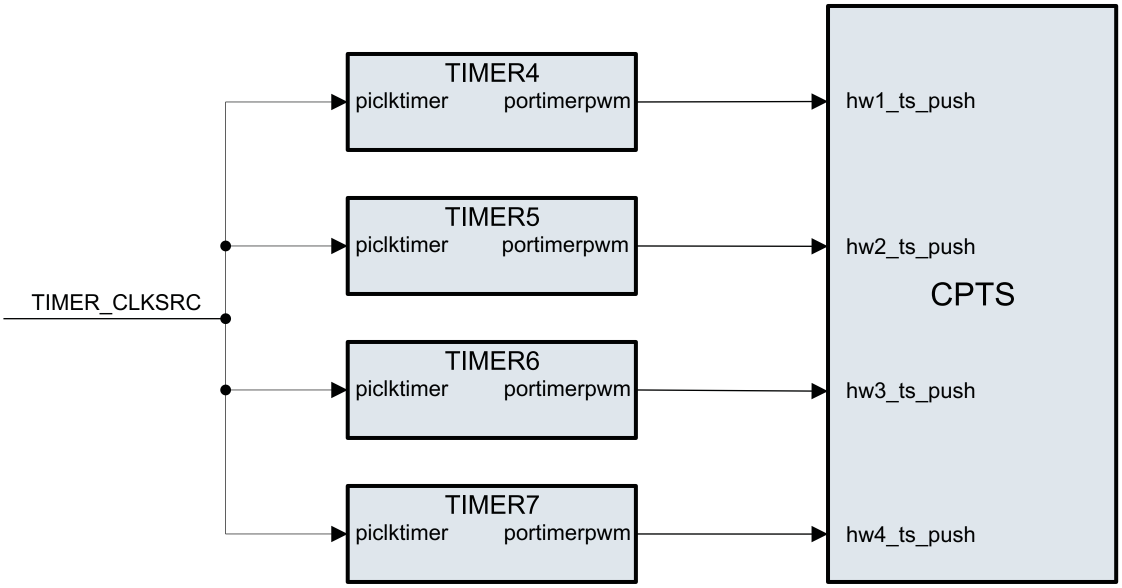
Host software must detect and correct for misaligned event conditions. For every event after a rollover and before a half-rollover, software must examine the time stamp most significant bit. If bit 31 of the time stamp value is low (0x0000_0000 through 0x7FFF_FFFF), then the event time stamp was taken after the rollover and no correction is required.

If the value is high (0x8000_0000 through 0xFFFF_FFFF), the time stamp value was taken before the rollover and a misalignment is detected. The misaligned case indicates to software that it must subtract one from the upper count value stored in software to calculate the correct time for the misaligned event.The misaligned event occurs only on the rollover boundary and not on the half-rollover boundary. Software only needs to check for misalignment from a rollover event to a half-rollover event.

15.3.7.2.4.4 Hardware Time Stamp Push Event

There are four hardware time stamp inputs (HW1/4_TS_PUSH) that can cause hardware time stamp push events to be loaded into the Event FIFO. Each hardware time stamp input is internally connected to the PORTIMERPWM output of each timer as shown in Figure 4.

Figure 15-12. HW1/4_TSP_PUSH Connection



The event is loaded into the event FIFO on the rising edge of the timer, and the PORT_NUMBER field in the EVT_HIGH register indicates the hardware time stamp input that caused the event.

Each hardware time stamp input must be asserted for at least 10 periods of the selected RCLK clock. Each input can be enabled or disabled by setting the respective bits in the ***CONTROL*** register.

Hardware time stamps are intended to be an extremely low frequency signals, such that the event FIFO does not overrun. Software must keep up with the event FIFO and ensure that there is no overrun, or events will be lost.

15.3.7.2.4.5 Ethernet Port Events

15.3.7.2.4.5.1 Ethernet Port Receive Event

Each ethernet port can generate a receive ethernet event. Receive ethernet events are generated for valid received time sync packets. There are two CPTS interfaces for each ethernet receive port. The first is the Px_TS_RX_MII interface and the second is the Px_TS_RX_DEC interface. Information from these interfaces is used to generates an ethernet receive event for each ethernet time sync packet received on the associated port.

The Px_TS_RX_MII interface issues a record signal (pX_ts_rx_mii_rec) along with a handle (pX_ts_rx_mii_hndl) for each packet (every packet) that is received on the associated ethernet port. The record signal is a single clock pulse indicating that a receive packet has been detected at the associated port MII interface. The handle value is incremented with each packet and rolls over to zero after 15.

There are 16 possible handle values so there can be a maximum of 16 packets “in flight” from the TS_RX_MII to the TS_RX_DEC block at any given time. A handle value is reused (not incremented) for any received packet that is shorter than about 31 octets (including preamble). Handle reuse on short packets prevents any possible overrun condition (more than 16 “in flight” packets) if multiple fragments are consecutively received.

Valid receive ethernet time sync events are signaled to the CPTS via the Px_TS_RX_DEC interface. When the pX_ts_rx_dec_evnt is asserted, a valid event is detected and will be loaded into the event FIFO. Only valid receive time sync packets are indicated on the Px_TS_RX_DEC interface. The pX_ts_rx_dec_hndl, pX_ts_rx_dec_msg_type, and pX_ts_rx_dec_seq_id signals are registered on an asserted pX_ts_rx_dec_evnt. When a Tx_TS_RX_DEC event is asserted, the handle value is used to retrieve the time stamp that was loaded with the same handle value from the Px_TS_RX_MII interface.

15.3.7.2.4.5.2 Ethernet Port Transmit Event

Each ethernet port can generate a transmit ethernet event. Transmit ethernet events are generated for valid transmitted time sync packets. There are two CPTS interfaces for each ethernet transmit port. The first is the Px_TS_TX_DEC interface and the second is the Px_TS_TX_MII interface. Information from these interfaces is used to generates an ethernet transmit event for each ethernet time sync packet transmitted on the associated port.

Valid ethernet transmit time sync events are signaled to the CPTS via the Px_TS_TX_DEC interface. When the pX_ts_tx_dec_evnt signal is asserted, a valid time sync event has been detected and will be loaded into the event FIFO. Only valid transmit time sync packets are indicated on the Px_TS_RX_DEC interface. The pX_ts_tx_dec_hndl, pX_ts_tx_dec_msg_type, pX_ts_tx_dec_seq_id signals are registered on an asserted pX_ts_tx_dec_evnt.

The time stamp for the event will be generated and signaled from the Px_TS_TX_MII interface when the packet is actually transmitted. The event will be loaded into the event FIFO when the time stamp is recorded as controlled by the Px_TS_TX_MII interface. The handle value is incremented with each time sync event packet and rolls over to zero after 7. There are 8 possible handle values so there can be a maximum of 8 time sync event packets “in flight” from the TS_TX_DEC to the TS_TX_MII block at any given time. The handle value increments only on time sync event packets.

The Px_TS_TX_MII interface issues a single clock record signal (pX_ts_tx_mii_rec) at the beginning of each transmitted packet. If the packet is a time sync event packet then a single clock event signal (pX_ts_tx_mii_evnt) along with a handle (pX_ts_rx_mii_hndl) will be issued before the next record signal for the next transmitted packet. The event signal will not be issued for packets that were not indicated as valid time sync event packets on the Px_TS_TX_DEC interface. If consecutive record indications occur without an interleaving event indication, then the packet associated with the first record was not a time sync event packet. The record signal is a single clock pulse indicating that a transmit packet egress has been detected at the associated port MII interface.

Table 15-20. Values of messageType field

Reserved	E-F

15.3.7.3 Interrupt Handling

When an event is push onto the Event FIFO, an interrupt can be generated to indicate to software that a time sync event occurred. The following steps should be taken to process time sync events using interrupts:

- Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_INT_EN register.
- Upon interrupt, read the CPTS_EVT_LOW and CPTS_EVT_HIGH register values.
- Set the EVT_POP field (bit zero) of the CPTS_EVT_POP register to pop the previously read value off of the event FIFO.
- Process the interrupt as required by the application software

Software has the option of processing more than a single event from the event FIFO in the interrupt service routine in the following way:

1. Enable the TS_PEND interrupt by setting the TS_PEND_EN bit of the CPTS_INT_EN register.
2. Upon interrupt enter the CPTS service routine.
3. Read the CPTS_EVT_LOW and CPTS_EVT_HIGH register values.
4. Set the EVT_POP bit of the CPTS_EVT_POP register to pop the previously read value off of the event FIFO.
5. Wait for an amount of time greater than eight CPTS_RFT_CLK periods
6. Read the ts_pend_raw bit in the CPTS_INTSTAT_RAW register to determine if another valid event is in the event FIFO. If it is asserted then goto step 3. Otherwise goto step 7.
7. Process the interrupt(s) as required by the application software

Software also has the option of disabling the interrupt and polling the ts_pend_raw bit of the CPTS_INTSTAT_RAW register to determine if a valid event is on the event FIFO.

15.3.8 MDIO

The MII Management I/F module implements the 802.3 serial management interface to interrogate and control two Ethernet PHYs simultaneously using a shared two-wire bus. Two user access registers to control and monitor up to two PHYs simultaneously.

15.3.8.1 MII Management Interface Frame Formats

The following tables show the read and write format of the 32-bit MII Management interface frames, respectively.

Table 15-21. MDIO Read Frame Format

Preamble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
0xFFFF FFFF	01	10	AAAAA	RRRRR	Z0	DDDD.DDDD. DDDD.DDDD

Table 15-22. MDIO Write Frame Format

Preamble	Start Delimiter	Operation Code	PHY Address	Register Address	Turnaround	Data
0xFFFF FFFF	01	01	AAAAA	RRRRR	10	DDDD.DDDD. DDDD.DDDD

The default or idle state of the two wire serial interface is a logic one. All tri-state drivers should be disabled and the PHY's pull-up resistor will pull the **MDIO_DATA** line to a logic one. Prior to initiating any other transaction, the station management entity shall send a preamble sequence of 32 contiguous logic one bits on the **MDIO_DATA** line with 32 corresponding cycles on **MDIO_CLK** to provide the PHY with a pattern that it can use to establish synchronization. A PHY shall observe a sequence of 32 contiguous logic one bits on **MDIO_DATA** with 32 corresponding **MDIO_CLK** cycles before it responds to any other transaction.

Preamble

The start of a frame is indicated by a preamble, which consists of a sequence of 32 contiguous bits all of which are a “1”. This sequence provides the PHY a pattern to use to establish synchronization.

Start Delimiter

The preamble is followed by the start delimiter which is indicated by a “01” pattern. The pattern assures transitions from the default logic one state to zero and back to one.

Operation Code

The operation code for a read is “10”, while the operation code for a write is a “01”.

PHY Address

The PHY address is 5 bits allowing 32 unique values. The first bit transmitted is the MSB of the PHY address.

Register Address

The Register address is 5 bits allowing 32 registers to be addressed within each PHY. Refer to the 10/100 PHY address map for addresses of individual registers.

Turnaround

An idle bit time during which no device actively drives the MDIO_DATA signal shall be inserted between the register address field and the data field of a read frame in order to avoid contention. During a read frame, the PHY shall drive a zero bit onto MDIO_DATA for the first bit time following the idle bit and preceding the Data field. During a write frame, this field shall consist of a one bit followed by a zero bit.

Data

The Data field is 16 bits. The first bit transmitted and received is the MSB of the data word.

15.3.8.2 Functional Description

The MII Management I/F will remain idle until enabled by setting the enable bit in the MDIOCTRL register. The MII Management I/F will then continuously poll the link status from within the Generic Status Register of all possible 32 PHY addresses in turn recording the results in the MDIO link register.

The linksel bit in the MDIOUserPhySel register determines the status input that is used. A change in the link status of the two PHYs being monitored will set the appropriate bit in the MDIOLinkIntRaw register and the MDIOLinkIntMasked register, if enabled by the linkint_enable bit in the MDIOUserPhySel register.

The MDIO Alive register is updated by the MII Management I/F module if the PHY acknowledged the read of the generic status register. In addition, any PHY register read transactions initiated by the host also cause the MDIOAlive register to be updated.

At any time, the host can define a transaction for the MII Management interface module to undertake using the data, phyadr, regadr, and write fields in a MDIOUserAccess register. When the host sets the go bit in this register, the MII Management interface module will begin the transaction without any further intervention from the host. Upon completion, the MII Management interface will clear the go bit and set the userintraw bit in the MDIOUserIntRaw register corresponding to the MDIOUserAccess register being used.

The corresponding bit in the MDIOUserIntMasked register may also be set depending on the mask setting in the MDIOUserIntMaskSet and MDIOUserIntMaskClr registers. A round-robin arbitration scheme is used to schedule transactions which may queued by the host in different MDIOUserAccess registers. The host should check the status of the go bit in the MDIOUserAccess register before initiating a new transaction to ensure that the previous transaction has completed. The host can use the ack bit in the MDIOUserAccess register to determine the status of a read transaction.

It is necessary for software to use the MII Management interface module to setup the auto-negotiation parameters of each PHY attached to a MAC port, retrieve the negotiation results, and setup the MACCTRL register in the corresponding MAC.

15.4 Software Operation

15.4.1 Transmit Operation

After reset the host must write zeroes to all Tx DMA State head descriptor pointers. The Tx port may then be enabled. To initiate packet transmission the host constructs transmit queues in memory (one or more packets for transmission) and then writes the appropriate Tx DMA state head descriptor pointers. For each buffer added to a transmit queue, the host must initialize the Tx buffer descriptor values as follows:

1. Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor).
2. Write the Buffer Pointer with the byte aligned address of the buffer data.
3. Write the Buffer Length with the number of bytes in the buffer.
4. Write the Buffer Offset with the number of bytes in the offset to the data (nonzero with SOP only).
5. Set the SOP, EOP, and Ownership bits as appropriate.
6. Clear the End Of Queue bit.

The port begins Tx packet transmission on a given channel when the host writes the channel's Tx queue head descriptor pointer with the address of the first buffer descriptor in the queue (nonzero value). Each channel may have one or more queues, so each channel may have one or more head descriptor pointers. The first buffer descriptor for each Tx packet must have the Start of Packet (SOP) bit and the Ownership bit set to one by the host. The last buffer descriptor for each Tx packet must have the End of Packet (EOP) bit set to one by the host.

The port will transmit packets until all queued packets have been transmitted and the queue(s) are empty. When each packet transmission is complete, the port will clear the Ownership bit in the packet's SOP buffer descriptor and issue an interrupt to the host by writing the packet's last buffer descriptor address to the queue's Tx DMA State Completion Pointer. The interrupt is generated by the write, regardless of the value written.

When the last packet in a queue has been transmitted, the port sets the End Of Queue bit in the EOP buffer descriptor, clears the Ownership bit in the SOP Descriptor, zeroes the appropriate DMA state head descriptor pointer, and then issues a Tx interrupt to the host by writing to the queue's associated Tx completion pointer (address of the last buffer descriptor processed by the port). The port issues a maskable level interrupt (which may then be routed through external interrupt control logic to the host).

On interrupt from the port, the host processes the buffer queue, detecting transmitted packets by the status of the Ownership bit in the SOP buffer descriptor. If the Ownership bit is cleared to zero, then the packet has been transmitted and the host may reclaim the buffers associated with the packet. The host continues queue processing until the end of the queue or until a SOP buffer descriptor is read that contains a set Ownership bit indicating that the packet transmission is not complete.

The host determines that all packets in the queue have been transmitted when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, the End of Queue bit is set in the last packet EOP buffer descriptor, and the Next Descriptor Pointer of the last packet EOP buffer descriptor is zero. The host acknowledges an interrupt by writing the address of the last buffer descriptor to the queue's associated Tx Completion Pointer in the Tx DMA State.

If the host written buffer address value is different from the buffer address written by the port, then the level interrupt remains asserted. If the host written buffer address value is equal to the port written value, then the level interrupt is deasserted. The port write to the completion pointer actually stores the value in the state register (ram). The host written value is actually not written to the register location. The host written value is compared to the register contents (which was written by the port) and if the two values are equal, the interrupt is removed, otherwise the interrupt remains asserted. The host may process multiple packets previous to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

A misqueued packet condition may occur when the host adds a packet to a queue for transmission as the port finishes transmitting the previous last packet in the queue. The misqueued packet is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor.

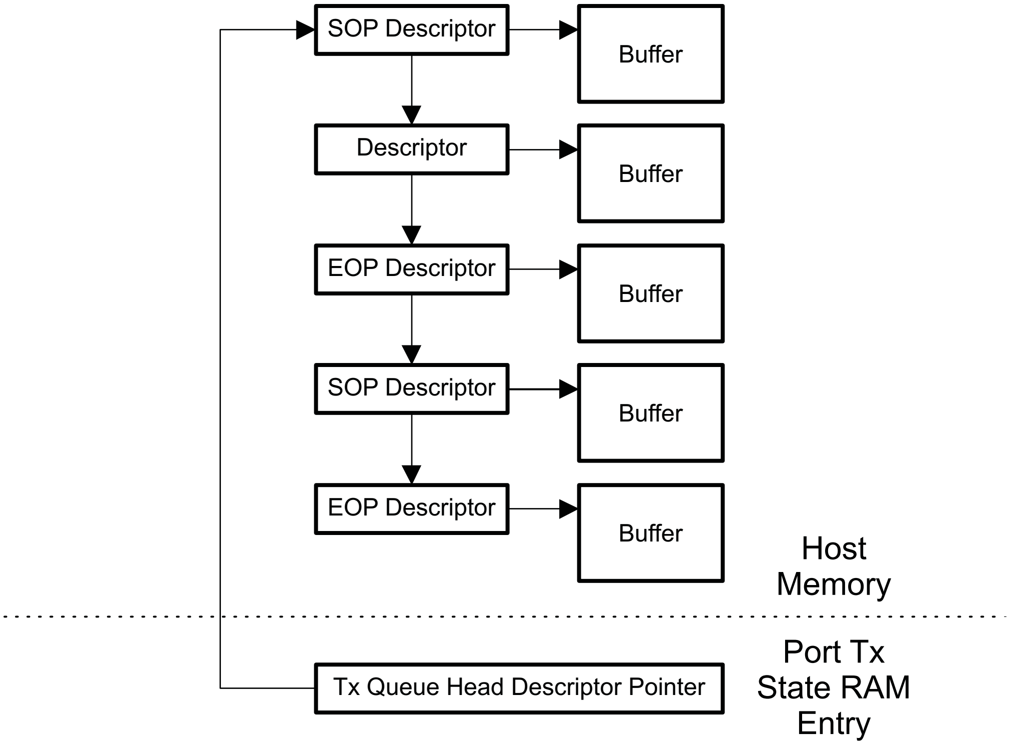
A misqueued packet means that the port read the last EOP buffer descriptor before the host added the new last packet to the queue, so the port determined queue empty just before the last packet was added. The host corrects the misqueued packet condition by initiating a new packet transfer for the misqueued packet by writing the misqueued packet's SOP buffer descriptor address to the appropriate DMA State Tx Queue head Descriptor Pointer.

The host may add packets to the tail end of an active Tx queue at any time by writing the Next Descriptor Pointer to the current last descriptor in the queue. If a Tx queue is empty (inactive), the host may initiate packet transmission at any time by writing the appropriate Tx DMA State head descriptor pointer.

The host software should always check for and reinitiate transmission for misqueued packets during queue processing on interrupt from the port. In order to preclude software underrun, the host should avoid adding buffers to an active queue for any Tx packet that is not complete and ready for transmission.

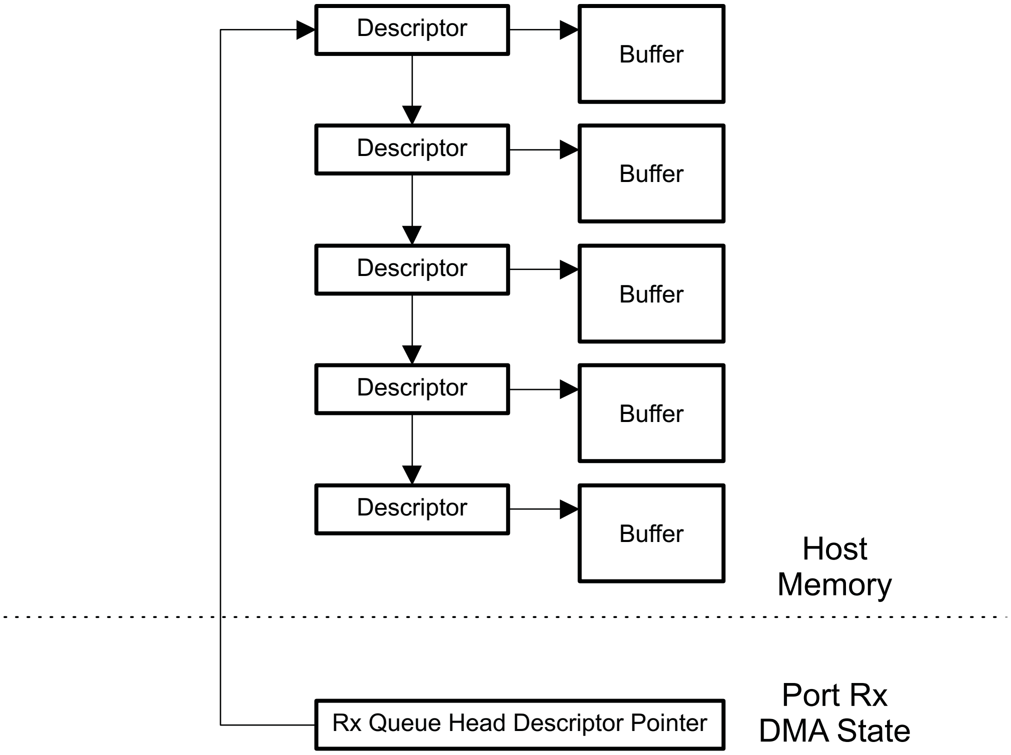
The port determines that a packet is the last packet in the queue by detecting the End of Packet bit set with a zero Next Descriptor Pointer in the packet buffer descriptor. If the End of Packet bit is set and the Next Descriptor Pointer is nonzero, then the queue still contains one or more packets to be transmitted. If the EOP bit is set with a zero Next Descriptor Pointer, then the port will set the EOQ bit in the packet's EOP buffer descriptor and then zero the appropriate head descriptor pointer previous to interrupting the port (by writing the completion pointer) when the packet transmission is complete.

Figure 15-13. Port TX State RAM Entry



15.4.2 Receive Operation

Figure 15-14. Port RX DMA State



After reset the host must write zeroes to all Rx DMA State head descriptor pointers. The Rx port may then be enabled. To initiate packet reception, the host constructs receive queues in memory and then writes the appropriate Rx DMA state head descriptor pointer. For each Rx buffer descriptor added to the queue, the host must initialize the Rx buffer descriptor values as follows:

- Write the Next Descriptor Pointer with the 32-bit aligned address of the next descriptor in the queue (zero if last descriptor)
- Write the Buffer Pointer with the byte aligned address of the buffer data
- Clear the Offset field
- Write the Buffer Length with the number of bytes in the buffer
- Clear the SOP, EOP, and EOQ bits
- Set the Ownership bit

The host enables packet reception on a given channel by writing the address of the first buffer descriptor in the queue (nonzero value) to the channel's head descriptor pointer in the channel's Rx DMA state. When packet reception begins on a given channel, the port fills each Rx buffer with data in order starting with the first buffer and proceeding through the Rx queue. If the Buffer Offset in the Rx DMA State is nonzero, then the port will begin writing data after the offset number of bytes in the SOP buffer. The port performs the following operations at the end of each packet reception:

- Overwrite the buffer length in the packet's EOP buffer descriptor with the number of bytes actually received in the packet's last buffer. The host initialized value is the buffer size. The overwritten value will be less than or equal to the host initialized value.
- Set the EOP bit in the packet's EOP buffer descriptor.
- Set the EOQ bit in the packet's EOP buffer descriptor if the current packet is the last packet in the queue.
- Overwrite the packet's SOP buffer descriptor Buffer Offset with the Rx DMA state value (the host initialized the buffer descriptor Buffer Offset value to zero). All non SOP buffer descriptors must have a zero Buffer Offset initialized by the host.

- Overwrite the packet's SOP buffer descriptor buffer length with the number of valid data bytes in the buffer. If the buffer is filled up, the buffer length will be the buffer size minus buffer offset.
- Set the SOP bit in the packet's SOP buffer descriptor.
- Write the SOP buffer descriptor Packet Length field.
- Clear the Ownership bit in the packet's SOP buffer descriptor.
- Issue an Rx host interrupt by writing the address of the packet's last buffer descriptor to the queue's Rx DMA State Completion Pointer. The interrupt is generated by the write to the Rx DMA State Completion Pointer address location, regardless of the value written.

On interrupt the host processes the Rx buffer queue detecting received packets by the status of the Ownership bit in each packet's SOP buffer descriptor. If the Ownership bit is cleared then the packet has been completely received and is available to be processed by the host.

The host may continue Rx queue processing until the end of the queue or until a buffer descriptor is read that contains a set Ownership bit indicating that the next packet's reception is not complete. The host determines that the Rx queue is empty when the last packet in the queue has a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and the Next Descriptor Pointer in the EOP buffer descriptor is zero.

A misqueued buffer may occur when the host adds buffers to a queue as the port finishes the reception of the previous last packet in the queue. The misqueued buffer is detected by the host when queue processing detects a cleared Ownership bit in the SOP buffer descriptor, a set End of Queue bit in the EOP buffer descriptor, and a nonzero Next Descriptor Pointer in the EOP buffer descriptor.

A misqueued buffer means that the port read the last EOP buffer descriptor before the host added buffer descriptor(s) to the queue, so the port determined queue empty just before the host added more buffer descriptor(s). In the transmit case, the packet transmission is delayed by the time required for the host to determine the condition and reinitiate the transaction, but the packet is not actually lost. In the receive case, receive overrun condition may occur in the misqueued buffer case.

If a new packet reception is begun during the time that the port has determined the end of queue condition, then the received packet will overrun (start of packet overrun). If the misqueued buffer occurs during the middle of a packet reception then middle of packet overrun may occur. If the misqueued buffer occurs after the last packet has completed, and is corrected before the next packet reception begins, then overrun will not occur. The host acts on the misqueued buffer condition by writing the added buffer descriptor address to the appropriate Rx DMA State Head Descriptor Pointer.

15.4.3 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO control register (MDIOCTRL).
2. Enable the MDIO module by setting the EN bit in MDIOCTRL.
3. The MDIO PHY alive status register (MDIOALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (MDIOLINK) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register (MDIOUSERPHYSEL*n*), and set the LINKINTENB bit to enable a link change event interrupt if desirable.

- If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (MDIOUSERINTMASKSET) to use the MDIO user access register (MDIOUSERACCESS*n*). Since only one PHY is used in this device, the application software can use one MDIOUSERACCESS*n* to trigger a completion interrupt; the other MDIOUSERACCESS*n* is not setup.

15.4.4 Writing Data to a PHY Register

The MDIO module includes a user access register (MDIOUSERACCESS*n*) to directly access a specified PHY device.To write a PHY register, perform the following:

1. Ensure that the GO bit in the MDIO user access register (MDIOUSERACCESS*n*) is cleared.

2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in MDIOUSERACCESS*n* corresponding to the PHY and PHY register you want to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in MDIOUSERACCESS*n* for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (MDIOUSERINTRAW) corresponding to USERACCESS*n* used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (MDIOUSERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (MDIOUSERINTMASKED) and an interrupt is triggered on the CPU.

15.4.5 Reading Data from a PHY Register

The MDIO module includes a user access register (MDIOUSERACCESS*n*) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Ensure that the GO bit in the MDIO user access register (MDIOUSERACCESS*n*) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in MDIOUSERACCESS*n* corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in MDIOUSERACCESS*n* after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in MDIOUSERACCESS*n*. After the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (MDIOUSERINTRAW) corresponding to USERACCESS*n* used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (MDIOUSERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (MDIOUSERINTMASKED) and an interrupt is triggered on the CPU.

15.4.6 Initialization and Configuration of CPSW

To configure the 3PSW Ethernet Subsystem for operation the host must perform the following:

- Select the Interface (GMII/RGMII/MII) Mode in the Control Module.
- Configure pads (PIN muxing) as per the Interface Selected using the appropriate pin muxing conf_xxx registers in the Control Module.
- Enable the 3PSW Ethernet Subsystem Clocks. See Section 15.2.2 and to enable the appropriate clocks.
- Configure the PRCM Registers CM_PER_CPSW_CLKSTCTRL and CM_PER_CPSW_CLKSTCTRL to enable power and clocks to the 3PSW Ethernet Subsystem. See Section 6.13.6 for register details.
- Apply soft reset to 3PSW Subsytem, CPSW_3G, CPGMAC_SL1/2, and CPDMA (see the soft reset registers in the following sections).
- Initialize the HDPs (Header Description Pointer) and CPs (Completion Pointer) to NULL
- Configure the Interrupts (see Chapter 8).
- Configure the CPSW_3G Control register.
- Configure the Statistics Port Enable register
- Configure the ALE. (See Section 15.3.2.7.)
- Configure the MDIO.
- Configure the CPDMA receive DMA controller.
- Configure the CPDMA transmit DMA controller.
- Configure the CPPI Tx and Rx Descriptors.
- Configure CPGMAC_SL1 and CPGMAC_SL2 as per the desired mode of operations.
- Start up RX and TX DMA (write to HDP of Rx and Tx).
- Wait for the completion of the transfer (HDP cleared to zero).

15.5 Ethernet Subsystem Registers

15.5.1 CPSW_ALE Registers

Table 15-23 lists the memory-mapped registers for the CPSW_ALE. All register offset addresses not listed in Table 15-23 should be considered as reserved locations and the register contents should not be modified.

Table 15-23. CPSW_ALE Registers

Offset	Acronym	Register Name	Section
0h	CPSW_ALE_IDVER	ADDRESS LOOKUP ENGINE ID/VERSION REGISTER	Section 15.5.1.1

Table 15-25. CPSW_ALE_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	EN_ALE	R/W	0h	Enable ALE 0h = Drop all packets 1h = Enable ALE packet processing
30	CLR_TBL	R/W	0h	Clear ALE address table - Setting this bit causes the ALE hardware to write all table bit values to zero. Software must perform a clear table operation as part of the ALE setup/configuration process. Setting this bit causes all ALE accesses to be held up for 64 clocks while the clear is performed. Access to all ALE registers will be blocked (wait states) until the 64 clocks have completed. This bit cannot be read as one because the read is blocked until the clear table is completed at which time this bit is cleared to zero.
29	AGE_OUT_NOW	R/W	0h	Age Out Address Table Now - Setting this bit causes the ALE hardware to remove (free up) any ageable table entry that does not have a set touch bit. This bit is cleared when the age out process has completed. This bit may be read. The age out process takes 4096 clocks best case (no ale packet processing during ageout) and 66550 clocks absolute worst case.
28-9	RESERVED	R	0h	
8	EN_P0_UNI_FLOOD	R/W	0h	Enable Port 0 (Host Port) unicast flood 0h = Do not flood unknown unicast packets to host port (p0) 1h = Flood unknown unicast packets to host port (p0)
7	LEARN_NO_VID	R/W	0h	Learn No VID 0h = VID is learned with the source address 1h = VID is not learned with the source address (source address is not tied to VID).
6	EN_VID0_MODE	R/W	0h	Enable VLAN ID = 0 Mode 0h = Process the packet with VID = PORT_VLAN[11 to 0] 1h = Process the packet with VID = 0.

Table 15-25. CPSW_ALE_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	EN_OUI_DENY	R/W	0h	Enable OUI Deny Mode - When set this bit indicates that a packet with a non OUI table entry matching source address will be dropped to the host unless the destination address matches a multicast table entry with the super bit set.
4	BYPASS	R/W	0h	ALE Bypass - When set, all packets received on ports 0 and 1 are sent to the host (only to the host).
3	RATE_LIMIT_TX	R/W	0h	Rate Limit Transmit mode 0h = Broadcast and multicast rate limit counters are received port based 1h = Broadcast and multicast rate limit counters are transmit port based
2	VLAN_AWARE	R/W	0h	ALE VLAN Aware - Determines what is done if VLAN not found. 0h = Flood if VLAN not found 1h = Drop packet if VLAN not found
1	EN_AUTH_MODE	R/W	0h	Enable MAC Authorization Mode - Mac authorization mode requires that all table entries be made by the host software. There are no learned address in authorization mode and the packet will be dropped if the source address is not found (and the destination address is not a multicast address with the super table entry bit set). 0h = The ALE is not in MAC authorization mode. 1h = The ALE is in MAC authorization mode.
0	EN_RATE_LIMIT	R/W	0h	Enable Broadcast and Multicast Rate Limit 0h = Broadcast/Multicast rates not limited 1h = Broadcast/Multicast packet reception limited to the port control register rate limit fields

15.5.1.3 CPSW_ALE_PRESCALE Register (offset = 10h) [reset = 0h]

CPSW_ALE_PRESCALE is shown in Figure 15-17 and described in Table 15-26.

ADDRESS LOOKUP ENGINE PRESCALE REGISTER

Table 15-32. CPSW_ALE_PORTCTL_0 to CPSW_ALE_PORTCTL_5 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-24	BCAST_LIMIT	R/W	0h	Broadcast Packet Rate Limit - Each prescale pulse loads this field into the port broadcast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Broadcast rate limiting is enabled by a non-zero value in this field
23-16	MCAST_LIMIT	R/W	0h	Multicast Packet Rate Limit - Each prescale pulse loads this field into the port multicast rate limit counter. The port counters are decremented with each packet received or transmitted depending on whether the mode is transmit or receive. If the counters decrement to zero, then further packets are rate limited until the next prescale pulse. Multicast rate limiting is enabled by a non-zero value in this field.
15-6	RESERVED	R	0h	
5	NO_SA_UPDATE	R/W	0h	No Souce Address Update - When set the port is disabled from updating the source port number in an ALE table entry.
4	NO_LEARN	R/W	0h	No Learn Mode - When set the port is disabled from learning an address.
3	VID_INGRESS_CHECK	R/W	0h	VLAN ID Ingress Check - If VLAN not found then drop the packet. Packets with an unknown (default) VLAN will be dropped.
2	DROP_UNTAGGED	R/W	0h	Drop Untagged Packets - Drop non-VLAN tagged ingress packets.
1-0	PORT_STATE	R/W	0h	0h (R/W) = Disabled 1h (R/W) = Blocked 2h (R/W) = Learn 3h (R/W) = Forward

15.5.2 CPSW_CPDMA Registers

Table 15-33 lists the memory-mapped registers for the CPSW_CPDMA. All register offset addresses not listed in Table 15-33 should be considered as reserved locations and the register contents should not be modified.

Table 15-41. CPSW_DMACTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-8	TX_RLIM	R/W	0h	Transmit Rate Limit Channel Bus 00000000 - no rate-limited channels 10000000 - channel 7 is rate-limited 11000000 - channels 7 downto 6 are rate-limited 11100000 - channels 7 downto 5 are rate-limited 11110000 - channels 7 downto 4 are rate-limited 11111000 - channels 7 downto 3 are rate-limited 11111100 - channels 7 downto 2 are rate-limited 11111110 - channels 7 downto 1 are rate-limited 11111111 - channels 7 downto 0 are rate-limited all others invalid - this bus must be set msb towards lsb. tx_ptype must be set if any tx_rlim bit is set for fixed priority.
7-5	RESERVED	R	0h	
4	RX_CEF	R/W	0h	RX Copy Error Frames Enable - Enables DMA overrun frames to be transferred to memory (up to the point of overrun). The overrun error bit will be set in the frame EOP buffer descriptor. Overrun frame data will be filtered when rx_cef is not set. Frames coming from the receive FIFO with other error bits set are not effected by this bit. 0h = Frames containing overrun errors are filtered 1h = Frames containing overrun errors are transferred to memory
3	CMD_IDLE	R/W	0h	Command Idle 0h = Idle not commanded 1h = Idle Commanded (read idle in DMAStatus)
2	RX_OFFLEN_BLOCK	R/W	0h	Receive Offset/Length word write block. 0h = Do not block the DMA writes to the receive buffer descriptor offset/buffer length word. The offset/buffer length word is written as specified in CPPI 3.0. 1h = Block all CPDMA DMA controller writes to the receive buffer descriptor offset/buffer length words during CPPI packet processing. when this bit is set, the CPDMA will never write the third word to any receive buffer descriptor.

Table 15-41. CPSW_DMACTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
1	RX_OWNERSHIP	R/W	0h	Receive Ownership Write Bit Value. 0h = The CPDMA writes the receive ownership bit to zero at the end of packet processing as specified in CPPI 3.0. 1h = The CPDMA writes the receive ownership bit to one at the end of packet processing. Users who do not use the ownership mechanism can use this mode to preclude the necessity of software having to set this bit each timethe buffer descriptor is used.
0	TX_PTYPE	R/W	0h	Transmit Queue Priority Type 0h = The queue uses a round robin scheme to select the next channel for transmission. 1h = The queue uses a fixed (channel 7 highest priority) priority scheme to select the next channel for transmission

15.5.2.9 CPSW_DMASTS Register (offset = 24h) [reset = 0h]

CPSW_DMASTS is shown in Figure 15-32 and described in Table 15-42.

Table 15-42. CPSW_DMASTS Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IDLE	R	0h	Idle Status Bit - Indicates when set that the CPDMA is not transferring a packet on transmit or receive.
30-24	RESERVED	R	0h	
23-20	TX_HOST_ERR_CODE	R	0h	TX Host Error Code - This field is set to indicate CPDMA detected TX DMA related host errors. The host should read this field after a HOST_ERR_INT to determine the error. Host error Interrupts require hardware reset in order to recover. A zero packet length is an error, but it is not detected. 0000 - No error 0001 - SOP error. 0010 - Ownership bit not set in SOP buffer. 0011 - Zero Next Buffer Descriptor Pointer Without EOP 0100 - Zero Buffer Pointer. 0101 - Zero Buffer Length 0110 - Packet Length Error (sum of buffers is less than packet length) 0111 - reserved ... 1111 - reserved
19	RESERVED	R	0h	
18-16	TX_ERR_CH	R	0h	TX Host Error Channel - This field indicates which TX channel (if applicable) the host error occurred on. This field is cleared to zero on a host read. 000 - The host error occurred on TX channel 0 ... 111 - The host error occurred on TX channel 7
15-12	RX_HOST_ERR_CODE	R	0h	RX Host Error Code - This field is set to indicate CPDMA detected RX DMA related host errors. The host should read this field after a HOST_ERR_INT to determine the error. Host error Interrupts require hardware reset in order to recover. 0000 - No error 0001 - reserved 0010 - Ownership bit not set in input buffer. 0011 - reserved 0100 - Zero Buffer Pointer. 0101 - Zero buffer length on non-SOP descriptor 0110 - SOP buffer length not greater than offset ... 1111 - reserved
11	RESERVED	R	0h	

Table 15-42. CPSW_DMASTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10-8	RX_ERR_CH	R	0h	RX Host Error Channel - This field indicates which RX channel the host error occurred on. This field is cleared to zero on a host read. 000 - The host error occurred on RX channel 0 ... 111 - The host error occurred on RX channel 7
7-0	RESERVED	R	0h	

15.5.2.10 CPSW_RX_BUFFER_OFFSET Register (offset = 28h) [reset = 0h]

CPSW_RX_BUFFER_OFFSET is shown in Figure 15-33 and described in Table 15-43.

CPDMA_REGS RECEIVE BUFFER OFFSET

Figure 15-33. CPSW_RX_BUFFER_OFFSET Register

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>

Table 15-43. CPSW_RX_BUFFER_OFFSET Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-0	RX_BUFFER_OFFSET	R/W	0h	Receive Buffer Offset Value - The rx_buffer_offset will be written by the port into each frame SOP buffer descriptor buffer_offset field. The frame data will begin after the rx_buffer_offset value of bytes. A value of 0x0000 indicates that there are no unused bytes at the beginning of the data and that valid data begins on the first byte of the buffer. A value of 0x000F (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels.

15.5.2.11 CPSW_EMCTRL Register (offset = 2Ch) [reset = 0h]

CPSW_EMCTRL is shown in Figure 15-34 and described in Table 15-44.

Table 15-75. CPSW_RX0_FREEBUFFER Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-0	RX_FREEBUFFER	W	0h	Rx Free Buffer Count - This field contains the count of free buffers available. The rx_pendthresh value is compared with this field to determine if the receive threshold pending interrupt should be asseted (if enabled). This is a write to increment field. This field rolls over to zero on overflow. If receive threshold pending interrupts are used, the host must initialize this field to the number of available buffers (one register per channel). The port decrements (by the number of buffers in the received frame) the associated channel register for each received frame. This is a write to increment field. The host must write this field with the number of buffers that have been freed due to host processing.

15.5.2.43 CPSW_RX1_FREEBUFFER Register (offset = E4h) [reset = 0h]

CPSW_RX1_FREEBUFFER is shown in Figure 15-66 and described in Table 15-76.

7	6	5	4	3	2	1	0
RESERVED							TS_PUSH
R-0h							W-0h

Table 15-87. CPSW_CPTS_PUSH Register Field Descriptions

Bit	Field	Type	Reset	Description
31-1	RESERVED	R	0h	
0	TS_PUSH	W	0h	Time stamp event push - When a logic high is written to this bit a time stamp event is pushed onto the event FIFO. The time stamp value is the time of the write of this register, not the time of the event read. The time stamp value can then be read on interrupt via the event registers. Software should not push a second time stamp event onto the event FIFO until the first time stamp value has been read from the event FIFO (there should be only one time stamp event in the event FIFO at any given time). This bit is write only and always reads zero.

15.5.3.5 CPSW_CPTS_LOAD_VAL Register (offset = 10h) [reset = 0h]

CPSW_CPTS_LOAD_VAL is shown in Figure 15-77 and described in Table 15-88.

TIME STAMP LOAD VALUE REGISTER

TS_LOAD_VAL																															
R/W-0h																															

Table 15-88. CPSW_CPTS_LOAD_VAL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	TS_LOAD_VAL	R/W	0h	Time Stamp Load Value - Writing the ts_load_en bit causes the value contained in this register to be written into the time stamp. The time stamp value is read by initiating a time stamp push event, not by reading this register. When reading this register, the value read is not the time stamp, but is the value that was last written to this register.

15.5.3.6 CPSW_CPTS_LOAD_EN Register (offset = 14h) [reset = 0h]

CPSW_CPTS_LOAD_EN is shown in Figure 15-78 and described in Table 15-89.

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	
8-4	P2_TX_MAX_BLKS	R/W	11h	Transmit FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical transmit priority queues. 0x11 is the recommended value of p2_tx_max_blks unless the port is in fullduplex flow control mode. In flow control mode, the p2_rx_max_blks will need to increase in order to accept the required run out in fullduplex mode. This value will need to decrease by the amount of increase in p2_rx_max_blks. 0xe is the minimum value tx max blks.
3-0	P2_RX_MAX_BLKS	R/W	3h	Receive FIFO Maximum Blocks - This value is the maximum number of 1k memory blocks that may be allocated to the FIFO's logical receive queue. This value must be greater than or equal to 0x3. It should be increased In fullduplex flow control mode to 0x5 or 0x6 depending on the required runout space. The p2_tx_max_blks value must be decreased by the amount of increase in p2_rx_max_blks. 0x3 is the minimum value rx max blks and 0x6 is the maximum value.

15.5.6.39 CPSW_PORT_P2_BLK_CNT Register (offset = 20Ch) [reset = 41h]

CPSW_PORT_P2_BLK_CNT is shown in Figure 15-158 and described in Table 15-172.

Table 15-190. CPSW_SL_MACCTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	RESERVED	R	0h	
24	RX_CMF_EN	R/W	0h	RX Copy MAC Control Frames Enable - Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in the MacControl register, regardless of the value of rx_cmf_en. Frames transferred to memory due to rx_cmf_en will have the control bit set in their EOP buffer descriptor. 0h (R/W) = MAC control frames are filtered (but acted upon if enabled). 1h (R/W) = MAC control frames are transferred to memory.
23	RX_CSF_EN	R/W	0h	RX Copy Short Frames Enable - Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to rx_csf_en will have the fragment or undersized bit set in their receive footer. Fragments are short frames that contain CRC/align/code errors and undersized are short frames without errors. 0h (R/W) = Short frames are filtered 1h (R/W) = Short frames are transferred to memory.
22	RX_CEF_EN	R/W	0h	RX Copy Error Frames Enable - Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame receive footer. Frames containing errors will be filtered when rx_cef _en is not set. 0h (R/W) = Frames containing errors are filtered. 1h (R/W) = Frames containing errors are transferred to memory.
21	TX_SHORT_GAP_LIM_EN	R/W	0h	Transmit Short Gap Limit Enable When set this bit limits the number of short gap packets transmitted to 100ppm. Each time a short gap packet is sent, a counter is loaded with 10,000 and decremented on each wireside clock. Another short gap packet will not be sent out until the counter decrements to zero. This mode is included to preclude the host from filling up the FIFO and sending every packet out with short gap which would violate the maximum number of packets per second allowed.

Table 15-190. CPSW_SL_MACCTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20-19	RESERVED	R	0h	
18	EXT_EN	R/W	0h	Control Enable - Enables the fullduplex and gigabit mode to be selected from the FULLDUPLEX_IN and GIG_IN input signals and not from the fullduplex and gig bits in this register. The FULLDUPLEX_MODE bit reflects the actual fullduplex mode selected.
17	GIG_FORCE	R/W	0h	Gigabit Mode Force - This bit is used to force the CPGMAC_SL into gigabit mode if the input GMII_MTCLK has been stopped by the PHY.
16	IFCTL_B	R/W	0h	Connects to the speed_in input of the respective RMII gasket. When using RMII mode: 0h (R/W) = 10Mbps operation 1h (R/W) = 100Mbps operation
15	IFCTL_A	R/W	0h	Connects to the speed_in input of the respective RMII gasket. When using RMII mode: 0h (R/W) = 10Mbps operation 1h (R/W) = 100Mbps operation
14-13	RESERVED	R	0h	
12	CRS_FLOW_EN	R/W	0h	Carrier Sense Flow Control Enable When set this bit enables the GMII_MCRS (carrier sense) to be used as a hardware flow control in fullduplex mode.
11	CMD_IDLE	R/W	0h	Command Idle 0h (R/W) = Idle not commanded 1h (R/W) = Idle Commanded (read idle in MacStatus)
10	TX_SHORT_GAP_EN	R/W	0h	Transmit Short Gap Enable 0h (R/W) = Transmit with a short IPG is disabled 1h (R/W) = Transmit with a short IPG (when TX_SHORT_GAP input is asserted) is enabled.
9-8	RESERVED	R	0h	
7	GIG	R/W	0h	Gigabit Mode 0h (R/W) = 10/100 mode 1h (R/W) = Gigabit mode (full duplex only) The GIG_OUT output is the value of this bit.
6	TX_PACE	R/W	0h	Transmit Pacing Enable 0h (R/W) = Transmit Pacing Disabled 1h (R/W) = Transmit Pacing Enabled
5	GMII_EN	R/W	0h	GMII Enable. This bit must be set before the MAC will transmit or receive data in any of the supported interface modes. (ex. MII, RMII). This bit does not select the interface mode but rather holds or releases the MAC TX and RX state machines from reset. 0h (R/W) = The MAC RX and TX state machines are held in reset. 1h (R/W) = The MAC RX and TX state machines are released from reset and transmit/receive are enabled.
4	TX_FLOW_EN	R/W	0h	Transmit Flow Control Enable - Determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode regardless of this bit setting. The RX_MBP_Enable bits determine whether or not received pause frames are transferred to memory. 0h (R/W) = Transmit Flow Control Disabled. Full-duplex mode - Incoming pause frames are not acted upon. 1h (R/W) = Transmit Flow Control Enabled. Full-duplex mode - Incoming pause frames are acted upon.

Table 15-190. CPSW_SL_MACCTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	RX_FLOW_EN	R/W	0h	Receive Flow Control Enable 0h (R/W) = Receive Flow Control Disabled Half-duplex mode - No flow control generated collisions are sent. Full-duplex mode - No outgoing pause frames are sent. 1h (R/W) = Receive Flow Control Enabled Half-duplex mode - Collisions are initiated when receive flow control is triggered. Full-duplex mode - Outgoing pause frames are sent when receive flow control is triggered.
2	MTEST	R/W	0h	Manufacturing Test mode - This bit must be set to allow writes to the Backoff_Test and PauseTimer registers.
1	LOOPBACK	R/W	0h	Loop Back Mode - Loopback mode forces internal fullduplex mode regardless of whether the fullduplex bit is set or not. The loopback bit should be changed only when GMII_en is deasserted. 0h (R/W) = Not looped back 1h (R/W) = Loop Back Mode enabled
0	FULLDUPLEX	R/W	0h	Full Duplex mode - Gigabit mode forces fullduplex mode regardless of whether the fullduplex bit is set or not. The FULLDUPLEX_OUT output is the value of this register bit 0h (R/W) = Half duplex mode 1h (R/W) = Full duplex mode

15.5.7.3 CPSW_SL_MACSTS Register (Offset = 8h) [reset = 80000000h]

CPSW_SL_MACSTS is shown in Figure 15-176 and described in Table 15-191.

Return to Summary Table.

Table 15-191. CPSW_SL_MACSTS Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IDLE	R	1h	CPGMAC_SL IDLE - The CPGMAC_SL is in the idle state (valid after an idle command) 0h (R/W) = The CPGMAC_SL is not in the idle state. 1h (R/W) = The CPGMAC_SL is in the idle state.
30-5	RESERVED	R	0h	
4	EXT_GIG	R	0h	External GIG - This is the value of the EXT_GIG input bit.
3	EXT_FULLDUPLEX	R	0h	External Fullduplex - This is the value of the EXT_FULLDUPLEX input bit.
2	RESERVED	R	0h	
1	RX_FLOW_ACT	R	0h	Receive Flow Control Active - When asserted, indicates that receive flow control is enabled and triggered.
0	TX_FLOW_ACT	R	0h	Transmit Flow Control Active - When asserted, this bit indicates that the pause time period is being observed for a received pause frame. No new transmissions will begin while this bit is asserted except for the transmission of pause frames. Any transmission in progress when this bit is asserted will complete.

15.5.7.4 CPSW_SL_SOFT_RESET Register (Offset = Ch) [reset = 0h]

CPSW_SL_SOFT_RESET is shown in Figure 15-177 and described in Table 15-192.

Return to Summary Table.

TX_BACKOFF							
R-0h							

Table 15-194. CPSW_SL_BOFFTEST Register Field Descriptions

Bit	Field	Type	Reset	Description
31	RESERVED	R	0h	
30-26	PACEVAL	R/W	0h	Pacing Register Current Value. A non-zero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes paceval to loaded with decimal 31, good frame transmissions (with no collisions or deferrals) cause paceval to be decremented down to zero. When paceval is nonzero, the transmitter delays 4 IPGs between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. Transmit pacing helps reduce "capture" effects improving overall network bandwidth.
25-16	RNDNUM	R/W	0h	Backoff Random Number Generator - This field allows the Backoff Random Number Generator to be read (or written in test mode only). This field can be written only when mtest has previously been set. Reading this field returns the generator's current value. The value is reset to zero and begins counting on the clock after the deassertion of reset.
15-12	COLL_COUNT	R	0h	Collision Count - The number of collisions the current frame has experienced.
11-10	RESERVED	R	0h	
9-0	TX_BACKOFF	R	0h	Backoff Count - This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision.

15.5.7.7 CPSW_SL_RX_PAUSE Register (Offset = 18h) [reset = 0h]

CPSW_SL_RX_PAUSE is shown in Figure 15-180 and described in Table 15-195.

Return to Summary Table.

CPGMAC_SL RECEIVE PAUSE TIMER REGISTER

Figure 15-180. CPSW_SL_RX_PAUSE Register

<table>

<tr><td colspan="16">R-0h</td><td colspan="16">R-0h</td></tr>
</table>

Table 15-195. CPSW_SL_RX_PAUSE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-0	RX_PAUSETIMER	R	0h	RX Pause Timer Value - This field allows the contents of the receive pause timer to be observed (and written in test mode). The receive pause timer is loaded with 0xFF00 when the CPGMAC_SL sends an outgoing pause frame (with pause time of 0xFFFF). The receive pause timer is decremented at slot time intervals. If the receive pause timer decrements to zero, then another outgoing pause frame will be sent and the load/decrement process will be repeated.

15.5.7.8 CPSW_SL_TX_PAUSE Register (Offset = 1Ch) [reset = 0h]

CPSW_SL_TX_PAUSE is shown in Figure 15-181 and described in Table 15-196.

Return to Summary Table.

7	6	5	4	3	2	1	0
CLKDIV							
R/W-FFh							

Table 15-253. MDIO_CTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IDLE	R	1h	MDIO state machine IDLE. Set to 1 when the state machine is in the idle state. 0h = State machine is not in idle state. 1h = State machine is in idle state.
30	EN	R/W	0h	Enable control. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the idle bit. If using byte access, the enable bit has to be the last bit written in this register. 0h = Disables the MDIO state machine. 1h = Enable the MDIO state machine.
29	RESERVED1	R	0h	
28-24	HIGHEST_USER_CHANNEL	R	1h	Highest user channel. This field specifies the highest user access channel that is available in the module and is currently set to 1. This implies that the MDIOUSERACCESS1 register is the highest available user access channel.
23-21	RESERVED2	R	0h	
20	PREAMBLE	R/W	0h	Preamble disable. 0h = Standard MDIO preamble is used. 1h = Disables this device from sending MDIO frame preambles.
19	FAULT	R/WC	0h	Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to it clears this bit. 0h = No failure. 1h = Physical layer fault; the MDIO state machine is reset.
18	FAULTENB	R/W	0h	Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection. 0h = Disables the physical layer fault detection. 1h = Enables the physical layer fault detection.

Table 15-253. MDIO_CTRL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
17	INTTESTENB	R/W	0h	Interrupt test enable. This bit can be set to 1 to enable the host to set the USERINT and LINKINT bits for test purposes. 0h = Interrupt bits are not set. 1h = Enables the host to set the USERINT and LINKINT bits for test purposes.
16	RESERVED3	R	0h	
15-0	CLKDIV	R/W	FFh	Clock divider. This field specifies the division ratio between CLK and the frequency of MDIO_CLK. MDIO_CLK is disabled when clkdiv is set to 0. MDIO_CLK frequency = clk frequency/(clkdiv+1).

15.5.10.3 MDIO_ALIVE Register (offset = 8h) [reset = 0h]

MDIO_ALIVE is shown in Figure 15-236 and described in Table 15-254.

Table 15-254. MDIO_ALIVE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	ALIVE	R/WC	0h	MDIO alive. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY, the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address. Writing a 1 to any bit will clear it, writing a 0 has no effect.

15.5.10.4 MDIO_LINK Register (offset = Ch) [reset = 0h]

MDIO_LINK is shown in Figure 15-237 and described in Table 15-255.

Figure 15-237. MDIO_LINK Register

Table 15-255. MDIO_LINK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	LINK	R	0h	MDIO link state. This register is updated after a read of the Generic Status Register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect. In addition, the status of the two PHYs specified in the MDIOUSERPHYSEL registers can be determined using the MLINK input pins. This is determined by the LINKSEL bit in the MDIOUSERPHYSEL register.

15.5.10.5 MDIO_LINKINTRAW Register (offset = 10h) [reset = 0h]

MDIO_LINKINTRAW is shown in Figure 15-238 and described in Table 15-256.

Bit	Field	Type	Reset	Description
31-2	RESERVED1	R	0h	
1-0	LINKINTRAW	R/WC	0h	MDIO link change event, raw value. When asserted 1, a bit indicates that there was an MDIO link change event (that is, change in the MDIOLINK register) corresponding to the PHY address in the MDIOUSERPHYSEL register. LINKINTRAW[0] and LINKINTRAW[1] correspond to MDIOUSERPHYSEL0 and MDIOUSERPHYSEL1, respectively. Writing a 1 will clear the event and writing 0 has no effect. If the INTTESTENB bit in the MDIOCONTROL register is set, the host may set the LINKINTRAW bits to a 1. This mode may be used for test purposes.

15.5.10.6 MDIO_LINKINTMASKED Register (offset = 14h) [reset = 0h]

MDIO_LINKINTMASKED is shown in Figure 15-239 and described in Table 15-257.

Chapter 16

Universal Serial Bus (USB)

This chapter describes the universal serial bus (USB) of the device.

Topic **Page**

16.1 Introduction

USB (Universal Serial Bus) provides a low-cost connectivity solution for numerous consumer portable devices by implementing a mechanism for data transfer between USB devices.

The AM437x instantiates two independent instances of a third-party USB subsystem (USB2SS) operating at USB2.0 speeds (480Mb/s), either of which can be independently configured to act as a USB Host or a USB Device. SuperSpeed (5.0 Gb/s) operation is not supported in either operational mode.

This document serves to describe the integration of this third-party USB subsystem and should not be considered sufficient for those wishing to modify the existing Linux USB driver(s) or create a new driver to support this controller implementation. For those who do wish to substantially modify the existing Linux USB driver(s), or create new drivers, contact your TI sales representative for more information on how to obtain the third-party IP databook under NDA.

16.1.1 Features

The USB 2.0 subsystem, supports the following USB features:

- Operational modes:
  - Supports USB 2.0 Host mode at High-Speed (HS, 480 Mbps), Full-Speed (FS, 12 Mbps), and Low-Speed (LS, 1.5 Mbps)
  - Supports USB 2.0 Device mode at High-Speed (HS, 480 Mbps), and Full-Speed (FS, 12 Mbps). Low-Speed is not supported in Device mode.
  - Supports all modes of transfers - Control, Bulk, Interrupt, and Isochronous.
- A DRD (Dual-Role-Device - Host or Device) USB controller with the following features:
  - Compatible to the xHCI 1.0 specification in Host mode
  - Compatible with the USB 2.0 specification in Device mode
  - Supports 15 IN (Receive), 15 OUT (Transmit) endpoints (EPs), and one EP0 endpoint which is bidirectional
  - Internal DMA controller
  - Descriptor caching and data pre-fetching ensures high performance
  - Dynamic FIFO memory allocation for all endpoints
- Operation flexibility
  - Same programming model for HS, FS, and LS operation
  - Each controller instance can provide either USB Host or USB Device functionality
  - Multiple interrupt lines:
    - Four programmable interrupts
    - A MISC interrupt line for all miscellaneous events
- External requirements:
  - Needs an external Charge Pump for VBUS 5 V generation in Host mode. (Device mode does not require VBUS generation).

16.1.2 Unsupported Features

The following are USB features which are not supported:

- Battery Charger Support
- Accessory Charger Adaptor Support
- OTG functionality
- No Virtualization support
- SuperSpeed (5Gb/s) operation
- USB 2.0 ECN: Link Power Management (LPM)

16.2 Integration

Figure 16-1 shows the functional block diagram of the USB 2.0 subsystem (USB2SS), which includes a wrapper module, a USB controller module, a PHY module, external interfaces, and internal interfaces.

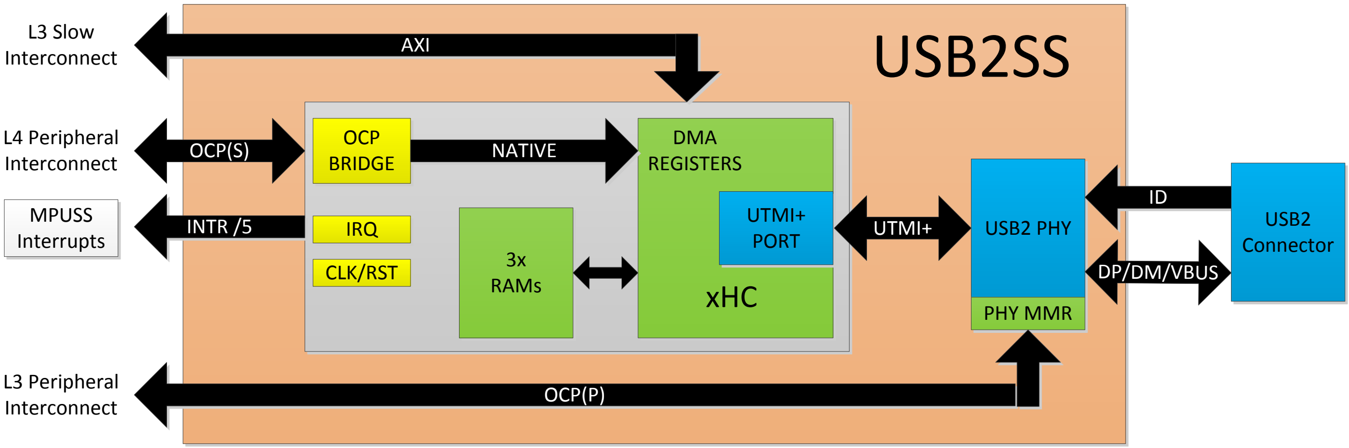

Figure 16-1. USB 2.0 Subsystem (USB2SS) Functional Block Diagram

- The wrapper module, which provides:
  - A bridge to the system bus
  - Local MMR to configure and control the USB controller
  - Interrupt management
- The USB Core with a Dual-Role-Device Controller module and internal RAMs:
  - Compatible to the xHCI 1.0 standard in Host mode
  - Support for either USB Host or USB Device modes
  - Internal DMA controller for high-bandwidth, low overhead data transfer
  - Three local RAMs supporting:
    - Dynamic Tx/Rx FIFO memory allocation for all EPs
    - Descriptor caching and data pre-fetching for high performance
  - Supports all transfer types - Control, Bulk, Interrupt, and Isochronous
  - Supports high-bandwidth ISO mode
  - Supports 15 IN, 15 OUT endpoints (EPs), and one EP0 endpoint which is bidirectional
- The integrated USB PHY module:
  - A USB2 PHY connected to the core via internal UTMI+ port
- External interfaces (towards device boundary):
  - To USB Connector:
    - DP/DM - a bidirectional signal pair for HS, FS, LS mode operation
    - VBUS - an analog pin for monitoring the voltage on VBUS.
    - ID - an input signal for operating mode (Host/Device) determination.
  - To an external Charge Pump for VBUS 5V generation:
    - DRVVBUS - an active high output that controls an external 5V charge pump. The core uses this output to automatically ensure that VBUS has 5V supplied by the charge pump during Host mode operation.

- Internal interface (towards internal system):
  - An OCP slave interface for MMR transactions to/from the controller.
  - An OCP slave interface for MMR transactions to/from the PHY.
  - An AXI master interface for high-bandwidth DMA transactions.
  - Interrupt interface:
    - USB_MAINn_INT[3:0] - 4 programmable interrupts associated with DMA traffic
    - USB_MISCINT - single interrupt line for misc events

16.2.1 USB Clock and Reset Management

The USB2SS contains several functional clock domains: BUS, PHYMMR, and UTMI+ Interface.

Table 16-1 provides the details of the clock drivers and the control of the clocks.

Table 16-1. USB2SS Clock Sources and Clock Control

Clock Signal	Max Frequency	Reference / Source	Comments
ocp_clk XHCImaster/slave interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l3s_gclk From PRCM
phy_clk Phy slave interface clock	100 MHz	CORE_CLKOUTM4 / 4	pd_per_l4s_gclk From PRCM
suspend_clk Phy low power functional clock	125 MHz	CLK_M_OSC	pd_usb_otg_ssrefclk From PRCM
phy_other_refclk960m UTMI source clock	960 MHz	USB_PHYCLK	DCOCLKLDO from Per PLL
phy_other_trefclk Phy reference clock	50 MHz	CLK_M_OSC	
phy_other_sparein[0] Phy auto-resume logic wakeup clock	32 KHz	CLK32K_RTC	pd_wakeup_usbphy_32khz_gclk From PRCM

16.2.2 USB Pin List

The names of the pins used by the USB2SS with descriptions are shown in Table 16-2 and Table 16-3.

Table 16-2. USB Signal Pins Description

Pin Name	IOZP	IPD/IPU	Nominal Voltage	Description
USBn_DP	IOZ		3.3V	USB 2.0 and 1.1 specification-compliant signal pins. They are HS/FS/LS bidirectional differential data pins.
USBn_DM	IOZ		3.3V	

Table 16-3. USB Control, Configuration, and Monitor Signal Pins

Pin Name	IOZP	Nominal Voltage	Description
USBn_DRVVBUS	O		An active-high digital output signal for VBUS power supply. Used to enable an external charge pump to supply +5V power to the VBUS port of the device as well as the VBUS port of the USB receptacle, when appropriate per the USB standard. Output is 0 at reset.
USBn_VBUS	A	5.0V	An analog input for monitoring the voltage on VBUS.
USBn_ID	A		Used to determine the operational mode (Host/Peripheral) of the controller. When grounded, the controller will operate as a USB Host. When left floating, the controller will operate as a USB Peripheral. NOTE: This pin should never be connected to a voltage source.
USBn_CE	O	3.3V	An active high digital output for PHY charge enable.

16.3 Use Cases

This is a standard USB 2.0 module, and is optimized for following applications and systems:

- Portable electronic devices
- High-bandwidth applications

It supports all typical USB connections, and Table 16-4 shows some examples.

Table 16-4. Typical Use Cases In Terms of Connections

Connectors (Receptacle)	Signals to Use	SS	HS/FS	LS (Host only)	Comments
USB 2.0 Micro-AB	DP, DM, VBUS, ID	N	Y	Y	Support Host or Device operation, depending on state of the ID pin.
USB 2.0 Type-A	DP, DM, VBUS	N	Y	Y	Support HS/FS/LS Host
USB 2.0 Type-B	DP, DM, VBUS	N	Y	N	Only used for USB2.0 Device (no LS)

16.3.1 USB Operational Mode Determination

As the USB controller modules present in this device are DRD (Dual-Role Devices), they can support operation as either a USB Host or a USB Device. The operational mode determination is made based on the state of the USBn_ID pin; when this pin is grounded, the controller will operate as a USB Host, when this pin is left floating, the controller assumes the role of a USB Device. For implementations that do not require DRD functionality, the USBn_ID pin can either be left floating or can be grounded in the board design depending on the static role required. For implementations that do require DRD functionality, the USBn_ID pin should be connected directly to the corresponding ID pin on a USB Micro-AB socket. In doing so, the USBn_ID pin will be correctly terminated (open or grounded) depending on the cable attached and the controller will enter Host or Device mode accordingly. Refer to Section 16.3.2 for more details.

16.3.2 Typical Pin Connections of AM437x Device

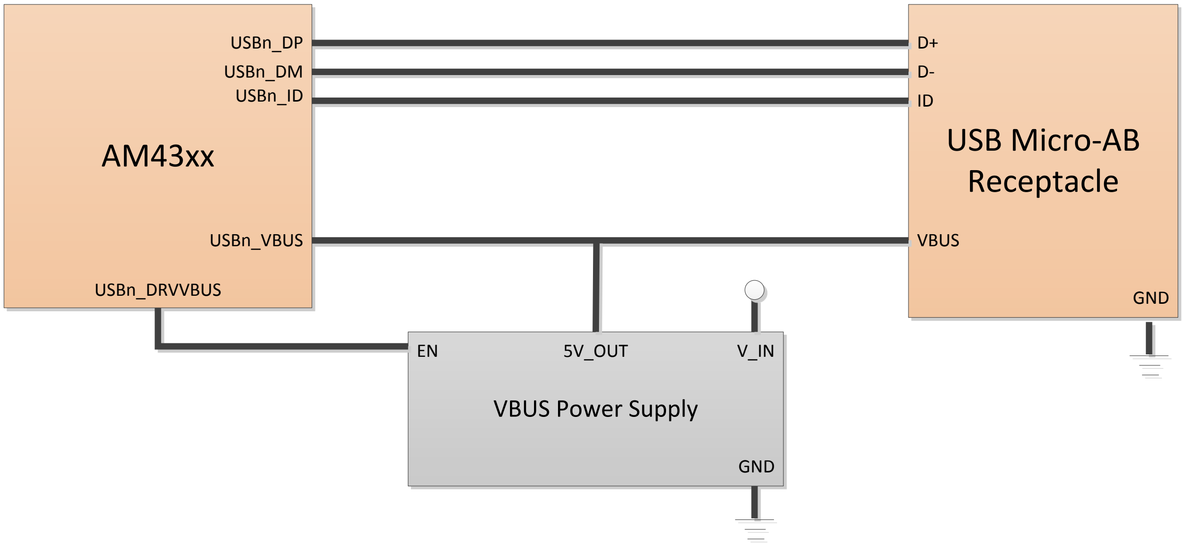

Figure 16-2. USB Dual-Role (Host or Device)

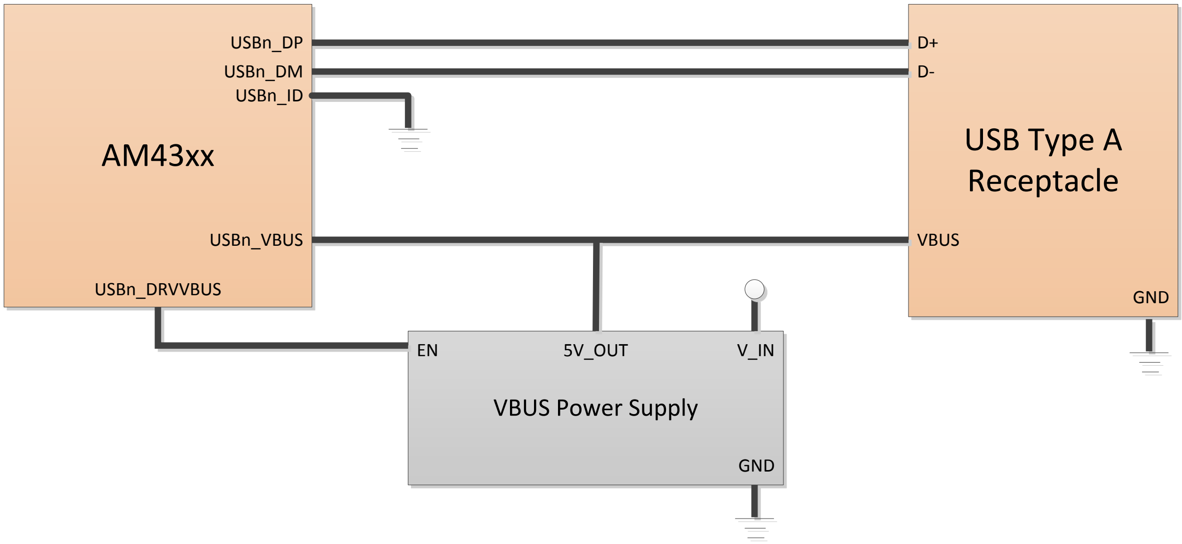

Figure 16-3. USB Host Only

Figure 16-4. USB Device Only

16.3.3 VBUS Voltage Sourcing Control

When either of the USB controllers assumes the role of a host, the controller is required to supply 5V to an attached device through its VBUS line. In order to achieve this task, the USB controller requires the use of external power logic (or a charge pump) capable of sourcing 5V power. The USB_DRVVBUS pin is used as a control signal to enable/disable this external power logic to either source or disable power on the VBUS line. The control on the USB_DRVVBUS is automatic and is handled by the USB controller. The control should be transparent to the user so long as the proper hardware connection and software initialization are in place. The USB controller drives the USB_DRVVBUS signal high when it assumes the role of a host while the controller is in session. When assuming the role of a device, the controller drives the USB_DRVVBUS signal low disabling the external charge pump/power logic; hence, no power is driven on the VBUS line (in this case, power is expected to be provided by the external host).

Note that both USB controllers are self-powered and the device does not rely on the voltage on the VBUS line sourced by an external host for controller operation when assuming the role of a device. The voltage present on the VBUS line is used to identify the presence of a Host. The USB PHY continually monitors the voltage on the VBUS and reports the status to USB controller.

16.3.4 Pull-up/Pull-down Resistors

As the USB controllers are dual role controllers, capable of assuming a role of a host or device, the required pull-up/pull-down resistors cannot exist external to the device. These pull-up/pulldown resistors exist internal to the device, within the PHY to be more specific, and are enabled or disabled based on the role the controller assumes allowing for dynamic hardware configuration. When assuming the role of a host, the data lines are pulled low by the PHY enabling the internal 15KΩ resistors. When assuming the role of a device the required 1.5KΩ pull-up resistor on the D+ line is enabled automatically to signify the USB capability to the external host as a FS device (HS operation is negotiated during reset bus condition).

16.3.5 Clock, PLL, and PHY Initialization

Prior to configuring the USB Module Registers, the USB Subsystem and PHY are required to be released from reset, relevant interconnects and clocks must be enabled and the PHY itself must be configured.

Chapter 17

SPRUHL7H–April 2014–Revised January 2018

Multimedia Card (MMC)

This chapter describes the MMC of the device.

Topic **Page**

17.1 Introduction

17.1.1 MMCSD Features

The general features of the MMCSD host controller IP are:

- Built-in 1024-byte buffer for read or write
- Two DMA channels, one interrupt line
- Clock support
  - 96-MHz functional clock source input
  - up to 384Mbit/sec (48MByte/sec) in MMC mode 8-bit data transfer
  - up to 192Mbit/sec (24MByte/sec) in High-Speed SD mode 4-bit data transfer
  - up to 24Mbit/sec (3MByte/sec) in Default SD mode 1-bit data transfer
- Support for SDA 3.0 Part A2 programming model
- Serial link supports full compliance with:
  - MMC command/response sets as defined in the MMC standard specification v4.3.
  - SD command/response sets as defined in the SD Physical Layer specification v2.00
  - SDIO command/response sets and interrupt/read-wait suspend-resume operations as defined in the SD part E1 specification v 2.00
  - SD Host Controller Standard Specification sets as defined in the SD card specification Part A2 v2.00

17.1.2 Unsupported MMCSD Features

The MMCSD module features not supported in this device are shown in Table 17-1.

Table 17-1. Unsupported MMCSD Features

Feature	Reason
MMC Out-of-band interrupts	MMC_OBI input tied low
Master DMA operation	Disabled through synthesis parameter
Card Supply Control (MMCSD(1-2))	Signal not pinned out
Dual Data Rate (DDR) mode	Timing not supported

17.2 Integration

This device contains three instances of the Multimedia Card (MMC), Secure Digital (SD), and Secure Digital I/O (SDIO) high speed interface module (MMCHS). The controller provides an interface to an MMC, SD memory card or SDIO card.

The application interface is responsible for managing transaction semantics; the MMC/SDIO host controller deals with MMC/SDIO protocol at transmission level, packing data, adding CRC, start/end bit and checking for syntactical correctness. Figure 17-1 through Figure 17-3 below show examples of systems using the MMCSD controller. Note that the power switch control is only available on the MMCSD0 interface.

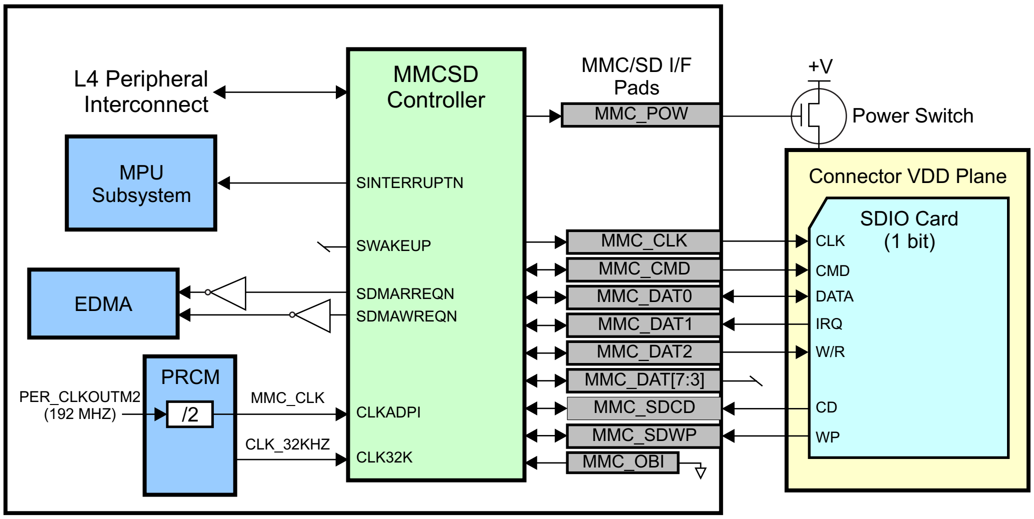

Figure 17-1. MMCSD Module SDIO Application

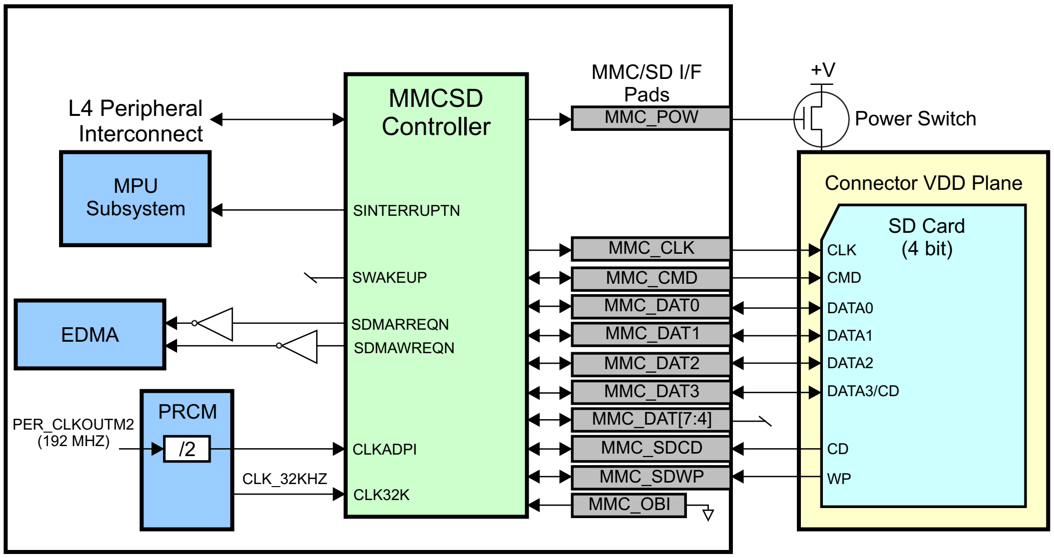

Figure 17-2. MMCSD (4-bit) Card Application

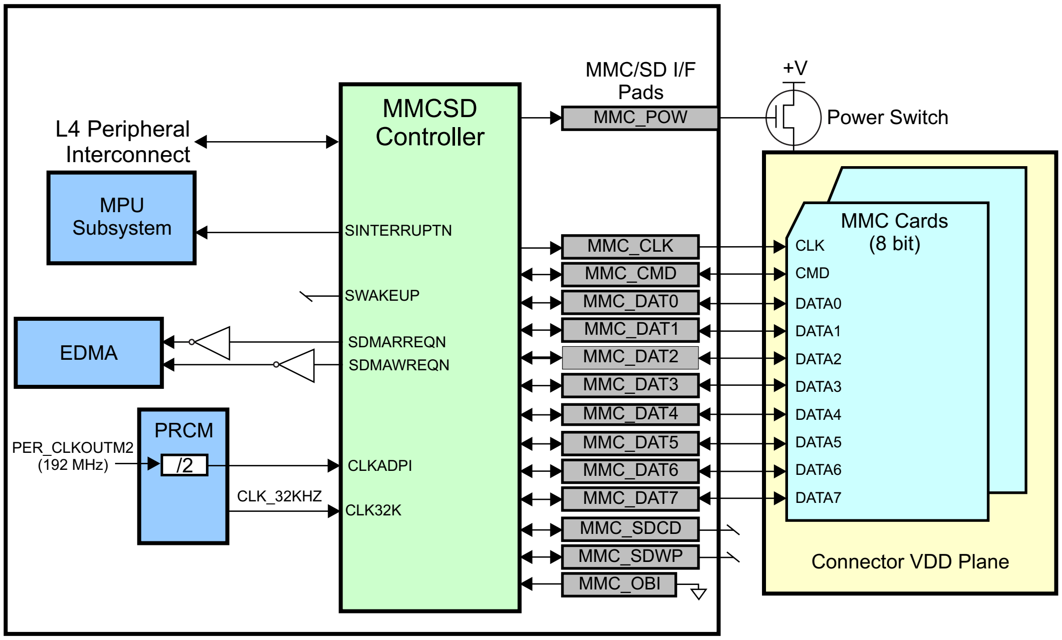

Figure 17-3. MMCSD Module MMC Application

17.2.1 MMCSD Connectivity Attributes

The general connectivity attributes for the three MMCSD modules are shown in Table 17-2.

Table 17-2. MMCSD Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK (OCP) PD_PER_MMC_FCLK (Func) CLK_32KHZ (Debounce)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	1 interrupt per instance to MPU Subsystem (MMCSDxINT)
DMA Requests	2 DMA requests per instance to EDMA (SDTXEVTx, SDRXEVTx) (Active low, need to be inverted in glue logic)
Physical Address	L4 Peripheral slave port

17.2.2 MMCSD Clock and Reset Management

The MMCSD controller has separate bus interface and functional clocks. The debounce clock is created by dividing the 48-MHz (24 MHz @ OPP50) clock in the PRCM by two and then dividing the resulting 24-MHz (12 MHz @ OPP50) clock by a fixed 732.4219 (366.2109 @ OPP50) in the Control Module to get a 32-kHz clock. This clock is fed back into the PRCM for clock gating. (See the CTRL_CLK32KDIVRATIO register in Chapter 7, *Control Module*, for more details).

Table 17-3. MMCSD Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
CLK Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk from PRCM
CLKADPI Functional clock	48 MHz	PER_CLKOUTM2 / 4	pd_per_mmc_fclk from PRCM
CLK32 Input de-bounce clock	32.768 KHz	CLK_24 / 732.4219	clk_32KHz from PRCM

17.2.3 MMCSD Pin List

The MMCSD interface pins are summarized in Table 17-4.

Table 17-4. MMCSD Pin List

Pin	Type	Description
MMC*x*_CLK	I/O(1)	MMC/SD serial clock output
MMC*x*_CMD	I/O	MMC/SD command signal
MMC*x*_DAT0	I/O	MMC/SD data signal
MMC*x*_DAT1	I/O	MMC/SD data signal, SDIO interrupt input
MMC*x*_DAT2	I/O	MMC/SD data signal, SDIO read wait output
MMC*x*_DAT[7:3]	I/O	MMC/SD data signals
MMC*x*_POW	O	MMC/SD power supply control (MMCSD0 only)
MMC*x*_SDCD	I	SD card detect (from connector)
MMC*x*_SDWP	I	SD write protect (from connector)
MMC*x*_OBI	I	MMC out of band interrupt

(1) These signals are also used as inputs to re-time or sync data. The associated CONF_<module>_pin_RXACTIVE bit for these signals must be set to 1 to enable the inputs back to the module. It is also recommended to place a 33-ohm resistor in series (close to the processor) on each of these signals to avoid signal reflections.

The direction of the data lines depends on the selected data transfer mode as summarized in Table 17-5.

Table 17-5. DAT Line Direction for Data Transfer Modes

	MMC/SD 1-bit mode	MMC/SD 4-bit mode	MMC/SD 8-bit mode	SDIO 1-bit mode	SDIO 4-bit mode
DAT[0]	I/O	I/O	I/O	I/O	I/O
DAT[1]	I(1)	I/O	I/O	I(2)	I/O or I(2)
DAT[2]	I(1)	I/O	I/O	I/O(3)	I/O or O(3)
DAT[3]	I(1)	I/O	I/O	I(1)	I/O
DAT[4]	I(1)	I(1)	I/O	I(1)	I(1)
DAT[5]	I(1)	I(1)	I/O	I(1)	I(1)
DAT[6]	I(1)	I(1)	I/O	I(1)	I(1)
DAT[7]	I(1)	I(1)	I/O	I(1)	I(1)

(1) Hi-Z state to avoid bus conflict.
(2) To support incoming interrupt from the SDIO card.
(3) To support read wait to the SDIO card. By default it is Input, Output only in read wait period.

The direction of the MMCSD data buffers are controlled by ADPDATDIROQ signals. ADPDATDIROQ[i] = 1 sets the corresponding DAT signal(s) in read position (input) and ADPDATDIROQ[i] = 0 sets the corresponding DAT signal(s) in write position (output). Additionally, the ADPDATDIRLS signals are provided (with opposite polarity) to control the direction of external level shifters. The value of these control signals for the various data modes are summarized in Table 17-6.

Table 17-6. ADPDATDIROQ and ADPDATDIRLS Signal States

	MMC/SD 1-bit mode	**MMC/SD 4-bit mode**	**MMC/SD 8-bit mode**	**SDIO 1-bit mode**	**SDIO 4-bit mode**
DAT[0]	ADPDATDIRLS[0] = 0 / 1 ADPDATDIROQ[0] = 1 / 0	ADPDATDIRLS[0] = 0 / 1 ADPDATDIROQ[0] = 1 / 0	ADPDATDIRLS[0] = 0 / 1 ADPDATDIROQ[0] = 1 / 0	ADPDATDIRLS[0] = 0 / 1	ADPDATDIRLS[0] = 0 / 1 ADPDATDIROQ[0] = 1 / 0
DAT[2]	ADPDATDIRLS[2] = 0 ADPDATDIROQ[2] = 1	ADPDATDIRLS[2] = 0 / 1 ADPDATDIROQ[2] = 1 / 0	ADPDATDIRLS[2] = 0 / 1 ADPDATDIROQ[2] = 1 / 0	ADPDATDIRLS[2] = 0 / 1 ADPDATDIROQ[2] = 1 / 0	ADPDATDIRLS[2] = 0 / 1 ADPDATDIROQ[2] = 1 / 0
DAT[1]	ADPDATDIRLS[1] = 0 ADPDATDIROQ[1] = 1	ADPDATDIRLS[1] = 0 / 1 ADPDATDIROQ[1] = 1 / 0	ADPDATDIRLS[1] = 0 / 1 ADPDATDIROQ[1] = 1 / 0	ADPDATDIRLS[1] = 0 ADPDATDIROQ[1] = 1	ADPDATDIRLS[1] = 0 / 1 ADPDATDIROQ[1] = 1 / 0
DAT[3]					
DAT[4]	ADPDATDIRLS[3] = 0 ADPDATDIROQ[3] = 1	ADPDATDIRLS[3] = 0 ADPDATDIROQ[3] = 1	ADPDATDIRLS[3] = 0 / 1 ADPDATDIROQ[3] = 1 / 0	ADPDATDIRLS[3] = 0 ADPDATDIROQ[3] = 1	ADPDATDIRLS[3] = 0 ADPDATDIROQ[3] = 1
DAT[5]					
DAT[6]					
DAT[7]					

ADPDATIRLSx = 0 for input and 1 for output — these signals are not pinned out on this device.

ADPDATIROQx = 1 for output and 1 for input.

Grayed cells indicate that the data line is not used in the selected transfer mode.

17.3 Functional Description

One MMC/SD/SDIO host controller can support one MMC memory card, one SD card, or one SDIO card.

Other combinations (for example, two SD cards, one MMC card, and one SD card) are not supported through a single controller.

17.3.1 MMC/SD/SDIO Functional Modes

17.3.1.1 MMC/SD/SDIO Connected to an MMC, an SD Card, or an SDIO Card

Figure 17-4 shows the MMC/SD/SDIO1 and MMC/SD/SDIO2 host controllers connected to an MMC, an SD, or an SDIO card and its related external connections.

Figure 17-4. MMC/SD1/2 Connectivity to an MMC/SD Card

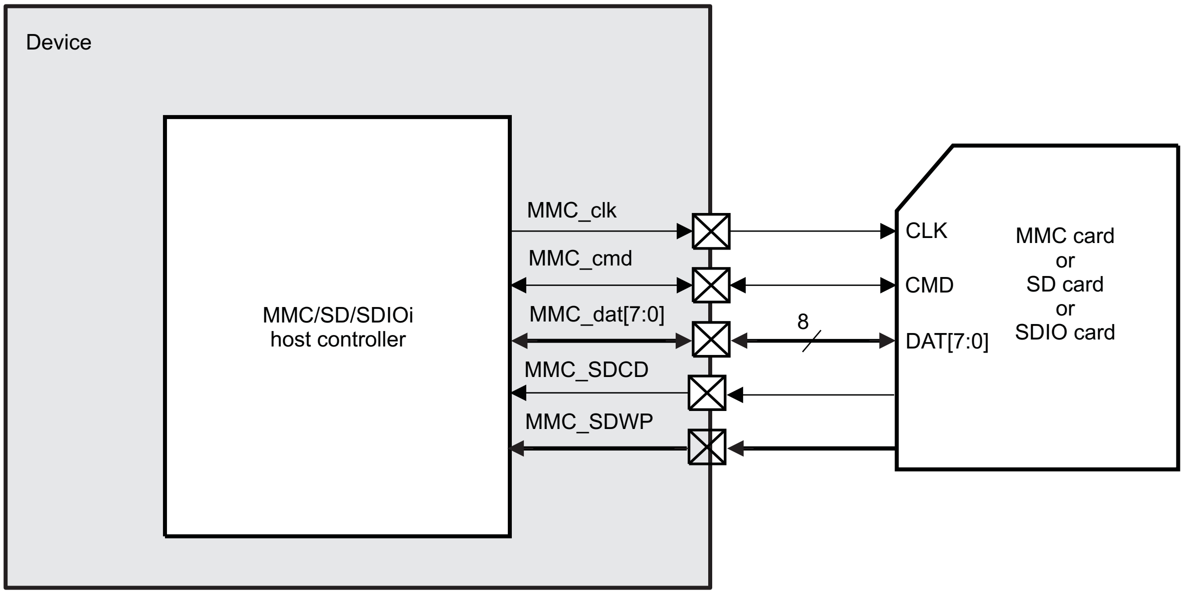

Figure 17-5. MMC/SD0 Connectivity to an MMC/SD Card

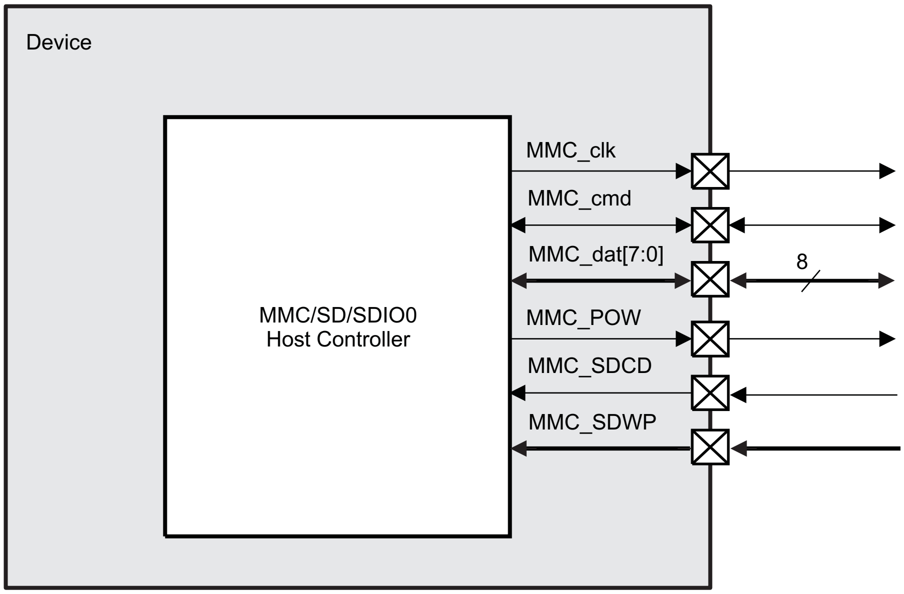

Figure 17-5 shows the MMC/SD/SDIO0 host controller connected to an MMC, SD, or SDIO card and its related external connections. Note that MMC/SD/SDIO0 uses the same signals as MMC/SD/SDIO1 and 2 but adds MMC_POW.

The following MMC/SD/SDIO controller pins are used

- **MMC_CMD** This pin is used for two-way communication between the connected card and the MMC/SD/SDIO controller. The MMC/SD/SDIO controller transmits commands to the card and the memory card drives responses to the commands on this pin.
- **MMC_DAT7-0** Depending on which type of card you are using, you may need to connect 1, 4, or 8 data lines. The number of DAT pins (the data bus width) is set by the Data Transfer Width (DTW) bit in the MMC control register (SD_HCTL). For more information, see Section 17.5.1, *MMCSD Registers*.
- **MMC_CLK** This pin provides the clock to the memory card from the MMC/SD controller.
- **MMC_POW** Used for MMC/SD card's cards on/off power supply control. When high, denotes power-on condition.
- **MMC_SDCD** This input pin serves as the MMC/SD/SDIO card detect. This signal is received from a mechanical switch on the slot.
- **MMC_SDWP** This input pin is used for the SD/SDIO card's write protect. This signal is received from a mechanical protect switch on the slot (system dependant). Applicable only for SD and SDIO cards that have a mechanical sliding tablet on the side of the card.

  Note: The MMC_CLK pin functions as an output but must be configured as an I/O to internally loopback the clock to time the inputs.

Table 17-7 provides a summary of these pins.

Table 17-7. MMC/SD/SDIO Controller Pins and Descriptions

Pin	Type	1-Bit Mode	4-Bit Mode	8-Bit Mode	Reset Value
MMC_CLK[1]	O	Clock Line	Clock Line	Clock Line	High impedance
MMC_CMD	I/O	Command Line	Command Line	Command Line	High impedance
MMC_DAT0	I/O	Data Line 0	Data Line 0	Data Line 0	0
MMC_DAT1	I/O	(not used)	Data Line 1	Data Line 1	0
MMC_DAT2	I/O	(not used)	Data Line 2	Data Line 2	0
MMC_DAT3	I/O	(not used)	Data Line 3	Data Line 3	0
MMC_DAT4	I/O	(not used)	(not used)	Data Line 4	0
MMC_DAT5	I/O	(not used)	(not used)	Data Line 5	0
MMC_DAT6	I/O	(not used)	(not used)	Data Line 6	0
MMC_DAT7	I/O	(not used)	(not used)	Data Line 7	0

(1) The MMC_CLK pin functions as an output but must be configured as an I/O to internally loopback the clock to time the inputs.

17.3.1.2 Protocol and Data Format

The bus protocol between the MMC/SD/SDIO host controller and the card is message-based. Each message is represented by one of the following parts:

Command: A command starts an operation. The command is transferred serially from the \MMC/SD/SDIO host controller to the card on the mmc_cmd line.

Response: A response is an answer to a command. The response is sent from the card to the MMC/SD/SDIO host controller. It is transferred serially on the mmc_cmd line.

Data: Data are transferred from the MMC/SD/SDIO host controller to the card or from a card to the MMC/SD/SDIO host controller using the DATA lines.

Busy: The mmc_dat0 signal is maintained low by the card as far as it is programming the data received.

CRC status: CRC result is sent by the card through the mmc_dat0 line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on mmc_dat0. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on mmc_dat0 and starts the data programming procedure.

17.3.1.2.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented). See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, and the *SDIO Card Specification, Part E1* for details about commands and programming sequences supported by the MMC, SD, and SDIO cards.

CAUTION

Stream commands are supported only by MMC cards.

Figure 17-6 and Figure 17-7 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the mmc_cmd line.

Figure 17-6. Sequential Read Operation (MMC Cards Only)

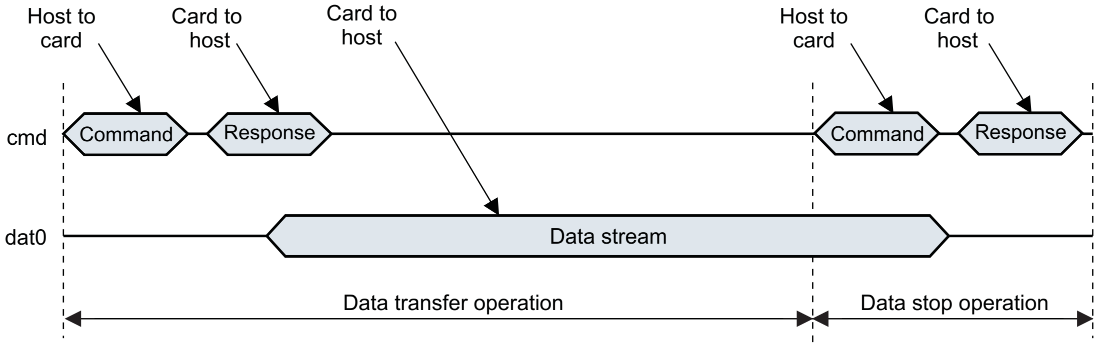

Figure 17-7. Sequential Write Operation (MMC Cards Only)

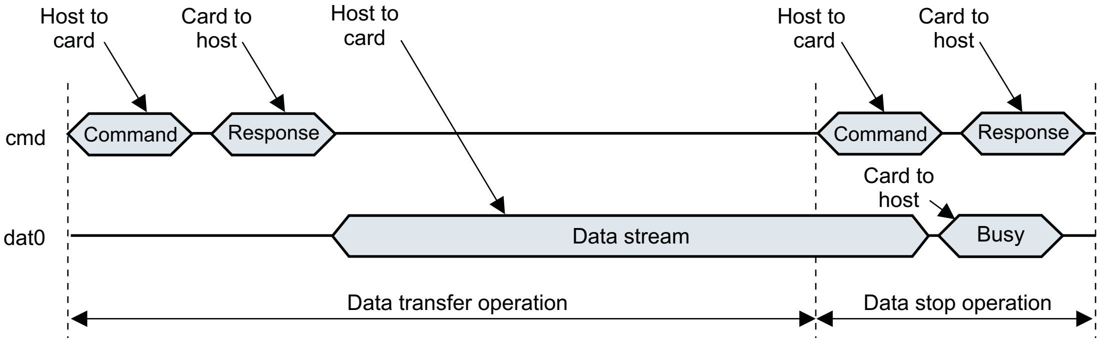

Figure 17-8 and Figure 17-9 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the mmc_cmd line. These operations are available for all kinds of cards.

Figure 17-8. Multiple Block Read Operation (MMC Cards Only)

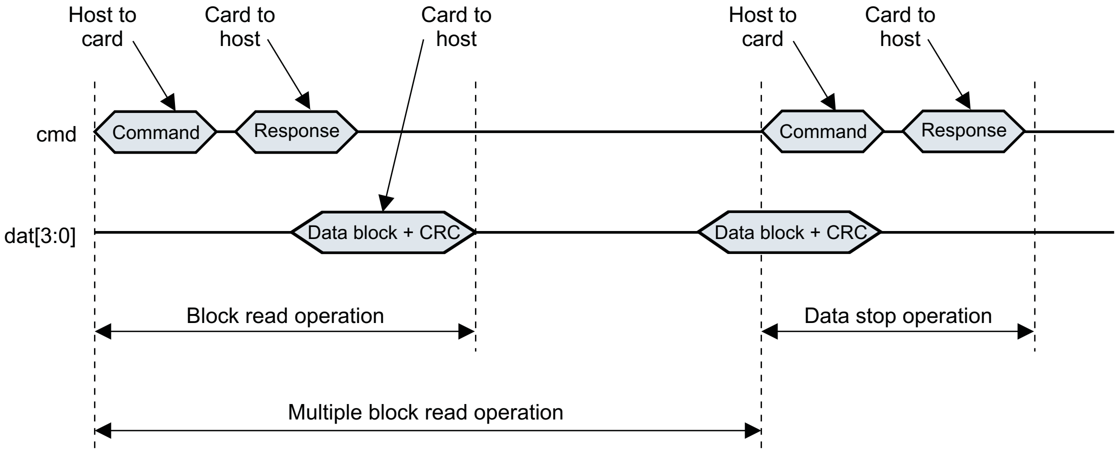

Figure 17-9. Multiple Block Write Operation (MMC Cards Only)

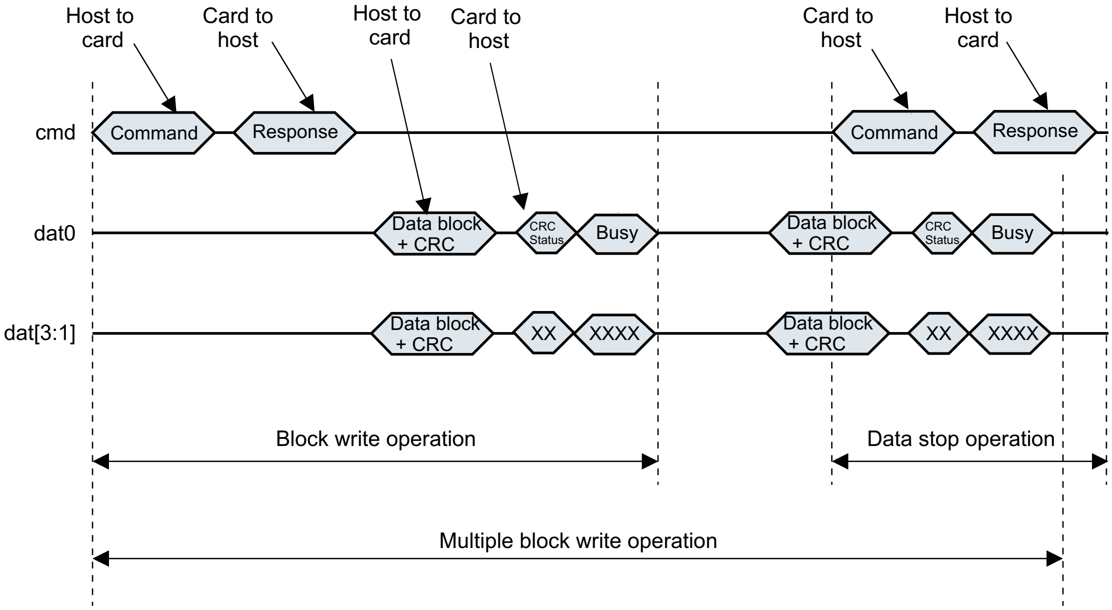


NOTE:

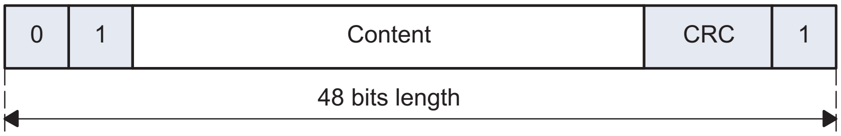
1. The card busy signal is not always generated by the card; the previous examples show a particular case.
2. It is the software's responsibility to do a software reset after a data timeout to ensure that mmc_clk is stopped. The software reset is done by setting bit 26 in the SD_SYSCTL register to 1.
3. For multiblock transfer, and especially for MMC cards, you can abort a transfer without using a stop command. Use a CMD23 before a data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (provided the MMC card supports this feature).

17.3.1.2.2 Data Format

Coding Scheme for Command Token

Command packets always start with 0 and end with 1. The second bit is a transmitter bit1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see Figure 17-10).

Figure 17-10. Command Token Format



Coding Scheme for Response Token

Response packets always start with 0 and end with a 1. The second bit is a transmitter bit0 for a card response. The content is different for each type of response (R1, R2, R3, R4, R5, and R6) and the content is protected by 7-bit CRC checksum. Depending on the type of commands sent to the card, the SD_CMD register must be configured differently to avoid false CRC or index errors to be flagged on command response (see Table 17-8). For more details about response types, see the *Multimedia Card System Specification*, the *SD Memory Card Specification*, or the *SDIO Card Specification*.

Table 17-8. Response Type Summary(1)

Response Type SD_CMD[17:16] RSP_TYPE	Index Check Enable SD_CMD[20] CICE	CRC Check Enable SD_CMD[19] CCCE	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5 (R7 for SD cards)
11	1	1	R1b, R5b

(1) The MMC/SD/SDIO host controller assumes that both clocks may be switched off, whatever the value set in the SD_SYSCONFIG[9:8] CLOCKACTIVITY bit.

Figure 17-11 and Figure 17-12 depict the 48-bit and 136-bit response packets.

Figure 17-11. 48-Bit Response Packet (R1, R3, R4, R5, R6)

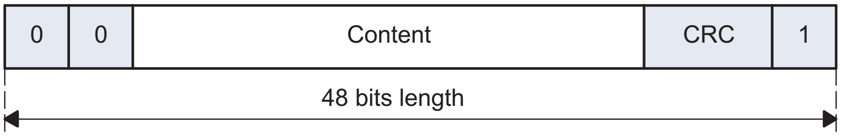


Figure 17-12. 136-Bit Response Packet (R2)

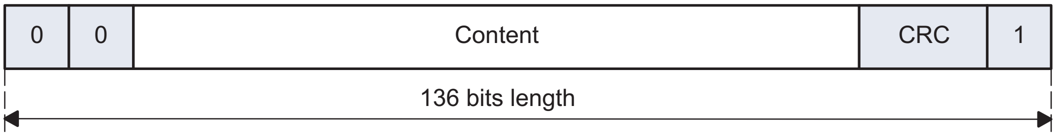

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see Figure 17-13, Figure 17-14, Figure 17-15, and Figure 17-16).

Figure 17-13. Data Packet for Sequential Transfer (1-Bit)

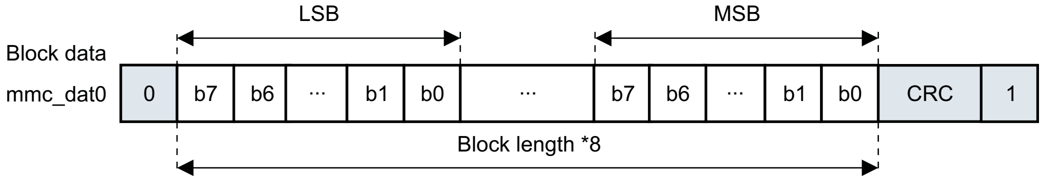

Figure 17-15. Data Packet for Block Transfer (4-Bit)

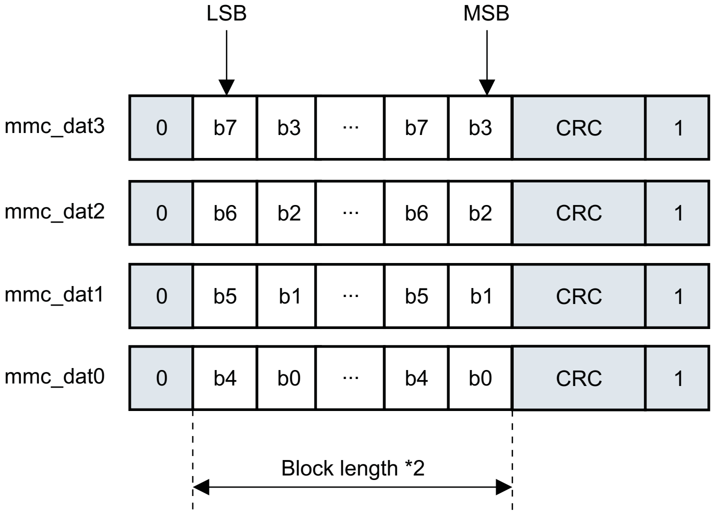

Figure 17-16. Data Packet for Block Transfer (8-Bit)

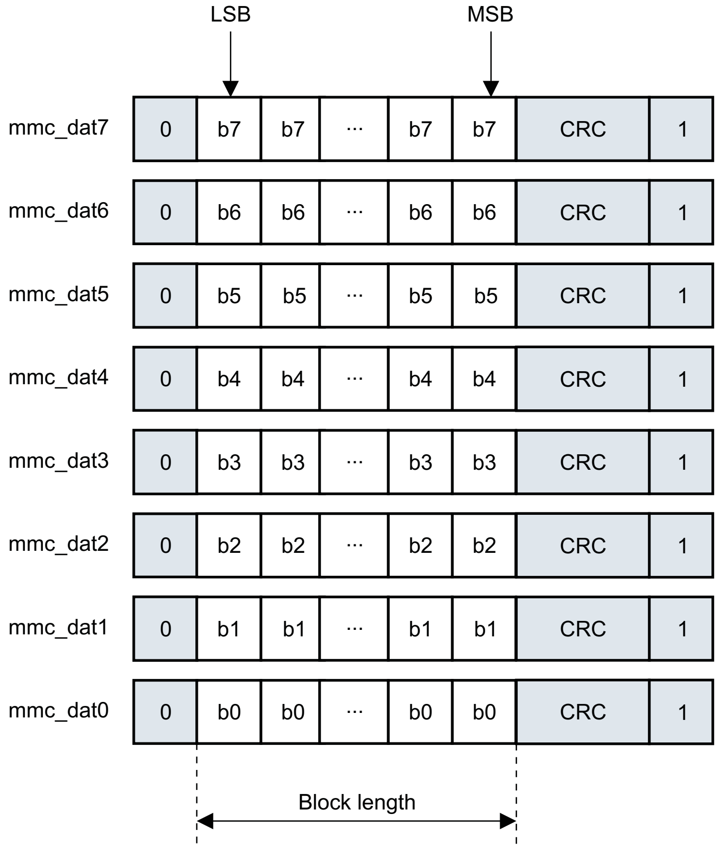


17.3.2 Resets

17.3.2.1 Hardware Reset

The module is reinitialized by the hardware.

The SD_SYSSTS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a hardware reset.

This hardware reset signal has a global reset action on the module. All configuration registers and all state machines are reset in all clock domains.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

17.3.2.2 Software Reset

The module is reinitialized by software through the SD_SYSCONFIG[1] SOFTRESET bit. This bit has the same action on the module logic as the hardware signal except for:

- Debounce logic
- SD_PSTATE, SD_CAPA, and SD_CUR_CAPA registers (see corresponding register descriptions)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by the hardware. The SD_SYSCTL[24] SRA bit has the same action as the SOFTRESET bit on the design.

The SD_SYSSTS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a software reset.

Moreover, two partial software reset bits are provided:

- SD_SYSCTL[26] SRD bit
- SD_SYSCTL[25] SRC bit

These two reset bits are useful to reinitialize data or command processes respectively in case of line conflict. When set to 1, a reset process is automatically released when the reset completes:

- The SD_SYSCTL[26] SRD bit resets all finite state-machines and status management that handle data transfers on both the interface and functional side.
- The SD_SYSCTL[25] SRC bit resets all finite state-machines and status management that handle command transfers on both the interface and functional side.

NOTE: If **any** of the clock inputs are not present for the MMC/SD/SDIO peripheral, the software reset will not complete.

17.3.3 Power Management

The MMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The MMC/SD/SDIO host controller is compliant with the PRCM module handshake protocol. When the MMC/SD/SDIO power domain is off, the only way to wake up the power domain and different MMC/SD/SDIO clocks is to monitor the mmc_dat1 input pin state via a different GPIO line for each MMC/SD/SDIO interface.

17.3.3.1 Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The SD_SYSCONFIG[0] AUTOIDLE bit is set to 1.
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L3 (or L4) interconnect.
- A wake-up event occurs (an interrupt from a SDIO card).
- A transaction on the MMC/SD/SDIO interface starts.

Then the MMC/SD/SDIO host controller enters in low-power state even if SD_SYSCONFIG[0] AUTOIDLE is cleared to 0. The functional clock is internally switched off and only interconnect read and write accesses are allowed.

17.3.3.2 Idle Mode

The clocks provided to MMC/SD/SDIO are switched off upon a PRCM module request. They are switched back upon module request. The MMC/SD/SDIO host controller complies with the PRCM module handshaking protocol:

- Idle request from the system power manager
- Idle acknowledgment from the MMC/SD/SDIO host controller

The idle acknowledgment varies according to the SD_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0: Force-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request unconditionally.
- 1h: No-idle mode. The MMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 2h: Smart-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.

- 3h: Reserved.

During the smart-idle mode period, the MMC/SD/SDIO host controller acknowledges that the OCP and Functional clocks may be switched off whatever the value set in the SD_SYSCONFIG[9:8] CLOCKACTIVITY field.

17.3.3.3 Transition from Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the SD_SYSCONFIG[4:3] SIDLEMODE bit field is set to 2h or 3h. The MMC/SD/SDIO host controller goes into idle mode when the PRCM issues an idle request, according to its internal activity. The MMC/SD/SDIO host controller acknowledges the idle request from the PRCM after ensuring the following:

- The current multi/single-block transfer is completed.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on the SD_dat1 signal.

As long as the MMC/SD/SDIO controller does not acknowledge the idle request, if an event occurs, the MMC/SD/SDIO host controller can still generate an interrupt or a DMA request. In this case, the module ignores the idle request from the PRCM.

As soon as the MMC/SD/SDIO controller acknowledges the idle request from the PRCM:

- If Smart-Idle mode the module does not assert any new interrupt or DMA request

17.3.3.4 Transition from Smart-Idle Mode to Normal Mode

The MMC/SD/SDIO host controller detects the end of the idle period when the PRCM deasserts the idle request. For the wake-up event, there is a corresponding interrupt status in the SD_STAT register. The MMC/SD/SDIO host controller operates the conversion between wake-up and interrupt (or DMA request) upon exit from smart-idle mode if the associated enable bit is set in the SD_ISE register.

Interrupts and wake-up events have independent enable/disable controls, accessible through the SD_HCTL and SD_ISE registers. The overall consistency must be ensured by software.

The interrupt status register SD_STAT is updated with the event that caused the wake-up in the CIRQ bit when the SD_IE[8] CIRQ_ENABLE associated bit is enabled. Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The SD_STAT register is updated and the status of the interrupt signal changes.)

When the idle request from the PRCM is deasserted, the module switches back to normal mode. The module is fully operational.

17.3.3.5 Force-Idle Mode

Force-idle mode is enabled when the SD_SYSCONFIG[4:3] SIDLEMODE bit field is cleared to 0. Force-idle mode is an idle mode where the MMC/SD/SDIO host controller responds unconditionally to the idle request from the PRCM. Moreover, in this mode, the MMC/SD/SDIO host controller unconditionally deasserts interrupts and DMA request lines are asserted.

The transition from normal mode to force-idle mode does not affect the bits of the SD_STAT register. In force-idle mode, the interrupt and DMA request lines are deasserted. Interface Clock (OCP) and functional clock (CLKADPI) can be switched off.

CAUTION

In Force-idle mode, an idle request from the PRCM during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the OCP clock is alive.

The module exits the force-idle mode when the PRCM deasserts the idle request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

17.3.3.6 Local Power Management

Table 17-9 describes power-management features available for the MMC/SD/SDIO modules.

Table 17-9. Local Power Management Features

Feature	Registers	Description
Clock Auto Gating	SD_SYSCONFIG AUTOIDLE bit	This bit allows a local power optimization inside module, by gating the OCP clock upon the interface activity or gating the CLKADPI clock upon the internal activity.
Slave Idle Modes	SD_SYSCONFIG SIDLEMODE bit	Force-idle, No-idle, and Smart-idle modes
Clock Activity	SD_SYSCONFIG CLOCKACTIVITY bit	Please see Table 17-10 for configuration details.
Global Wake-Up Enable	SD_SYSCONFIG ENAWAKEUP bit	This bit enables the wake-up feature at module level.
Wake-Up Sources Enable	SD_HCTL register	This register holds one active high enable bit per event source able to generate wake-up signal.

Table 17-10. Clock Activity Settings

CLOCKACTIVITY Values	Clock State When Module is in IDLE State		Features Available when Module is in IDLE State	Wake-Up Events
	OCP Clock	CLKADPI		
00	OFF	OFF	None	Card Interrupt
10	OFF	ON	None	
01	ON	OFF	None	
11	ON	ON	All	

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY and MMC clock PRCM control bits.

17.3.4 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the SD_STAT register; it indicates which service is required.
- The interrupt status enable bits of the SD_IE register enable/disable the automatic update of the SD_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the SD_ISE register enable/disable the transmission of an interrupt request on the interrupt line MMC_IRQ (from the MMC/SD/SDIO host controller to the MPU subsystem interrupt controller) on an event-by-event basis.

If an interrupt status is disabled in the SD_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the SD_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 1 (the MMC/SD/SDIO host controller updates the status bit) in the SD_STAT register. If later a mask is applied on the interrupt in the SD_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the SD_STAT register and the corresponding mask is removed from the SD_ISE register, the interrupt status is not asserted again in the SD_STAT register and the MMC/SD/SDIOi host controller does not transmit an interrupt request.

CAUTION

If the buffer write ready interrupt (BWR) or the buffer read ready only interrupt (BRR) are not serviced and are cleared in the SD_STAT register, and the corresponding mask is removed, then the MMC/SD/SDIOi host controller will wait for the service of the interrupt without updating the status SD_STAT or transmitting an interrupt request.

Table 17-11 lists the event flags, and their mask, that can cause module interrupts.

Table 17-11. Events

Event Flag	Event Mask	Map To	Description
SD_STAT[29] BADA	SD_IE[29] BADA_ENABLE	MMC_IRQ	Bad Access to Data space. This bit is set automatically to indicate a bad access to buffer when not allowed. This bit is set during a read access to the data register (SD_DATA) while buffer reads are not allowed (SD_PSTATE[11] BRE=0). This bit is set during a write access to the data register (SD_DATA) while buffer writes are not allowed (SD_STATE[10] BWE=0)
SD_STAT[28] CERR	SD_IE[28] CERR_ENABLE	MMC_IRQ	Card Error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E(error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response errors SD_CSRE is set. There is not card detection for auto CMD12 command.
SD_STAT[25] ADMAE	SD_IE[25] ADMAE_ENABLE	MMC_IRQ	ADMA error. This bit is set when the host controller detects errors during ADMA based data transfer. The stat of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the host controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state.
SD_STAT[24] ACE	SD_IE[24] ACE_ENABLE	MMC_IRQ	Auto CMD12 error. This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1
SD_STAT[22] DEB	SD_IE[22] DEB_ENABLE	MMC_IRQ	Data End Bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on DAT line or at the end position of the CRC status in write mode.

Table 17-11. Events (continued)

Event Flag	Event Mask	Map To	Description
SD_STAT[21] DCRC	SD_IE[21] DCRC_ENABLE	MMC_IRQ	Data CRC error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command.
SD_STAT[20] DTO	SD_IE[20] DTO_ENABLE	MMC_IRQ	Data Timeout error. This bit is set automatically according to the following conditions: A) busy timeout for R1b, R5b response. B) busy timeout after write CRC status. C) write CRC status timeout, or D) read data timeout.
SD_STAT[19] CIE	SD_IE[19] CIE_ENABLE	MMC_IRQ	Command Index Error. This bit is set automatically when response index differs from corresponding command index previously emitted. The check is enabled through SD_CMD[20] CICE bit.
SD_STAT[18] CEB	SD_IE[18] CEB_ENABLE	MMC_IRQ	Command End Bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.
SD_STAT[17] CCRC	SD_IE[17] CCRC_ENABLE	MMC_IRQ	Command CRC error. This bit is set automatically when there is a CRC7 error in the command response. CRC check is enabled through the SD_CMD[19] CCCE bit.
SD_STAT[16] CTO	SD_IE[16] CTO_ENABLE	MMC_IRQ	Command Timeout error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands the reply within 5 clock cycles, the timeout is still detected at 64 clock cycles.
SD_STAT[15] ERRI	SD_IE[15] ERRI_ENABLE	MMC_IRQ	Error Interrupt. If any of the bits in the Error Interrupt Status register (SD_STAT[24:15]) are set, the this bit is set to 1.
SD_STAT[10] BSR	SD_IE[10] BSR_ENABLE	MMC_IRQ	Boot Status Received interrupt. This bit is set automatically when SD_CON[18] BOOT_CF0 is set to 1 or 2h and boot status is received on the dat0 line. This interrupt is only used for MMC cards.
SD_STAT[8] CIRQ	SD_IE[8] CIRQ_ENABLE	MMC_IRQ	Card Interrupt. This bit is only used for SD, SDIO, and CE-ATA cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wake-up). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drive CMD line to zero during one cycle after data transmission end.
SD_STAT[5] BRR	SD_IE[5] BRR_ENABLE	MMC_IRQ	Buffer Read ready. This bit is set automatically during a read operation to the card when one block specified by SD_BLK[10:0] BLEN is completely written in the buffer. It indicates that the memory card has filled out the buffer and the local host needs to empty the buffer by reading it.
SD_STAT[4] BWR	SD_IE[4] BWR_ENABLE	MMC_IRQ	Buffer Write ready. This bit is automatically set during a write operation to the card when the host can write a complete block as specified by SD_BLK[10:0] BLEN. It indicates that the memory card has emptied one block from the bugger and the local host is able to write one block of data into the buffer.
SD_STAT[3] DMA	SD_IE[3] DMA_ENABLE	MMC_IRQ	DMA interrupt. This status is set when an interrupt is required in the ADMA instruction and after the data transfer is complete.
SD_STAT[2] BGE	SD_IE[2] BGE_ENABLE	MMC_IRQ	Block Gap event. When a stop at block gap is requested (SD_HCTL[16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.
SD_STAT[1] TC	SD_IE[1] TC_ENABLE	MMC_IRQ	Transfer completed. This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap requested (SD_HCTL[16 SBGR). In read mode this bit is automatically set on completion of a read transfer (SD_PSTATE[9] RTA). In write mode, this bit is automatically set on completion of the DAT line use (SD_PSTATE[2] DLA).
SD_STAT[0] CC	SD_IE[0] CC_ENABLE	MMC_IRQ	Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (SD_PSTATE[0] CMDI). If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (SD_STAT[16] CTO) has higher priority than command complete (SD_STAT[0] CC). If a response is expected but none is received, the a Command Timeout error is detected and signaled instead of the Command Complete interrupt.

17.3.4.1 Interrupt-Driven Operation

An interrupt enable bit must be set in the SD_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

- Read the SD_STAT register to identify which event occurred.
- Write 1 into the corresponding bit of the SD_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this would return 0).

NOTE: In the SD_STAT register, Card Interrupt (CIRQ) and Error Interrupt (ERRI) bits cannot be cleared.

The SD_STAT[8] CIRQ status bit must be masked by disabling the SD_IE[8] CIRQ_ENABLE bit (cleared to 0), then the interrupt routine must clear SDIO interrupt source in SDIO card common control register (CCCR).

The SD_STAT[15] ERRI bit is automatically cleared when all status bits in SD_STAT[31:16] are cleared.

17.3.4.2 Polling

When the interrupt capability of an event is disabled in the SD_ISE register, the interrupt line is not asserted:

- Software can poll the status bit in the SD_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the SD_STAT register clears the interrupt status and does not affect the interrupt line state.

NOTE: Please see the note in Section 17.3.4.1 concerning CIRQ and ERRI bits clearing.

17.3.5 DMA Modes

The device supports DMA slave mode only. In this case, the controller is slave on DMA transaction managed by two separated requests (SDMAWREQN and SDMARREQN)

17.3.5.1 DMA Slave Mode Operations

The MMC/SD/SDIO controller can be interfaced with a DMA controller. At system level, the advantage is to discharge the local host (LH) of the data transfers. The module does not support wide DMA access (above 1024 bytes) for SD cards as specified in the *SD Card Specification*and *SD Host Controller Standard Specification*.

The DMA request is issued if the following conditions are met:

- The SD_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the SD_cmd line.
- There is enough space in the buffer of the MMC/SD/SDIO controller to write an entire block (BLEN writes).

17.3.5.1.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal SDMARREQN is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the SD_BLK[10:0] BLEN field.

The SDMARREQN signal is deasserted to its inactive level when the sDMA has read one single word from the buffer. Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

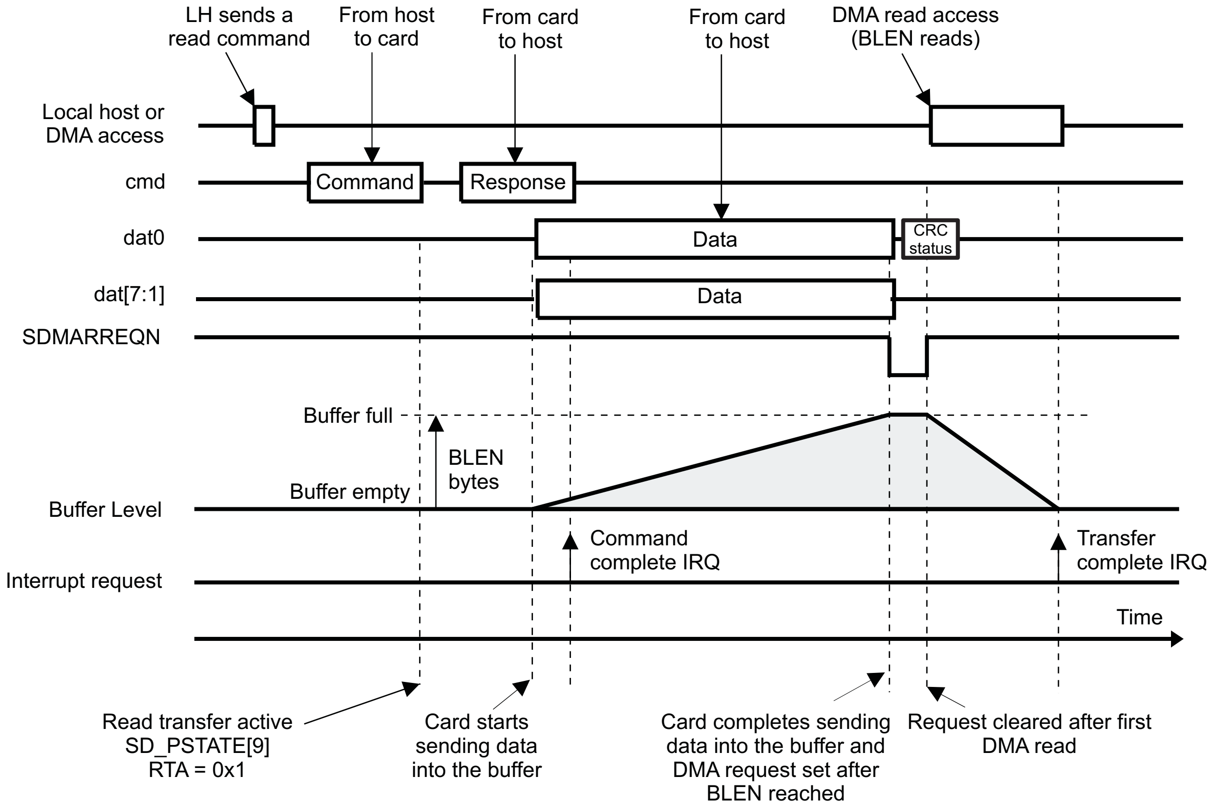
New DMA requests are internally masked if the sDMA has not read exactly BLEN bytes and a new complete block is not ready. As DMA accesses are in 32-bit, then the number of sDMA read is Integer(BLEN/4)+1.

The receive buffer never overflows. In multiple block transfers for block size above 512 bytes, when the buffer gets full, the MMC_CLK clock signal (provided to the card) is momentarily stopped until the sDMA or the MPU performs a read access, which reads a complete block in the buffer.

Figure 17-17 provides a summary:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 17-17. DMA Receive Mode



17.3.5.1.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal SDMAWREQN is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the SD_BLK[10:0] BLEN field.

The SDMAWREQN signal is deasserted to its inactive level when the sDMA has written one single word to the buffer.

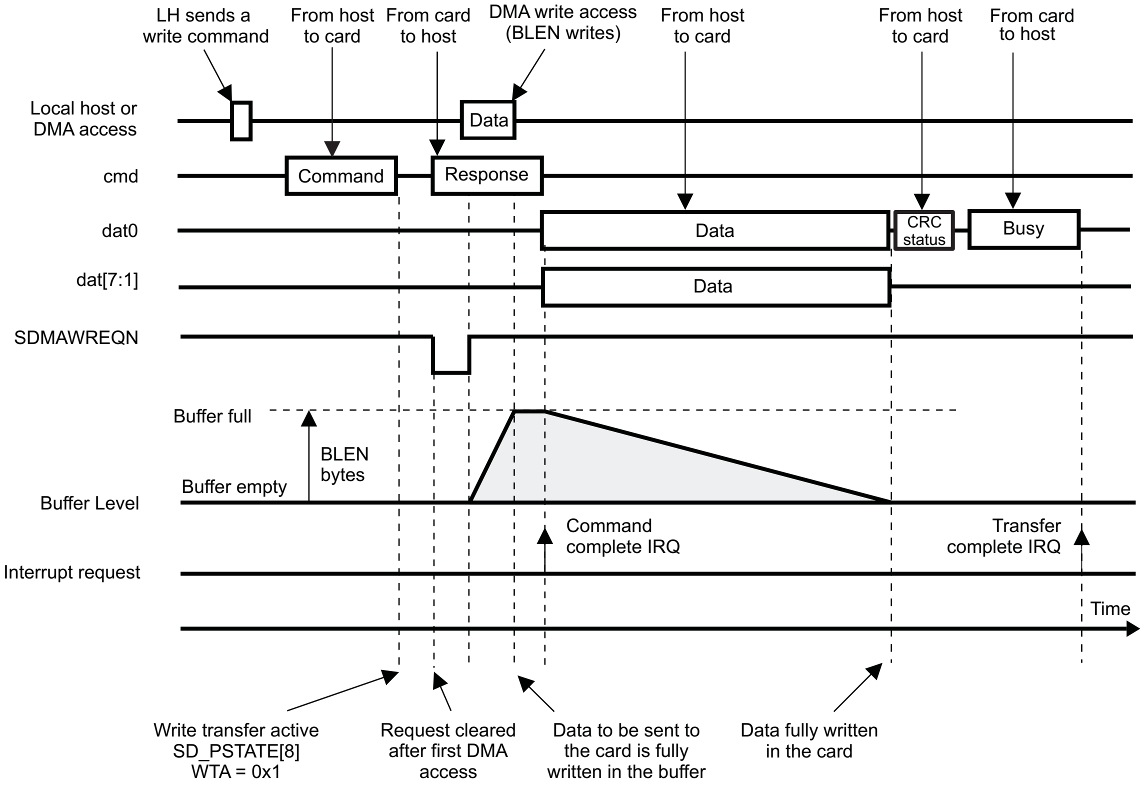
Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

New DMA requests are internally masked if the sDMA has not written exactly BLEN bytes (as DMA accesses are in 32-bit, then the number of sDMA read is Integer(BLEN/4)+1) and if there is not enough memory space to write a complete block in the buffer.

Figure 17-18 provides a summary:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 17-18. DMA Transmit Mode



17.3.6 Mode Selection

The MMC/SD/SDIO host controller can be use in two modes, MMC and SD/SDIO modes. It has been designed to be the most transparent with the type of card. The type of the card connected is differentiated by the software initialization procedure.

Software identifies the type of card connected during software initialization. For each given card type, there are corresponding commands. Some commands are not supported by all cards. See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, and the *SDIO Card Specification, Part E1* for more details.

The purpose of the module is to transfer commands and data, to whatever card is connected, respecting the protocol of the connected card. Writes and reads to the card must respect the appropriate protocol of that card.

17.3.7 Buffer Management

17.3.7.1 Data Buffer

The MMC/SD/SDIO host controller uses a data buffer. This buffer transfers data from one data bus (Interconnect) to another data bus (SD, SDIO, or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (L4 and the card). To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than the one of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the data buffer, the prefetch buffer, and the post-write buffer is the 32-bit register SD_DATA. A write access to the SD_DATA register followed by a read access from the SD_DATA register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the SD_DATA register and the data of the read access to the SD_DATA register are different.

The number of 32-bit accesses to the SD_DATA register that are needed to read (or write) a data block with a size of SD_BLK[10:0] BLEN, and equals the rounded up result of BLEN divided by 4. The maximum block size supported by the host controller is hard-coded in the register SD_CAPA[17:16] MBL field and cannot be changed.

A read access to the SD_DATA register is allowed only when the buffer read enable status is set to 1 (SD_PSTATE[11] BRE); otherwise, a bad access (SD_STAT[29] BADA) is signaled.

A write access to the SD_DATA register is allowed only when the buffer write enable status is set to 1 (SD_PSTATE[10] BWE); otherwise, a bad access (SD_STAT[29] BADA) is signaled and the data is not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to MEM_SIZE/2 (in double buffering), two data transfers can occur from one data bus to the other data bus and vice versa at the same time. The MMC/SD/SDIO controller uses the two portions of the data buffer in a ping-pong manner so that storing and reading of the first and second portions of the data buffer are automatically interchanged from time to time so that data may be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) is being stored into the other portion and vice versa. When BLEN is less than or equal to 200h (that is, less or equal to 512Bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32-bits x BLEN div by 4). Not more than this total size of 2 times 32-bits × BLEN div by 4 can be used.
- When the size of the data block to transfer is larger than MEM_SIZE/2, only one data transfer can occur from one data bus to the other data bus at a time. The MMC/SD/SDIO host controller uses the entire data buffer as a single portion. In this mode, a bad access (SD_STAT[29] BADA) is signaled when two data transfers occur from one data bus to the other data bus and vice versa at the same time.

CAUTION

The SD_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

Figure 17-19 shows the buffer management for writing and Figure 17-20 shows the buffer management for reading.

Figure 17-19. Buffer Management for a Write

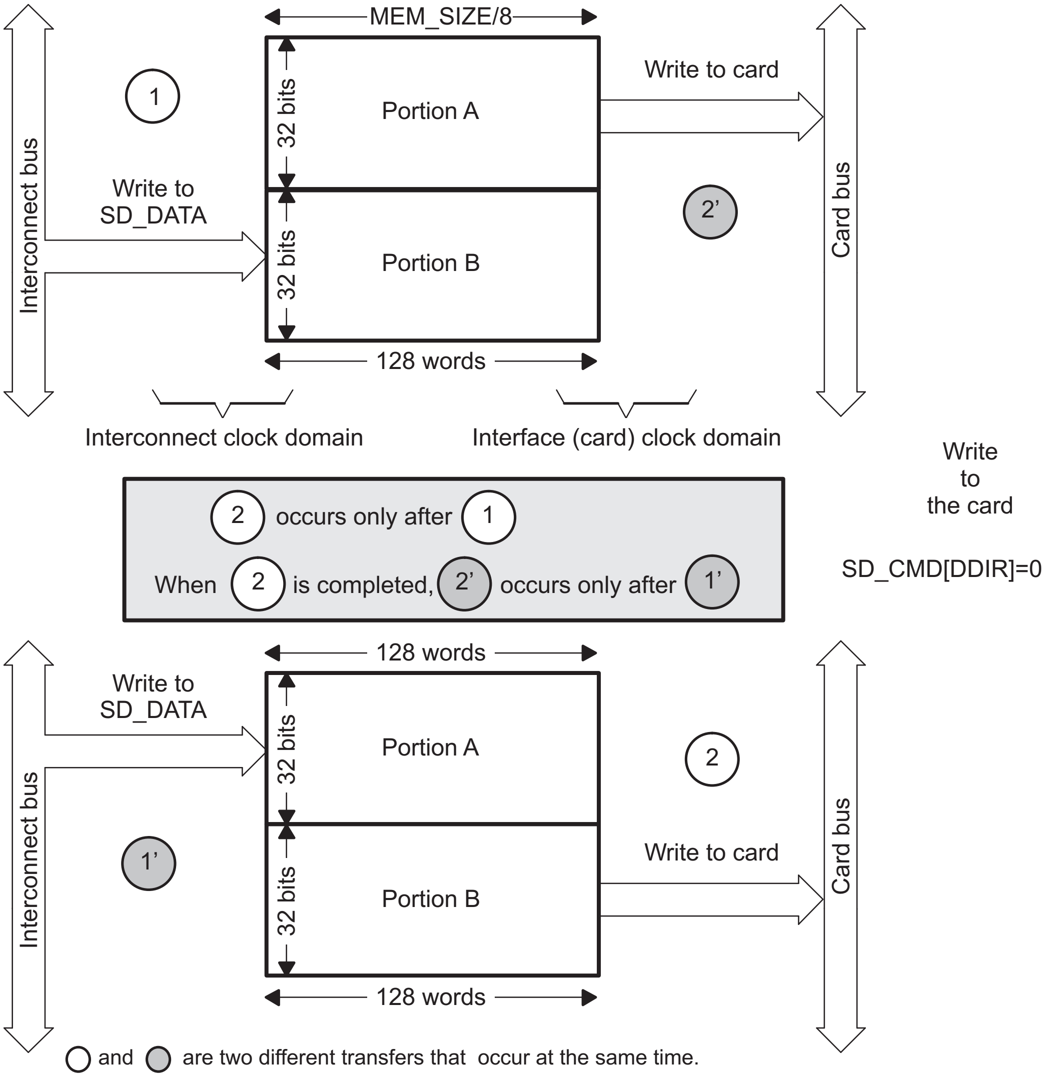


Figure 17-20. Buffer Management for a Read

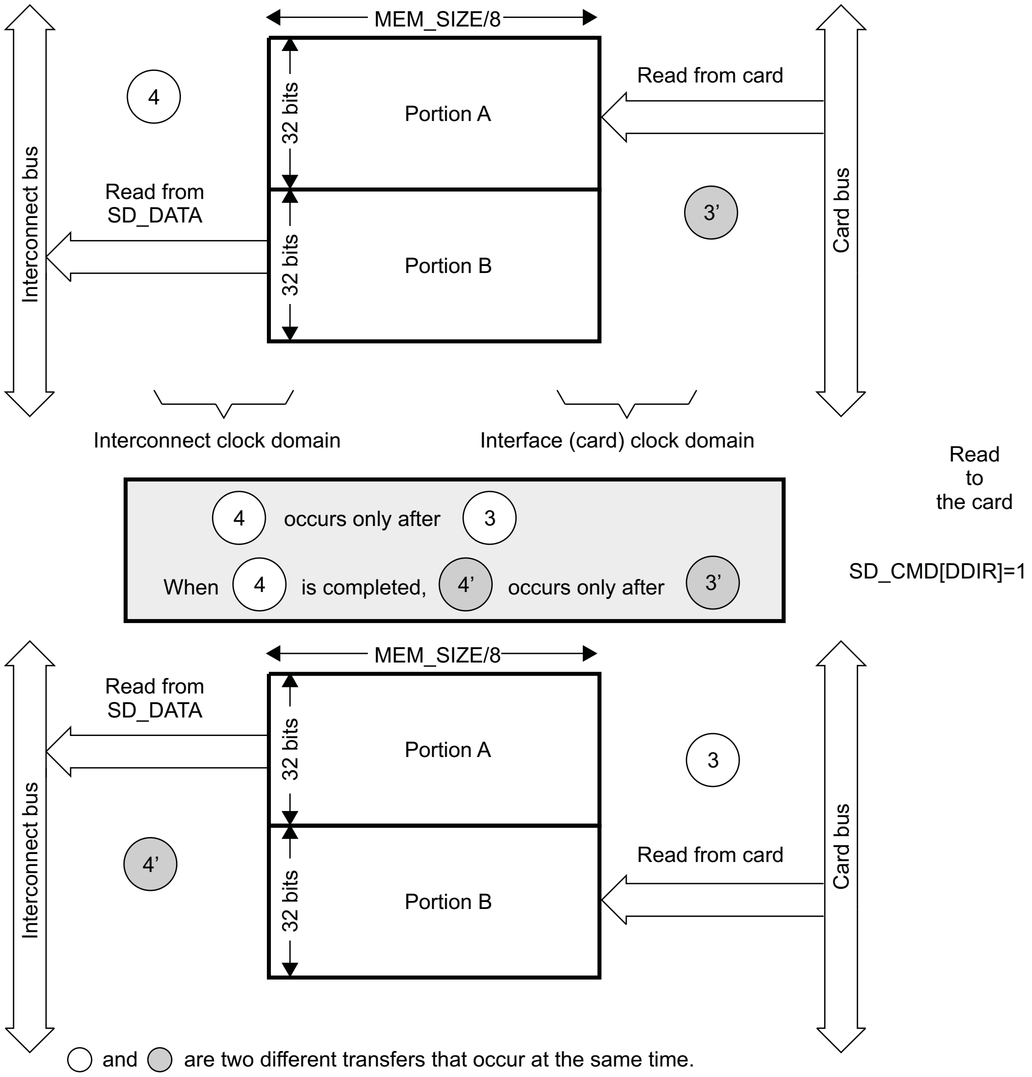


17.3.7.1.1 Memory Size, Block Length, and Buffer Management Relationship

The maximum block length and buffer management that can be targeted by system depend on memory depth setting.

Table 17-12. Memory Size, BLEN, and Buffer Relationship

Memory Size([5:2] MEMSIZE in bytes)	512	1024	2048	4096
Maximum block length supported	512	1024	2048	2048
Double-buffering for maximum block length	N/A	BLEN <= 512	BLEN <= 1024	BLEN <= 2048
Single-buffering for block length	BLEN<=512	512 < BLEN <= 1024	1024 < BLEN <= 2048	N/A

17.3.7.1.2 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers (see):
  - SD_STAT[29] BADA Bad access to data space
  - SD_STAT[5] BRR Buffer read ready
  - SD_STAT[4] BWR Buffer write ready
- Status registers (see):
  - SD_PSTATE[11] BRE Buffer read enable
  - SD_PSTATE[10] BWE Buffer write enable

17.3.8 Transfer Process

The process of a transfer is dependent on the type of command. It can be with or without a response, with or without data.

17.3.8.1 Different Types of Commands

Different types of commands are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, the *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification* for more details.

17.3.8.2 Different Types of Responses

Different types of responses are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, the *SD Memory Card Specifications*, the *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification* for more details.

Table 17-13 shows how the MMC, SD, and SDIO responses are stored in the SD_RSPxx registers.

Table 17-13. MMC, SD, SDIO Responses in the SD_RSPxx Registers

Kind of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6, R7	RESP[39:8][1]	SD_RSP10[31:0]
R1b (Auto CMD12 response)	RESP[39:8][1]	SD_RSP76[31:0]
R2	RESP[127:0][1]	SD_RSP76[31:0] SD_RSP54[31:0] SD_RSP32[31:0] SD_RSP10[31:0]

[1] RESP refers to the command response format described in the specifications mentioned above.

When the host controller modifies part of the SD_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the SD_RSP76[31:0] register because the Host Controller may have a multiple block data DAT line transfer executing concurrently with a command. This allows the host controller to avoid overwriting the Auto CMD12 response with the command response stored in SD_RSP10 register and vice versa.

17.3.9 Transfer or Command Status and Error Reporting

Flags in the MMC/SD/SDIO host controller show status of communication with the card:

- A timeout (of a command, a data, or a response)
- A CRC

Error conditions generate interrupts. See Table 17-14 and register description for more details.

Table 17-14. CC and TC Values Upon Error Detected

Error hold in the SD_STAT Register		CC	TC	Comments
29	BADA			No dependency with CC or TC. BADA is related to the register accesses. Its assertion is not dependent of the ongoing transfer.
28	CERR	1		CC is set upon CERR.
22	DEB		1	TC is set upon DEB.
21	DCRC		1	TC is set upon DCRC.
20	DTO			DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO.
19	CIE	1		CC is set upon CIE.
18	CEB	1		CC is set upon CEB.
17	CCRC	1		CC can be set upon CCRC - See CTO comment
16	CTO			CTO and CC are mutually exclusive. CIE, CEB and CERR cannot occur with CTO. CTO can occur at the same time as CCRC it indicates a command abort due to a contention on CMD line. In this case no CC appears.

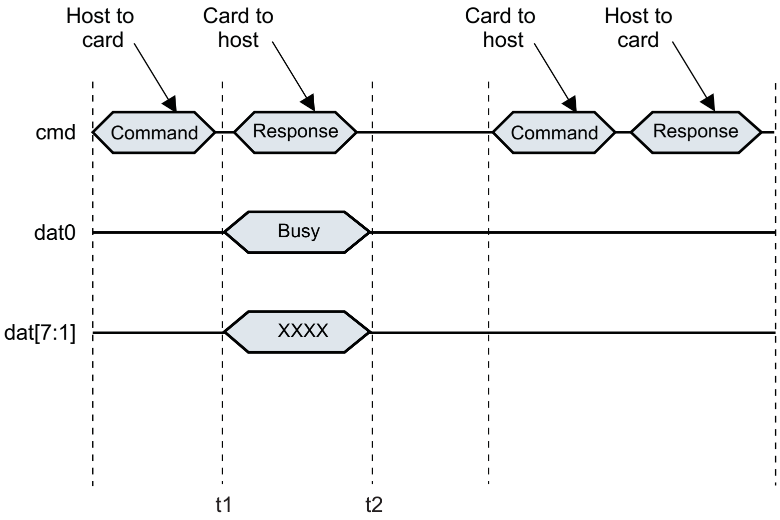
SD_STAT[21] DCRC event can be asserted in the following conditions:

- Busy timeout for R1b, R5b response type
- Busy timeout after write CRC status
- Write CRC status timeout
- Read data timeout
- Boot acknowledge timeout

17.3.9.1 Busy Timeout for R1b, R5b Response Type

Figure 17-21 shows DCRD event condition asserted when there is a busy timeout for R1b or R5b responses.

Figure 17-21. Busy Timeout for R1b, R5b Responses



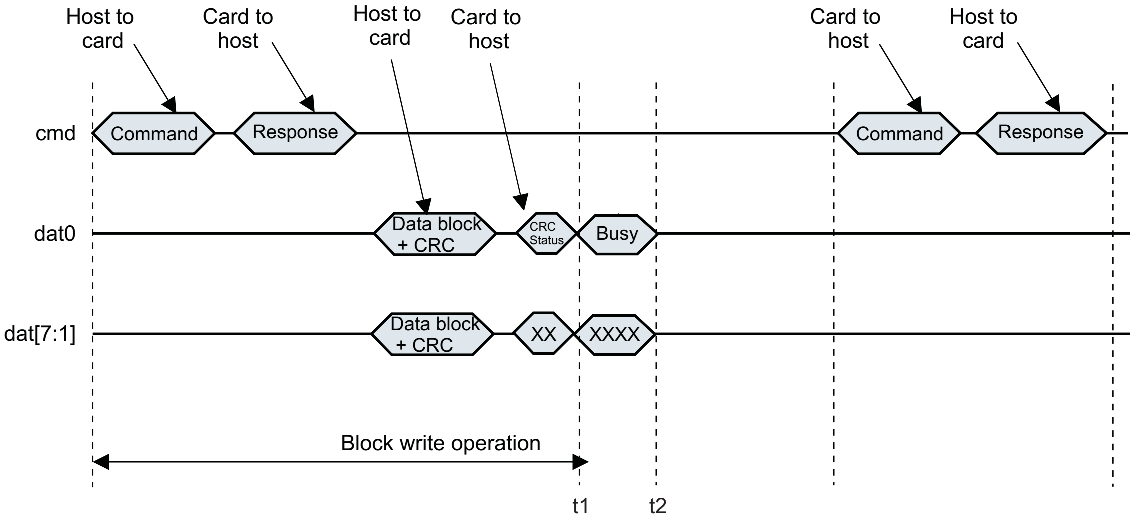
t1 - Data timeout counter is loaded and starts after R1b, R5b response type.

t2 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

17.3.9.2 Busy Timeout After Write CRC Status

Figure 17-22 shows DCRC event condition asserted when there is busy timeout after write CRC status.

Figure 17-22. Busy Timeout After Write CRC Status



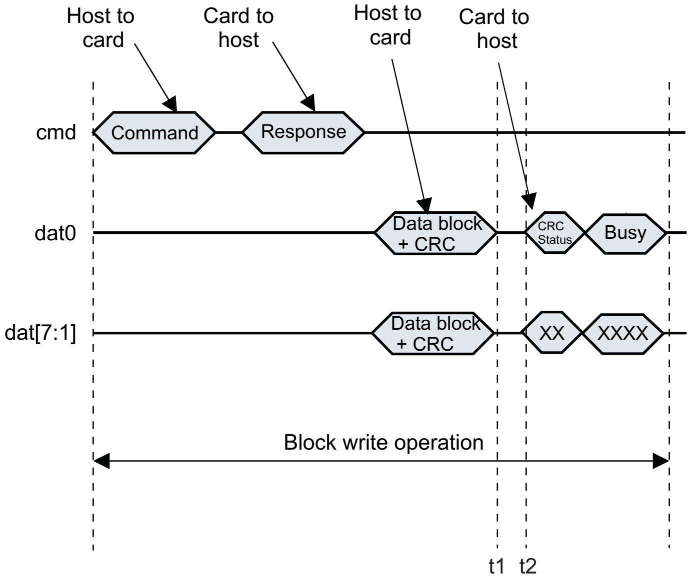
t1 - Data timeout counter is loaded and starts after CRC status.

t2 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

17.3.9.3 Write CRC Status Timeout

Figure 17-23 shows DCRC event condition asserted when there is write CRC status timeout.

Figure 17-23. Write CRC Status Timeout



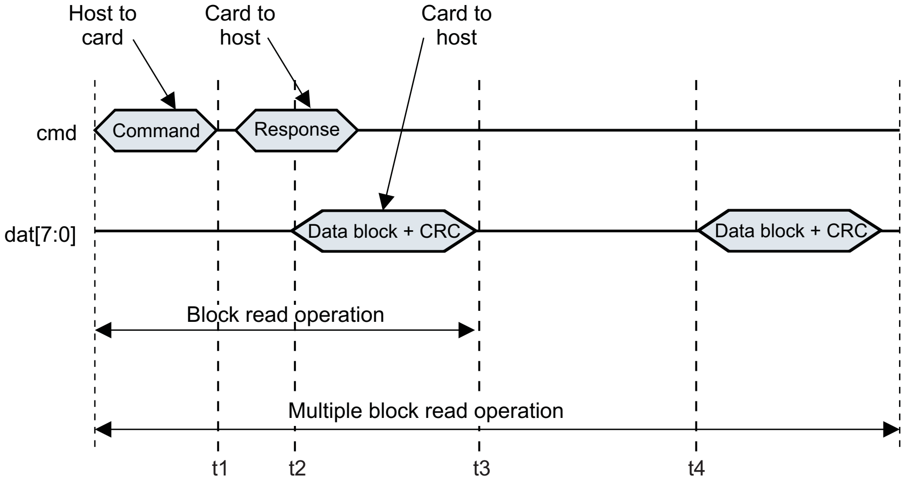
t1 - Data timeout counter is loaded and starts after Data block + CRC.

t2 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

17.3.9.4 Read Data Timeout

Figure 17-24 shows DCRC event condition asserted when there is read data timeout.

Figure 17-24. Read Data Timeout



t1 - Data timeout counter is loaded and starts after Command transmission.

t2 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

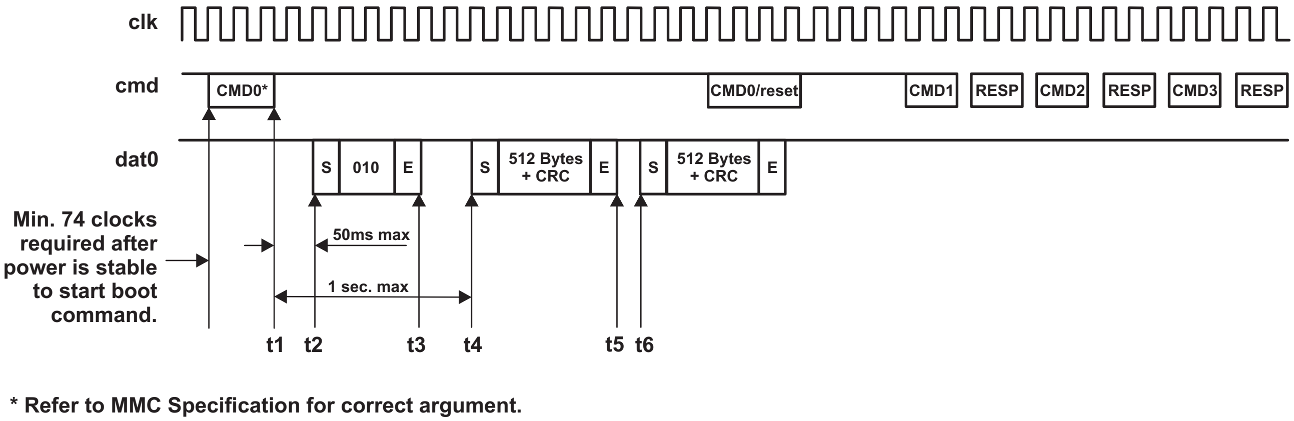
t3 - Data timeout counter is loaded and starts after Data block + CRC transmission.

t4 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

17.3.9.5 Boot Acknowledge Timeout

Figure 17-25 shows DCRC event condition asserted when there is boot acknowledge timeout and CMD0 is used.

Figure 17-25. Boot Acknowledge Timeout When Using CMD0



t1 - Data timeout counter is loaded and starts after CMD0.

t2 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

t3 - Data timeout counter is loaded and starts.

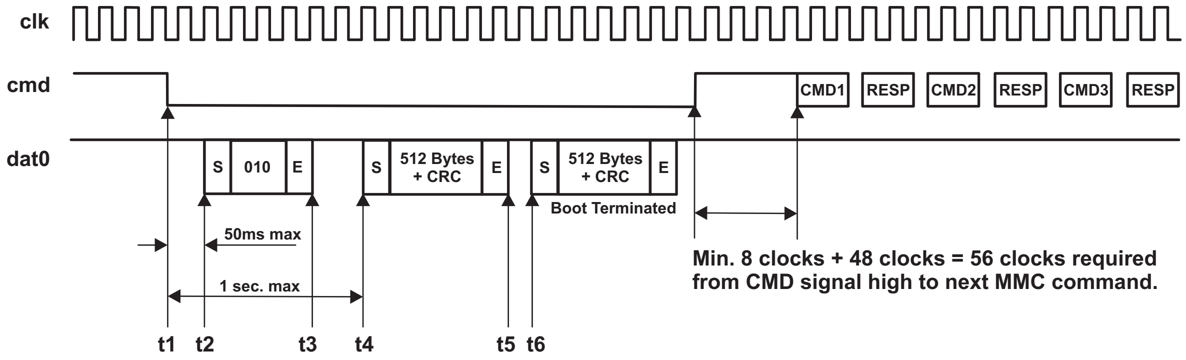
t4 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

t5 - Data timeout counter is loaded and starts after Data + CRC transmission.

t6 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

Figure 17-26 shows DCRC event condition asserted when there is boot acknowledge timeout and CMD line is held low.

Figure 17-26. Boot Acknowledge Timeout When CMD Held Low



t1 - Data timeout counter is loaded and starts after cmd line is tied to 0.

t2 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

t3 - Data timeout counter is loaded and starts.

t4 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

t5 - Data timeout counter is loaded and starts after Data + CRC transmission.

t6 - Data timeout counter stops and if it is 0, SD_STAT[21] DCRC is generated.

17.3.10 Auto Command 12 Timings

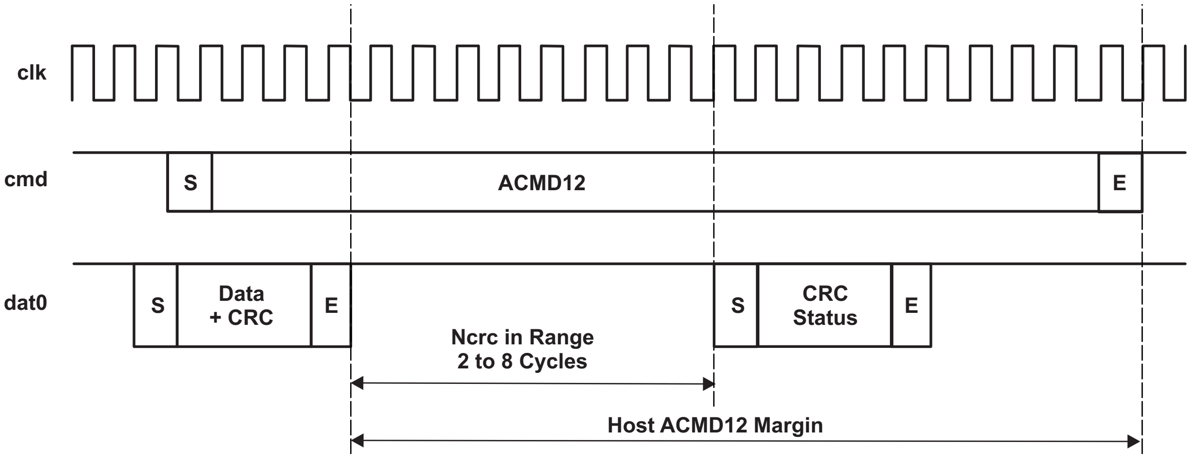
With the UHS definition of SD cards with higher frequency for MMC clocks up to 208, SD standard imposes a specific timing for Auto CMD12 "end bit" arrival.

17.3.10.1 Auto Command 12 Timings During Write Transfer

A margin named Ncrc in range of 2 to 8 cycles has been defined for SDR50 and SDR104 card components for write data transfers, as auto command 12 'end bit' shall arrive after the CRC status "end bit".

Figure 17-27 shows auto CMD12 timings during write transfer.

Figure 17-27. Auto CMD12 Timing During Write Transfer



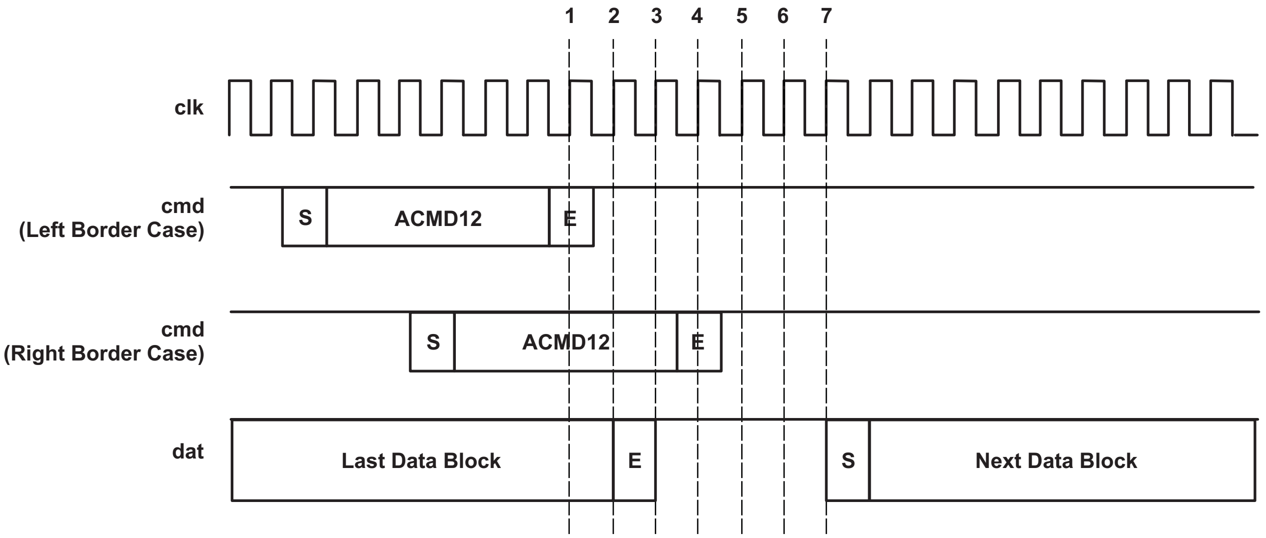
The Host controller has a margin of 18 clock cycles to make sure that auto CMD12 'end bit' arrives after the CRC status. This margin does not depend on MMC bus configuration, DDR or standard transfer, 1,4 or 8 bus width.

17.3.10.2 Auto Command 12 Timings During Read Transfer

With UHS very high speed cards gap timing between 2 successive cards has been extended to 4 cycles instead of 2. By the way it gives more flexibility for Host Auto CMD12 arrival in order to receive the last complete and reliable block. SD controller only follows the 'Left Border Case' defined by SD UHS specification.

Figure 17-28 shows ACMD12 timings during read transfer.

Figure 17-28. Auto Command 12 Timings During Read Transfer



The Auto CMD12 arrival sent by the Host controller is not sensitive to the MMC bus configuration whether it is DDR or standard transfer and whether it is a 1,4 or 8 bit bus width transfer.

17.3.11 Transfer Stop

Whenever a transfer is initiated, the transmission may be willed to stop whereas it is still not finished. Several cases can be faced depending on the transfer type:

- Multiple blocks oriented transfers (for which transfer length is known)
- Continuous stream transfers (which have an infinite length)

NOTE: Since the MMC/SD/SDIO controller manages transfers based on a block granularity, the buffer will accept a block only if there is enough space to completely store it. Consequently, if a block is pending in the buffer, no command will be sent to the card because the card clock will be shut off by the controller.

The MMC/SD/SDIO controller includes two features which make a transfer stop more convenient and easier to manage:

- Auto CMD12 (for MMC and SD only).

  This feature is enabled by setting the SD_CMD[2] ACEN bit to 1 (this setting is relevant for a MMC/SD transfer with a known number of blocks to transfer). When the Auto CMD12 feature is enabled, the MMC/SD/SDIO controller will automatically issue a CMD12 command when the expected number of blocks has been exchanged.
- Stop at block gap

  This feature is enabled by setting the SD_HCTL[16] SBGR bit to 1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.

Table 17-15 shows the common ways to stop a transfer, indicating command to send and features to enable.

Table 17-15. MMC/SD/SDIO Controller Transfer Stop Command Summary

		WRITE Transfer		**READ Transfer**	
		MMC/SD	SDIO	MMC/SD	SDIO
Single block		Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC
Multi blocks (finite or infinite)	Before the programmed block boundary	Send CMD12 Wait TC	Send CMD52 Wait TC	Send CMD12 Wait TC	Send CMD52 Wait TC
	Stop at the end of the transfer (finite transfer only)	Auto CMD12 active Transfer ends automatically Wait TC	Set SD_HCTL[16] SBGR bit to 1. Send CMD52 Wait TC	Auto CMD12 active Transfer ends automatically Wait TC	**If READ_WAIT supported** Stop at block gap Wait TC
					If READ_WAIT not supported Send CMD52 Wait TC

NOTE: The MMC/SD/SDIO controller will send the stop command to the card on a block boundary, regardless the moment the command was written to the controller registers.

17.3.12 Output Signals Generation

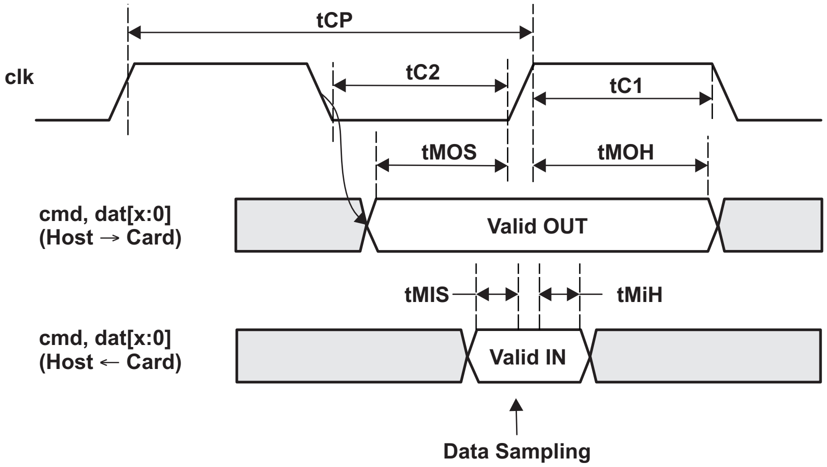
The MMC/SD/SDIO output signals can be driven on either falling edge or rising edge depending on the SD_HCTL[2] HSPE bit. This feature allows to reach better timing performance, and thus to increase data transfer frequency.

17.3.12.1 Generation on Falling Edge of MMC Clock

The controller is by default in this mode to maximize hold timings. In this case, SD_HCTL[2] HSPE bit is cleared to 0.

Figure 17-29 shows the output signals of the module when generating from the falling edge of the MMC clock.

Figure 17-29. Output Driven on Falling Edge



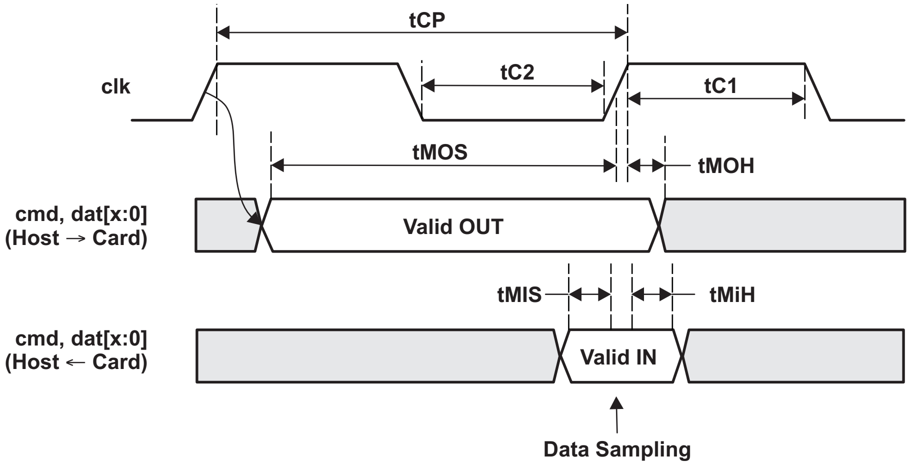
17.3.12.2 Generation on Rising Edge of MMC Clock

This mode increases setup timings and allows reaching higher bus frequency. This feature is activated by setting SD_HCTL[2] HSPE bit to 1. The controller shall be set in this mode to support SDR transfers.

NOTE: Do not use this feature in Dual Data Rate mode (when SD_CON[19] DDR is set to 1).

Figure 17-30 shows the output signals of the module when generating from the rising edge of the MMC clock.

Figure 17-30. Output Driven on Rising Edge



17.3.13 Card Boot Mode Management

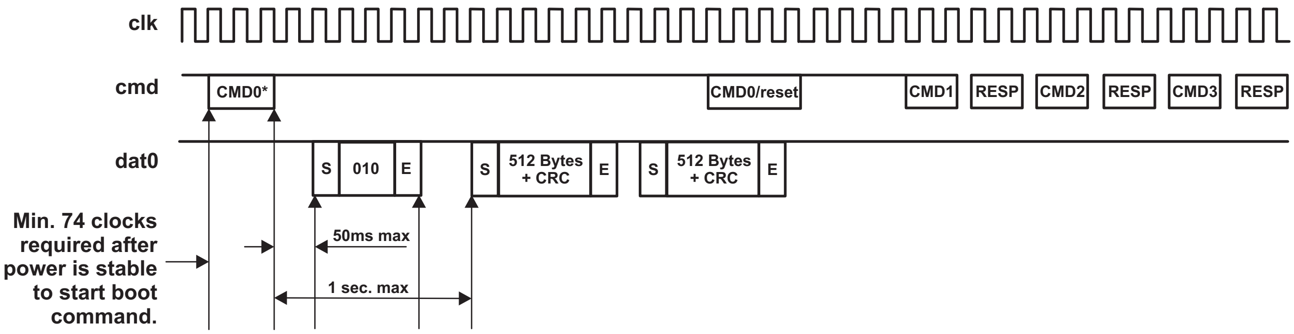
Boot Operation Mode allows the MMC/SD/SDIO host controller to read boot data from the connected slave (MMC device) by keeping CMD line low after power-on (or sending CMD0 with specific argument) before issuing CMD1. The data can be read from either boot area or user area, depending on register setting. Power-on boot defines a way for the boot-code to be accessed by the MMC/SD/SDIO host controller without an upper-level software driver, speeding the time it takes for a controller to access the boot code.

The two possible ways to issue a boot command (either issuing a CMD0 or driving the CMD line to 0 during the whole boot phase) are described in the following sections.

17.3.13.1 Boot Mode Using CMD0

Figure 17-31 shows the timing diagram of a boot sequence using CMD0.

Figure 17-31. Boot Mode With CMD0



*** Refer to MMC Specification for correct argument.**

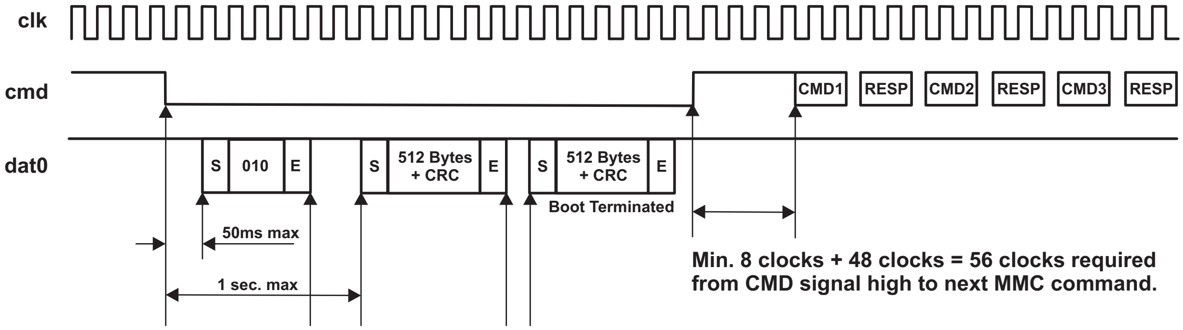
- Configure:
  - SD_CON[BOOT_CF0] to 0
  - SD_CON[BOOT_ACK] (if an acknowledge will be received) to 0x1
  - SD_BLK with the correct block length and number of block
  - SD_SYSCTL[DTO] for timeout

    If transfer is done in DDR mode also set SD_CON[DDR] to 1.
- Write register SD_ARG with correct argument (see MMC Specification).
- Write in SD_CMD register to start CMD0 transfer with these bit fields set:
  - INDX set to 0x00
  - DP set to ‘1’
  - DDIR set to ‘1’
  - MSBS set to ‘1’
  - BCE set to ‘1’
- If boot status is not received within the timing defined, the SD_STAT[DTO] will be generated. Otherwise the SD_STAT[BSR] is arisen.
- After the transfer is complete, the controller will generate the SD_STAT[TC], and then the system can emit another CMD0 (SD_CON[BOOT_ACK] previously cleared to 0x0) to exit the card from boot state.
- If the system wants to abort the boot sequence it must issue a CMD0 with SD_CMD[CMD_TYPE] set to 0x3 (SD_CON[BOOT_ACK] previously cleared to 0x0) during the transfer to abort transfer and enable card to exit from boot state.

17.3.13.2 Boot Mode With CMD Held Low

Figure 17-32 shows the timing diagram of a boot sequence with CMD line tied to 0.

Figure 17-32. Boot Mode With CMD Line Tied to 0



- Configure:
  - SD_CON[BOOT_CF0] and SD_CON[BOOT_ACK] (if an acknowledge will be received) to 0x1
  - SD_BLK with correct block length and number of block
  - SD_SYSCTL[DTO] for timeout

  If transfer is done in DDR mode also set SD_CON[DDR] to 1.
- Write in SD_CMD register to start boot sequence with:
  - DP set to '1'
  - DDIR set to '1'
  - MSBS set to '1'
  - BCE set to '1'

  This leads the controller to force CMD line to '0'.
- If the boot status is not received within the timing defined, the SD_STAT[DTO] will be generated. Otherwise the SD_STAT[BSR] is arisen.
- After the transfer is complete, the controller will generate the SD_STAT[TC], and then the system must clear SD_CON[BOOT_CF0] to 0x0 to release the CMD line and enable the card to exit from boot state.
- If the system wants to abort the boot sequence it must clear SD_CON[BOOT_CF0] to 0x0 during transfer to enable the card to exit from boot state.

17.3.14 CE-ATA Command Completion Disable Management

The MMC/SD/SDIO controller supports CE-ATA features, in particular the detection of command completion token. When a command that requires a command completion signal (SD_CON[12] CEATA and SD_CMD[2] ACEN set to 1) is launched, the host system is no longer allowed to emit a new command in parallel of data transfer unless it is a command completion disable token.

The settings to emit a command completion disable token follow:

- SD_CON[12] CEATA is set to 1.
- SD_CON[2] HR set to 1.
- Clear the SD_ARG register.
- Write into SD_CMD register with value 0000 0000h.

When a command completion disable token was emitted (that is, SD_STAT[0] CC received), the host system is again allowed to emit another type of command (for example a transfer abort command CMD12 to abort transfer).

A critical case can be met when command completion signal disable (CCSD) is emitted during the last data block transfer, the sequence on command line could be sent very close to command completion signal (CCS) token sent by the card.

Three cases can be met:

- CCS is receive just before CCSD is emitted:

  An interrupt CIRQ is generated with CCS detection, CCSD is transmitted to card then an interrupt CC is generated when CCSD ends. In this case, card consider the CCSD sequence.
- CCS is not generated or generated during the CCSD transfer:

  The CCS bit cannot be detected (conflict is not possible as they drive the same level on command line, then no CIRQ interrupt is generated; besides CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:

  Only the interrupt CIRQ is generated when CCS is detected.

17.3.15 Test Registers

Test registers are available to be compliant with SD Host controller specification. This feature is useful to generate interrupts manually for driver debugging. The Force Event register (SD_FE) is used to control the Error Interrupt Status and Auto CMD12 Error Status. The System Test register (SD_SYSTEST) is used to control the signals that connect to I/O pins when the module is configured in system test (SD_CON[4] MODE = 1) mode for boundary connectivity verification.

17.3.16 MMC/SD/SDIO Hardware Status Features

Table 17-16 summarizes the MMC/SD/SDIO hardware status features.

Table 17-16. MMC/SD/SDIO Hardware Status Features

Feature	Type	Register/Bit Field/Observability Control	Description
Interrupt flags		See Section 17.3.4.	
CMD line signal level	Status	[24] CLEV	Indicates the level of the cmd line
DAT lines signal level	Status	[23:20] DLEV	Indicates the level of the data lines
Buffer read enable	Status	[11] BRE	Readable data exists in the buffer.
Buffer write enable	Status	[10] BWE	Indicates whether there is enough space in the buffer to write BLEN bytes of data
Read transfer active	Status	[9] RTA	This status is used for detecting completion of a read transfer.
Write transfer active	Status	[8] WTA	This status indicates a write transfer active.
Data line active	Status	[2] DLA	Indicates whether the data lines are active
Command Inhibit (data lines)	Status	[1] DATI	Indicates whether issuing of command using data lines is allowed
Command inhibit (CMD line)	Status	[0] CMDI	Indicates whether issuing of command using CMD line is allowed

17.4 Low-Level Programming Models

17.4.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the module has to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMC/SD/SDIO modules.

Table 17-17. Global Init for Surrounding Modules

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information, see Chapter 6, *Power, Reset, and Clock Management*.
Control module	Module-specific pad muxing and configuration must be set in the control module. See Chapter 7, *Control Module*.
(optional) MPU INTC	MPU INTC configuration must be done to enable the interrupts from the SD module. See Chapter 8, *Interrupts*.
(optional) EDMA	DMA configuration must be done to enable the module DMA channel requests. See Chapter 10, *EDMA*.
(optional) Interconnect	For more information about the interconnect configuration, see Chapter 4, *Interconnects*.

NOTE: The MPU interrupt controller and the EDMA configurations are necessary, if the interrupt and DMA based communication modes are used.

17.4.2 MMC/SD/SDIO Controller Initialization Flow

The next sections outline the four steps to initialize the MMC/SD/SDIO controller:

- Initialize Clocks
- Software reset of the controller
- Set module's hardware capabilities
- Set module's Idle and Wake-Up modes

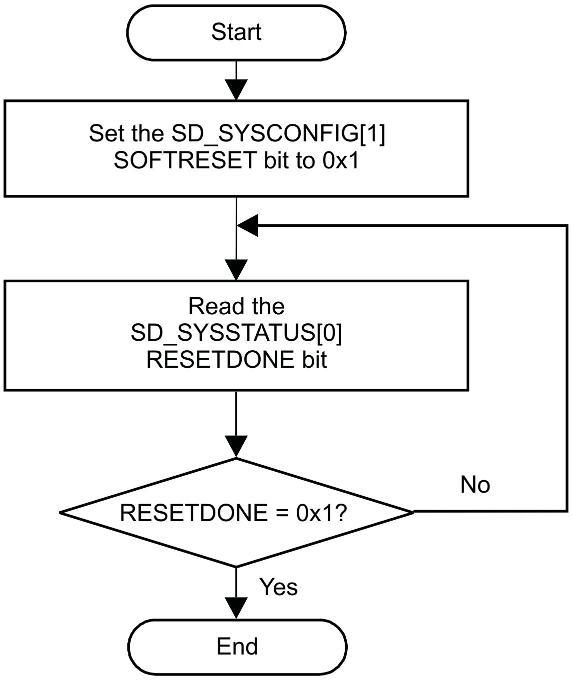
17.4.2.1 Enable OCP and CLKADPI Clocks

Prior to any SD register access one must enable the SD OCP clock and CLKADPI clock in PRCM module registers. For more information, see Chapter 6, *Power, Reset, and Clock Management*.

17.4.2.2 SD Soft Reset Flow

Figure 17-33 shows the soft reset process of MMC/SD/SDIO controller.

Figure 17-33. MMC/SD/SDIO Controller Software Reset Flow



17.4.2.3 Set SD Default Capabilities

Software must read capabilities (in boot ROM for instance) and is allowed to set (write) SD_CAPA[26:24] and SD_CUR_CAPA[23:0] registers before the MMC/SD/SDIO host driver is started.

17.4.2.4 Wake-Up Configuration

Table 17-18 details SD controller wake-up configuration.

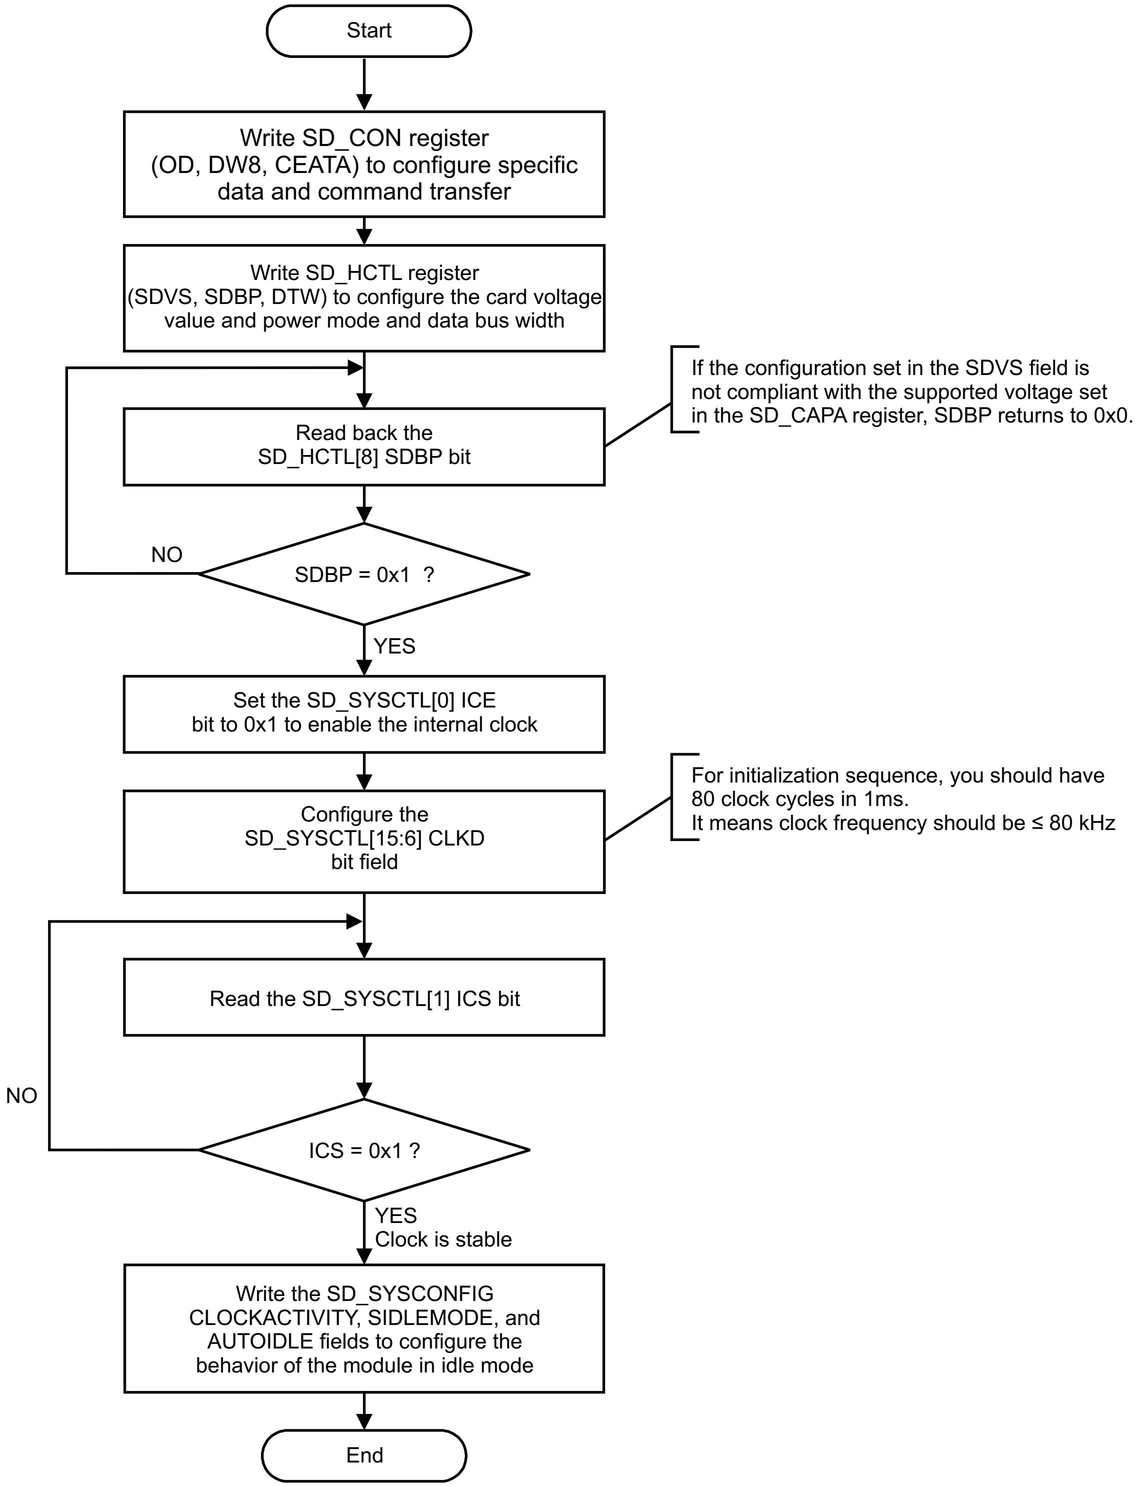
Table 17-18. MMC/SD/SDIO Controller Wake-Up Configuration

Step	Access Type	Register/Bit Field/Programming Model
Configure wake-up bit (if necessary).	W	SD_SYSCONFIG[2] ENAWAKEUP
Enable wake-up events on SD card interrupt (if necessary).	W	SD_HCTL[24] IWE
SDIO Card onlyEnable card interrupt (if necessary).	W	SD_IE[8] CIRQENABLE

17.4.2.5 MMC Host and Bus Configuration

Figure 17-34 details the MMC bus configuration process.

Figure 17-34. MMC/SD/SDIO Controller Bus Configuration Flow



17.4.3 Operational Modes Configuration

17.4.3.1 Basic Operations for MMC/SD/SDIO Host Controller

The MMC/SD/SDIO controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis, rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

17.4.3.2 Card Detection, Identification, and Selection

Figure 17-35 and Figure 17-36 show the card identification and selection process.

Figure 17-35. MMC/SD/SDIO Controller Card Identification and Selection - Part 1

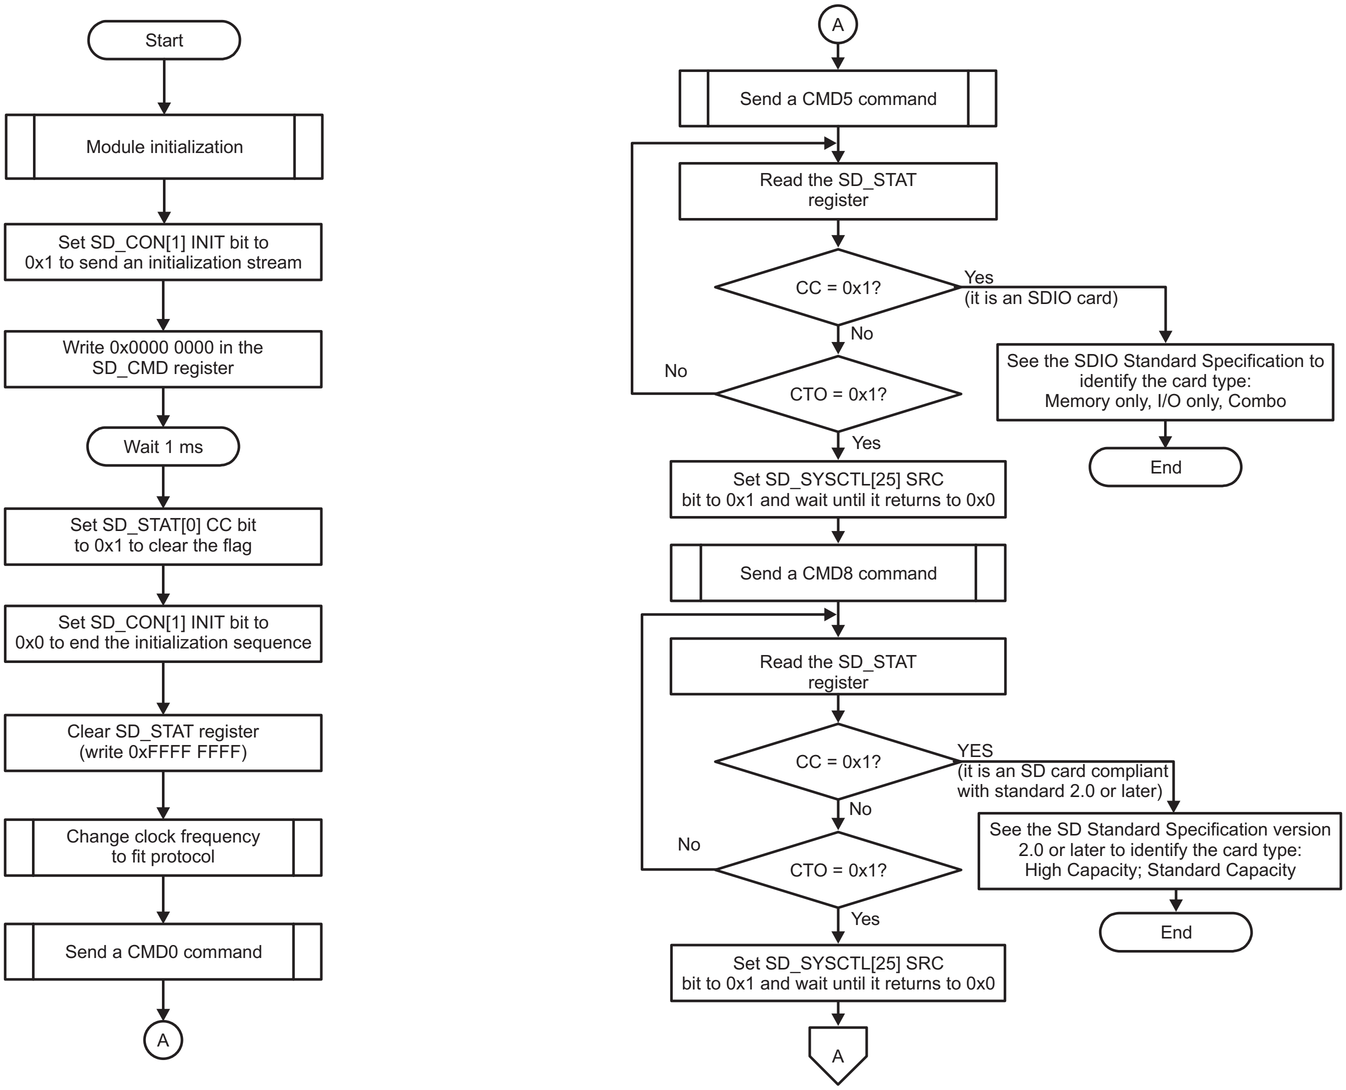


Figure 17-36. MMC/SD/SDIO Controller Card Identification and Selection - Part 2

Bit	Field	Type	Reset	Description
31-14	RESERVED	R	0h	
13-12	STANDBYMODE	R/W	0h	Master interface power Management, standby/wait control. The bit field is only useful when generic parameter MADMA_EN (Master ADMA enable) is set as active, otherwise it is a read only register read a 0. 0h (R/W) = Force-standby. Mstandby is forced unconditionally. 1h (R/W) = No-standby. Mstandby is never asserted. 2h (R/W) = Smart-standby modelocal initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator. IP module shall not generate (initiator-related) wake-up events. 3h (R/W) = Smart-Standby wake-up-capable modelocal initiator standby status depends on local conditions, i.e. the module's functional requirement from the initiator. IP module can generate (master-related) wake-up events when in standby state. Mode is only relevant if the appropriate IP module "mwake-up" output is implemented. Functional clock is maintained. Interface clock may be switched off.
11-10	RESERVED	R	0h	
9-8	CLOCKACTIVITY	R/W	0h	Clocks activity during wake up mode period. Bit 8 is the Interface clock. Bit 9 is the Functional clock. 0h (R/W) = Interface and Functional clock may be switched off. 1h (R/W) = Interface clock is maintained. Functional clock may be switched-off. 2h (R/W) = Functional clock is maintained. Interface clock may be switched-off. 3h (R/W) = Interface and Functional clocks are maintained.
7-5	RESERVED	R	0h	

Table 17-20. SD_SYSCONFIG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4-3	SIDLEMODE	R/W	0h	Power management 0h (R/W) = If an idle request is detected, the MMC/SD/SDIO host controller acknowledges it unconditionally and goes in Inactive mode. Interrupt and DMA requests are unconditionally deasserted. 1h (R/W) = If an idle request is detected, the request is ignored and the module keeps on behaving normally. 2h (R/W) = If an idle request is detected, the module will switch to wake up mode based on its internal activity, and the wake up capability can be used if the wake up capability is enabled (bit SD_SYSCONFIG[2] ENAWAKEUP bit is set to 1). 3h (R/W) = Reserved.
2	ENAWAKEUP	R/W	0h	Wake-up feature control 0h (R/W) = Wake-up capability is disabled. 1h (R/W) = Wake-up capability is enabled.
1	SOFTRESET	R/W	0h	Software reset. The bit is automatically reset by the hardware. During reset, it always returns 0. 0h (W) = No effect 0h (R) = Normal mode 1h (W) = Trigger a module reset. 1h (R) = The module is reset.
0	AUTOIDLE	R/W	0h	Internal Clock gating strategy 0h (R/W) = Clocks are free-running. 1h (R/W) = Automatic clock gating strategy is applied, based on the interconnect and MMC interface activity.

17.5.1.2 SD_SYSSTATUS Register (Offset = 114h) [reset = 0h]

SD_SYSSTATUS is shown in Figure 17-38 and described in Table 17-21.

Return to Summary Table.

This register provides status information about the module excluding the interrupt status information.

17.5.1.3 SD_CSRE Register (Offset = 124h) [reset = 0h]

SD_CSRE is shown in Figure 17-39 and described in Table 17-22.

Return to Summary Table.

This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit SD_CSRE[i] is set to 1, if the corresponding bit at the same position in the response SD_RSP10[I] is set to 1, the host controller indicates a card error (SD_STAT[28] CERR bit) interrupt status to avoid the host driver reading the response register (SD_RSP10). No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register (SD_RSP76) for possible card errors.

17.5.1.4 SD_SYSTEST Register (Offset = 128h) [reset = 0h]

SD_SYSTEST is shown in Figure 17-40 and described in Table 17-23.

Return to Summary Table.

This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification. In SYSTEST mode, a write into SD_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (SD_BLK[10:0] BLEN bits) and the Blocks count for current transfer (SD_BLK[31:16] NBLK bits) are needed to generate a Buffer write ready interrupt (SD_STAT[4] BWR bit) or a Buffer read ready interrupt (SD_STAT[5] BRR bit) and DMA requests if enabled.

5	D1D	R/W	0h	DAT1 input/output signal data value. 0h (W) = If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT1 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect. 0h (R) = If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT1 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0. 1h (R) = If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT1 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1. 1h (W) = If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT1 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect.
4	D0D	R/W	0h	DAT0 input/output signal data value. 0h (W) = If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT0 line is driven low. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect. 0h (R) = If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT0 line (low). If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0. 1h (W) = If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT0 line is driven high. If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect. 1h (R) = If SD_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT0 line (high) If SD_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1.
3	DDIR	R/W	0h	Control of the DAT [7:0] pins direction. 0h (W) = The DAT lines are outputs (host to card). 0h (R) = No action. Returns 0. 1h (W) = The DAT lines are inputs (card to host). 1h (R) = No action. Returns 1.

Table 17-23. SD_SYSTEST Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	CDAT	R/W	0h	CMD input/output signal data value 0h (W) = If SD_SYSTEST[1] CDIR bit = 0 (output mode direction), the CMD line is driven low. If SD_SYSTEST[1] CDIR bit = 1 (input mode direction), no effect. 0h (R) = If SD_SYSTEST[1] CDIR bit = 1 (input mode direction), returns the value on the CMD line (low). If SD_SYSTEST[1] CDIR bit = 0 (output mode direction), returns 0 . 1h (R) = If SD_SYSTEST[1] CDIR bit = 1 (input mode direction), returns the value on the CMD line (high) If SD_SYSTEST[1] CDIR bit = 0 (output mode direction), returns 1 . 1h (W) = If SD_SYSTEST[1] CDIR bit = 0 (output mode direction), the CMD line is driven high. If SD_SYSTEST[1] CDIR bit = 1 (input mode direction), no effect.
1	CDIR	R/W	0h	Control of the CMD pin direction 0h (W) = The CMD line is an output (host to card). 0h (R) = No action. Returns 0. 1h (W) = The CMD line is an input (card to host) . 1h (R) = No action. Returns 1.
0	MCKD	R/W	0h	MMC clock output signal data value 0h (W) = The output clock is driven low. 0h (R) = No action. Returns 0. 1h (W) = The output clock is driven high. 1h (R) = No action. Returns 1.

17.5.1.5 SD_CON Register (Offset = 12Ch) [reset = 0h]

SD_CON is shown in Figure 17-41 and described in Table 17-24.

Return to Summary Table.

This register is used: To select the functional mode for any card. To send an initialization sequence to any card. To send an initialization sequence to any card. To enable the detection on the mmc_dat[1] signal of a card interrupt for SDIO cards only. It also configures the parameters related to the card detect and write protect input signals

Table 17-24. SD_CON Register Field Descriptions

Bit	Field	Type	Reset	Description
31-22	RESERVED	R	0h	
21	SDMA_LnE	R/W	0h	Slave DMA Level/Edge Request. The waveform of the DMA request can be configured either edge sensitive with early de-assertion on first access to SD_DATA register or late de-assertion, request remains active until last allowed data written into SD_DATA. 0h (R/W) = Slave DMA edge sensitive. 1h (R/W) = Slave DMA level sensitive.
20	DMA_MnS	R/W	0h	DMA Master or Slave selection. When this bit is set and the controller is configured to use the DMA, Ocp master interface is used to get datas from system using ADMA2 procedure (direct access to the memory). This option is only available if generic parameter MADMA_EN is asserted to 1. 0h (R/W) = The controller is slave on data transfers with system. 1h (R/W) = Not available on this device.
19	DDR	R/W	0h	Dual Data Rate mode. When this register is set, the controller uses both clock edge to emit or receive data. Odd bytes are transmitted on falling edges and even bytes are transmitted on rise edges. It only applies on Data bytes and CRC, Start, end bits and CRC status are kept full cycle. This bit field is only meaningful and active for even clock divider ratio of SD_SYSCTL[CLKD], it is insensitive to SD_HCTL[HSPE] setting. Note: DDR mode is not supported on this device. Always set this bit to 0. 0h (R/W) = Standard modeData are transmitted on a single edge. 1h (R/W) = Data Bytes and CRC are transmitted on both edges.

Table 17-24. SD_CON Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18	BOOT_CF0	R/W	0h	Boot Status Supported. This register is set when the CMD line needs to be forced to 0 for a boot sequence. CMD line is driven to 0 after writing in SD_CMD. The line is released when this bit field is de-asserted and aborts data transfer in case of a pending transaction. 0h (W) = CMD line forced to 0 is enabled. 0h (R) = CMD line not forced. 1h (R) = CMD line is released when it was previously forced to 0 by a boot sequence. 1h (W) = CMD line forced to 0 is enabled and will be active after writing into SD_CMD register.
17	BOOT_ACK	R/W	0h	Book acknowledge received. When this bit is set the controller should receive a boot status on DAT0 line after next command issued. If no status is received a data timeout will be generated. 0h (R/W) = No acknowledge to be received. 1h (R/W) = A boot status will be received on DAT0 line after issuing a command.
16	CLKEXTFREE	R/W	0h	External clock free running. This register is used to maintain card clock out of transfer transaction to enable slave module (for example to generate a synchronous interrupt on mmc_dat[1]). The Clock will be maintain only if SD_SYSCTL[2] CEN bit is set. 0h (R/W) = External card clock is cut off outside active transaction period. 1h (R/W) = External card clock is maintain even out of active transaction period only if SD_SYSCTL[2] CEN bit is set.
15	PADEN	R/W	0h	Control power for MMC lines. This register is only useful when MMC PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for mmc_dat[1] , the signal is also combine outside the module with the dedicated power control SD_CON[11] CTPL bit. 0h (R/W) = ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms. 1h (R/W) = ADPIDLE module pin is forced to active state
14-13	RESERVED	R	0h	
12	CEATA	R/W	0h	CE-ATA control mode (MMC cards compliant with CE-ATA). This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is not supported. 0h (R/W) = Standard MMC/SD/SDIO mode. 1h (R/W) = CE-ATA mode. Next commands are considered as CE-ATA commands.
11	CTPL	R/W	0h	Control Power for mmc_dat[1] line (SD cards). By default, this bit is cleared to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current. SDIO cards. When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of mmc_dat[1] outside of a transaction in order to detect asynchronous card interrupt on mmc_dat[1] line and minimize the leakage current of the buffers. 0h (R/W) = Disable all the input buffers outside of a transaction. 1h (R/W) = Disable all the input buffers except the buffer of mmc_dat[1] outside of a transaction.

Table 17-24. SD_CON Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
10-9	DVAL	R/W	0h	Debounce filter value (all cards). This register is used to define a debounce period to filter the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0h (R/W) = 33 us debounce period 1h (R/W) = 231 us debounce period 2h (R/W) = 1 ms debounce period 3h (R/W) = 8.4 ms debounce period
8	WPP	R/W	0h	Write protect polarity (for SD and SDIO cards only). This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0h = Active high level 1h = Active low level
7	CDP	R/W	0h	Card detect polarity (all cards). This bit selects the active level of the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0h = Active high level 1h = Active low level
6	MIT	R/W	0h	MMC interrupt command (MMC cards only). This bit must be set to 1, when the next write access to the command register (SD_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response. 0h (R/W) = Command timeout enabled. 1h (R/W) = Command timeout disabled.
5	DW8	R/W	0h	8-bit mode MMC select (MMC cards only). For SD/SDIO cards, this bit must be cleared to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification. 0h (R/W) = 1-bit or 4-bit data width 1h (R/W) = 8-bit data width
4	MODE	R/W	0h	Mode select (all cards). This bit selects the functional mode. 0h (R/W) = Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. The MMC clock is enabled. MMC/SD transfers are operated under the control of the SD_CMD register. 1h (R/W) = SYSTEST mode. SYSTEST mode. The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.

Table 17-24. SD_CON Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	STR	R/W	0h	Stream command (MMC cards only). This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20WRITE_DAT_UNTIL_STOP). 0h (R/W) = Block oriented data transfer 1h (R/W) = Stream oriented data transfer
2	HR	R/W	0h	Broadcast host response (MMC cards only). This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core. In order to have the host response to be generated in open drain mode, the register SD_CON[OD] must be set to 1. When SD_CON[12] CEATA bit is set to 1 and SD_ARG cleared to 0, when writing 0000 0000h into SD_CMD register, the host controller performs a 'command completion signal disable' token (i.e., mmc_cmd line held to 0 during 47 cycles followed by a 1). 0h (R/W) = The host does not generate a 48-bit response instead of a command. 1h (R/W) = The host generates a 48-bit response instead of a command or a command completion signal disable token.
1	INIT	R/W	0h	Send initialization stream (all cards). When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the mmc_cmd line to 1 during 80 clock cycles. The initialization sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (SD_SYSCTL [15:6] CLKD bits) should be set to ensure that 80 clock periods are greater than 1ms. Note: In this mode, there is no command sent to the card and no response is expected. A command complete interrupt will be generated once the initialization sequence is completed. SD_STAT[0] CC bit can be polled. 0h (R/W) = The host does not send an initialization sequence 1h (R/W) = The host sends an initialization sequence
0	OD	R/W	0h	Card open drain mode (MMC cards only). This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register SD_CON[2] HR bit). 0h (R/W) = No open drain 1h (R/W) = Open drain or broadcast host response

17.5.1.6 SD_PWCNT Register (Offset = 130h) [reset = 0h]

SD_PWCNT is shown in Figure 17-42 and described in Table 17-25.

Return to Summary Table.

This register is used to program a mmc counter to delay command transfers after activating the PAD power, this value depends on PAD characteristics and voltage.

Figure 17-42. SD_PWCNT Register

<table>
<tr><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>

Bit	Field	Type	Reset	Description
31-16	RESERVED	R	0h	
15-0	PWRCNT	R/W	0h	Power counter register. This register is used to introduce a delay between the PAD ACTIVE pin assertion and the command issued. 0h (R/W) = No additional delay added 1h (R/W) = TCF delay (card clock period) 2h (R/W) = TCF x 2 delay (card clock period) FFFEh (R/W) = TCF x 65534 delay (card clock period) FFFFh (R/W) = TCF x 65535 delay (card clock period)

17.5.1.7 SD_SDMASA Register (Offset = 200h) [reset = 0h]

SD_SDMASA is shown in Figure 17-43 and described in Table 17-26.

Return to Summary Table.

This register is used to program a mmc counter to delay command transfers after activating the PAD power. This value depends on PAD characteristics and voltage.

Figure 17-43. SD_SDMASA Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SDMA_SYSADDR																															
R-0h																															

Table 17-26. SD_SDMASA Register Field Descriptions

Bit	Field	Type	Reset	Description
31-0	SDMA_SYSADDR	R	0h	This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value. The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register. The SDMA transfer waits at the every boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the most upper byte of this register (003h) is written, the Host Controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register.

17.5.1.8 SD_BLK Register (Offset = 204h) [reset = 0h]

SD_BLK is shown in Figure 17-44 and described in Table 17-27.

Return to Summary Table.

This register shall be used for any card. SD_BLK[BLEN] is the block size register. SD_BLK[NBLK] is the block count register.

Figure 17-44. SD_BLK Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RESERVED				BLEN											
R-0h				R/W-0h											

Table 17-27. SD_BLK Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	NBLK	R/W	0h	Blocks count for current transfer. This register is enabled when Block count Enable (SD_CMD[1] BCE bit) is set to 1 and is valid only for multiple block transfers. Setting the block count to 0 results no data blocks being transferred. Note: The host controller decrements the block count after each block transfer and stops when the count reaches zero. This register can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value and write operation will be ignored. In suspend context, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, The local host shall restore the previously saved block count. 0h (R/W) = Stop count 1h (R/W) = 1 block 2h (R/W) = 2 blocks FFFFh (R/W) = 65535 blocks
15-12	RESERVED	R	0h	
11-0	BLEN	R/W	0h	Transfer block size. This register specifies the block size for block data transfers. Read operations during transfers may return an invalid value, and write operations are ignored. When a CMD12 command is issued to stop the transfer, a read of the BLEN field after transfer completion (SD_STAT[1] TC bit set to 1) will not return the true byte number of data length while the stop occurs but the value written in this register before transfer is launched. 0h (R/W) = No data transfer 1h (R/W) = 1 byte block length 2h (R/W) = 2 bytes block length 3h (R/W) = 3 bytes block length 1FFh (R/W) = 511 bytes block length 200h (R/W) = 512 bytes block length 7FFh (R/W) = 2047 bytes block length 800h (R/W) = 2048 bytes block length

17.5.1.9 SD_ARG Register (Offset = 208h) [reset = 0h]

SD_ARG is shown in Figure 17-45 and described in Table 17-28.

Return to Summary Table.

This register contains command argument specified as bit 39-8 of Command-Format. These registers must be initialized prior to sending the command itself to the card (write action into the register SD_CMD register). Only exception is for a command index specifying stuff bits in arguments, making a write unnecessary.

Figure 17-45. SD_ARG Register

Table 17-29. SD_CMD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	RESERVED	R	0h	
29-24	INDX	R/W	0h	Command index binary encoded value from 0 to 63 specifying the command number send to card (CMD0 or ACMD0 to CMD63 or ACMD63).
23-22	CMD_TYPE	R/W	0h	Command type. This register specifies three types of special commands: Suspend, Resume and Abort. These bits shall be cleared to 0b00 for all other commands. 0h (R/W) = Others commands 1h (R/W) = Upon CMD52 "Bus Suspend" operation 2h (R/W) = Upon CMD52 "Function Select" operation 3h (R/W) = Upon CMD12 or CMD52 "I/O Abort" command
21	DP	R/W	0h	Data present select. This register indicates that data is present and mmc_dat line shall be used. It must be cleared to 0 in the following conditions: Command using only mmc_cmd line. Command with no data transfer but using busy signal on mmc_dat0. Resume command. 0h (R/W) = Command with no data transfer 1h (R/W) = Command with data transfer
20	CICE	R/W	0h	Command Index check enable. This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (SD_STAT[19] CIE bit set to1) Note: The CICE bit cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. 0h (R/W) = Index check disable 1h (R/W) = Index check enable

Table 17-29. SD_CMD Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	CCCE	R/W	0h	Command CRC check enable. This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (SD_STAT[17] CCRC bit set to 1). Note: The CCCE bit cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued. 0h (R/W) = CRC7 check disable 1h (R/W) = CRC7 check enable
18	RESERVED	R	0h	
17-16	RSP_TYPE	R/W	0h	Response type. This bits defines the response type of the command. 0h (R/W) = No response 1h (R/W) = Response Length 136 bits 2h (R/W) = Response Length 48 bits 3h (R/W) = Response Length 48 bits with busy after response
15-6	RESERVED	R	0h	
5	MSBS	R/W	0h	Multi/Single block select. This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be cleared to 0. 0h (R/W) = Single block. If this bit is 0, it is not necessary to set the register SD_BLK[31:16] NBLK bits. 1h (R/W) = Multi block. When Block Count is disabled (SD_CMD[1] BCE bit is cleared to 0) in Multiple block transfers (SD_CMD[5] MSBS bit is set to 1), the module can perform infinite transfer.
4	DDIR	R/W	0h	Data transfer Direction. Select This bit defines either data transfer will be a read or a write. 0h (R/W) = Data Write (host to card) 1h (R/W) = Data Read (card to host)
3	RESERVED	R	0h	
2	ACEN	R/W	0h	Auto CMD12 Enable (SD cards only). When this bit is set to 1, the host controller issues a CMD12 automatically after the transfer completion of the last block. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop data transfer. In particular, secure commands do not require CMD12. For CE-ATA commands (SD_CON[12] CEATA bit set to 1), auto CMD12 is useless therefore when this bit is set the mechanism to detect command completion signal, named CCS, interrupt is activated. 0h (R/W) = Auto CMD12 disable 1h (R/W) = Auto CMD12 enable or CCS detection enabled.
1	BCE	R/W	0h	Block Count Enable (Multiple block transfers only). This bit is used to enable the block count register (SD_BLK [31:16] NBLK bits). When Block Count is disabled (SD_CMD[1] BCE bit is cleared to 0) in Multiple block transfers (SD_CMD[5] MSBS bits is set to 1), the module can perform infinite transfer. 0h (R/W) = Block count disabled for infinite transfer. 1h (R/W) = Block count enabled for multiple block transfer with known number of blocks
0	DE	R/W	0h	DMA Enable. This bit is used to enable DMA mode for host data access. 0h (R/W) = DMA mode disable 1h (R/W) = DMA mode enable

17.5.1.11 SD_RSP10 Register (Offset = 210h) [reset = 0h]

SD_RSP10 is shown in Figure 17-47 and described in Table 17-30.

Return to Summary Table.

This 32-bit register holds bits positions [31:0] of command response type R1, R1b, R2, R3, R4, R5, R5b, or R6.

17.5.1.15 SD_DATA Register (Offset = 220h) [reset = 0h]

SD_DATA is shown in Figure 17-51 and described in Table 17-34.

Return to Summary Table.

This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bitsx256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput. Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer. Example 1Byte or 16-bit access: Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK. Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK. Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad.

Table 17-35. SD_PSTATE Register Field Descriptions

Bit	Field	Type	Reset	Description
31-25	RESERVED	R	0h	
24	CLEV	R	0h	mmc_cmd line signal level. This status is used to check the mmc_cmd line level to recover from errors, and for debugging. The value of this register after reset depends on the mmc_cmd line level at that time. 0h (R/W) = The mmc_cmd line level is 0. 1h (R/W) = The mmc_cmd line level is 1.
23-20	DLEV	R	0h	mmc_dat [3:0] line signal level mmc_dat3 equal to or greater than bit 23. mmc_dat2 equal to or greater than bit 22. mmc_dat1 equal to or greater than bit 21. mmc_dat0 equal to or greater than bit 20. This status is used to check mmc_dat line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from mmc_dat0 . The value of these registers after reset depends on the mmc_dat lines level at that time.
19	WP	R	0h	Write Protect. MMC/SD/SDIO1 only. SDIO cards only. This bit reflects the write protect input pin (SDWP) level. The value of this register after reset depends one the protect input pin (SDWP) level at that time. 0h (R/W) = If SD_CON[8] WPP is cleared to 0 (default), the card is write protected, otherwise the card is not write protected. 1h (R/W) = If SD_CON[8] WPP is cleared to 0 (default), the card is not write protected, otherwise the card is write protected.

Table 17-35. SD_PSTATE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18	CDPL	R	0h	Card Detect Pin Level. MMC/SD/SDIO1 only. SDIO cards only. This bit reflects the inverse value of the card detect input pin (SDCD). Debouncing is not performed on this bit and is valid only when Card State is stable. (SD_PSTATE[17] is set to 1). This bit must be debounced by software. The value of this register after reset depends on the card detect input pin (SDCD) level at that time. 0h (R/W) = The value of the card detect input pin (SDCD) is 1. 1h (R/W) = The value of the card detect input pin (SDCD) is 0.
17	CSS	R	0h	Card State Stable. This bit is used for testing. It is set to 1 only when Card Detect Pin Level is stable (SD_PSTATE[18] CPDL). Debouncing is performed on the card detect input pin (SDCD) to detect card stability. This bit is not affected by software reset. 0h (R/W) = Reset or Debouncing. 1h (R/W) = Reset or Debouncing.
16	CINS	R	0h	Card inserted. This bit is the debounced value of the card detect input pin (SDCD). An inactive to active transition of the card detect input pin (SDCD) will generate a card insertion interrupt (SD_STAT[CINS]). A active to inactive transition of the card detect input pin (SDCD) will generate a card removal interrupt (SD_STAT[REM]). This bit is not affected by a software reset. 0h (R/W) = If SD_CON[CDP] is cleared to 0 (default), no card is detected. The card may have been removed from the card slot. If SD_CON[CDP] is set to 1, the card has been inserted. 1h (R/W) = If SD_CON[CDP] is cleared to 0 (default), the card has been inserted from the card slot. If SD_CON[CDP] is set to 1, no card is detected. The card may have been removed from the card slot.
15-12	RESERVED	R	0h	
11	BRE	R	0h	Buffer read enable. This bit is used for non-DMA read transfers. It indicates that a complete block specified by SD_BLK [10:0] BLEN bits has been written in the buffer and is ready to be read. It is cleared to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (SD_STAT[5] BRR bit). 0h (R/W) = Read BLEN bytes disable 1h (R/W) = Read BLEN bytes enable. Readable data exists in the buffer.
10	BWE	R	0h	Buffer Write enable. This status is used for non-DMA write transfers. It indicates if space is available for write data. 0h (R/W) = There is no room left in the buffer to write BLEN bytes of data. 1h (R/W) = There is enough space in the buffer to write BLEN bytes of data.

Table 17-35. SD_PSTATE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
9	RTA	R	0h	Read transfer active. This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (SD_HCTL[17] CR bit) following a stop at block gap request. This bit is cleared to 0 when all data have been read by the local host after last block or after a stop at block gap request. 0h (R/W) = No valid data on the mmc_dat lines. 1h (R/W) = Read data transfer on going.
8	WTA	R	0h	Write transfer active. This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (SD_HCTL[17] CR bit) following a stop at block gap request. This bit is cleared to 0 when CRC status has been received after last block or after a stop at block gap request. 0h (R/W) = No valid data on the mmc_dat lines. 1h (R/W) = Write data transfer on going.
7-3	RESERVED	R	0h	
2	DLA	R	0h	mmc_dat line active. This status bit indicates whether one of the mmc_dat lines is in use. In the case of read transactions (card to host)This bit is set to 1 after the end bit of read command or by activating continue request SD_HCTL[17] CR bit. This bit is cleared to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card)This bit is set to 1 after the end bit of write command or by activating continue request SD_HCTL[17] CR bit. This bit is cleared to 0 on the end of busy event for the last block. The host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request. 0h (R/W) = mmc_dat line inactive 1h (R/W) = mmc_dat line active
1	DATI	R	0h	Command inhibit (mmc_dat). This status bit is generated if either mmc_dat line is active (SD_PSTATE[2] DLA bit) or Read transfer is active (SD_PSTATE[9] RTA bit) or when a command with busy is issued. This bit prevents the local host to issue a command. A change of this bit from 1 to 0 generates a transfer complete interrupt (SD_STAT[1] TC bit). 0h (R/W) = Issuing of command using the mmc_dat lines is allowed 1h (R/W) = Issuing of command using mmc_dat lines is not allowed
0	CMDI	R	0h	Command inhibit(mmc_cmd). This status bit indicates that the mmc_cmd line is in use. This bit is cleared to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted. This bit is cleared to 0 in either the following cases: After the end bit of the command response, excepted if there is a command conflict error (SD_STAT[17] CCRC bit or SD_STAT[18] CEB bit set to 1) or a Auto CMD12 is not executed (SD_AC12[0] ACNE bit). After the end bit of the command without response (SD_CMD [17:16] RSP_TYPE bits set to "00"). In case of a command data error is detected (SD_STAT[19] CTO bit set to 10, this register is not automatically cleared. 0h (R/W) = Issuing of command using mmc_cmd line is allowed 1h (R/W) = Issuing of command using mmc_cmd line is not allowed

17.5.1.17 SD_HCTL Register (Offset = 228h) [reset = 0h]

SD_HCTL is shown in Figure 17-53 and described in Table 17-36.

Return to Summary Table.

This register defines the host controls to set power, wake-up and transfer parameters. SD_HCTL[31:24] = Wake-up control. SD_HCTL[23:16] = Block gap control. SD_HCTL[15:8] = Power control. SD_HCTL[7:0] = Host control. If your device does not support MMC cards, then those bits in this register which are meant for MMC card use should be assumed to be reserved.

Table 17-36. SD_HCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-28	RESERVED	R	0h	
27	OBWE	R/W	0h	Wake-up event enable for 'out-of-band' Interrupt. This bit enables wake-up events for 'out-of-band' assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit). The write to this register is ignored when SD_CON[14] OBIE bit is not set. 0h (R/W) = Disable wake-up on 'out-of-band' Interrupt 1h (R/W) = Enable wake-up on 'out-of-band' Interrupt
26	REM	R/W	0h	Wake-up event enable on SD card removal. This bit enables wake-up events for card removal assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit). 0h (R/W) = Disable wake-up on card removal 1h (R/W) = Enable wake-up on card removal
25	INS	R/W	0h	Wake-up event enable on SD card insertion This bit enables wake-up events for card insertion assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit). 0h (R/W) = Disable wake-up on card insertion 1h (R/W) = Enable wake-up on card insertion
24	IWE	R/W	0h	Wake-up event enable on SD card interrupt. This bit enables wake-up events for card interrupt assertion. Wake-up is generated if the wake-up feature is enabled (SD_SYSCONFIG[2] ENAWAKEUP bit) and enable status bit is set (SD_IE[8] CIRQ_ENABLE bit). 0h (R/W) = Disable wake-up on card interrupt 1h (R/W) = Enable wake-up on card interrupt
23-20	RESERVED	R	0h	

Table 17-36. SD_HCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19	IBG	R/W	0h	Interrupt block at gap. This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be cleared to 0. 0h (R/W) = Disable interrupt detection at the block gap in 4-bit mode 1h (R/W) = Enable interrupt detection at the block gap in 4-bit mode
18	RWC	R/W	0h	Read wait control. The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (SD_HCTL[16] SBGR bit) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on mmc_dat line. 0h (R/W) = Disable read wait control. Suspend/resume cannot be supported. 1h (R/W) = Enable read wait control
17	CR	R/W	0h	Continue request. This bit is used to restart a transaction that was stopped by requesting a stop at block gap (SD_HCTL[16] SBGR bit). Set this bit to 1 restarts the transfer. The bit is automatically cleared to 0 by the host controller when transfer has restarted, that is, mmc_dat line is active (SD_PSTATE[2] DLA bit) or transferring data (SD_PSTATE[8] WTA bit). The Stop at block gap request must be disabled (SD_HCTL[16] SBGR bit =0) before setting this bit. 0h (R/W) = No affect 1h (R/W) = Transfer restart
16	SBGR	R/W	0h	Stop at block gap request. This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (SD_HCTL[17] CR bit) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (SD_STAT[1] TC bit set to 1), the host driver shall leave this bit set to 1.If this bit is set, the local host shall not write to the data register (SD_DATA). 0h (R/W) = Transfer mode 1h (R/W) = Stop at block gap
15-12	RESERVED	R	0h	
11-9	SDVS	R/W	0h	SD bus voltage select (All cards). The host driver should set these bits to select the voltage level for the card according to the voltage supported by the system (SD_CAPA[26] VS18 bit, SD_CAPA[25] VS30 bit, SD_CAPA[24] VS33 bit) before starting a transfer. If MMCSD 2: This field must be set to 5h. If MMCSD 3: This field must be set to 5h. 5h (R/W) = 1.8 V (Typical) 6h (R/W) = 3.0 V (Typical) 7h (R/W) = 3.3 V (Typical)

Table 17-36. SD_HCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	SDBP	R/W	0h	SD bus power. Before setting this bit, the host driver shall select the SD bus voltage (SD_HCTL [11:9] SDVS bits). If the host controller detects the No card state, this bit is automatically cleared to 0. It will not automatically change to 1 if the card is inserted. This needs to be done with software. If the module is power off, a write in the command register (SD_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage is not supported according to capability register (SD_CAPA[VS*]). 0h (R/W) = Power off 1h (R/W) = Power on
7	CDSS	R/W	0h	Card Detect Signal Selection. This bit selects source for the card detection. When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupt being caused by the glitch. The Interrupt Status/Signal Enable should be disabled during over the period of debouncing. 0h (R/W) = SDCD# is selected (for normal use). 1h (R/W) = The Card Detect Test Level is selected (for test purposes).
6	CDTL	R/W	0h	Card Detect Test Level. This bit is enabled while the Card Detect Signal Selection is set to 1 and it indicates card inserted or not. 0 = No card 1 = Card inserted.
5	RESERVED	R	0h	
4-3	DMAS	R/W	0h	DMA Select. One of the supported DMA modes can be selected. The host driver shall check support of DMA modes by referencing the Capabilities register. Use of selected DMA is determined by DMA Enable of the Transfer Mode register. This register is only meaningful when MADMA_EN is set to 1. When MADMA_EN is cleared to 0 the bit field is read only and returned value is 0. 0h (R/W) = Reserved 1h (R/W) = Reserved 2h (R/W) = 32-bit Address ADMA2 is selected. 3h (R/W) = Reserved
2	HSPE	R/W	0h	High Speed Enable. Before setting this bit, the Host Driver shall check the High Speed Support in the Capabilities register. If this bit is cleared to 0 (default), the Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock. If this bit is set to 1, the Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock. This bit shall not be set when dual data rate mode is activated in SD_CON[DDR]. 0h (R/W) = Normal speed mode 1h (R/W) = High speed mode
1	DTW	R/W	0h	Data transfer width. This bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card. 0h (R/W) = 1-bit Data width (mmc_dat0 used) 1h (R/W) = 4-bit Data width (mmc_dat[3:0] used)
0	RESERVED	R	0h	

17.5.1.18 SD_SYSCTL Register (Offset = 22Ch) [reset = 0h]

SD_SYSCTL is shown in Figure 17-54 and described in Table 17-37.

Return to Summary Table.

This register defines the system controls to set software resets, clock frequency management and data timeout. SD_SYSCTL[31:24] = Software resets. SD_SYSCTL[23:16] = Timeout control. SD_SYSCTL[15:0] = Clock control.

Table 17-37. SD_SYSCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
31-27	RESERVED	R	0h	
26	SRD	R/W	0h	Software reset for mmc_dat line. This bit is set to 1 for reset and released to 0 when completed. Due to additional implementation logic, the reset does not immediately start when asserted. The proper procedure is: (a) Set to 1 to start reset, (b) Poll for 1 to identify start of reset, and (c) Poll for 0 to identify reset is complete. mmc_dat finite state machine in both clock domain are also reset. These registers are cleared by the SD_SYSCTL[26] SRD bit: SD_DATA. SD_PSTATEBRE, BWE, RTA, WTA, DLA and DATI. SD_HCTLSBGR and CR. SD_STATBRR, BWR, BGE and TC Interconnect and MMC buffer data management is reinitialized. Note: If a soft reset is issued when an interrupt is asserted, data may be lost. 0h (R/W) = Reset completed 1h (R/W) = Software reset for mmc_dat line
25	SRC	R/W	0h	Software reset for mmc_cmd line. This bit is set to 1 for reset and released to 0 when completed. Due to additional implementation logic, the reset does not immediately start when asserted. The proper procedure is: (a) Set to 1 to start reset, (b) Poll for 1 to identify start of reset, and (c) Poll for 0 to identify reset is complete. mmc_cmd finite state machine in both clock domain are also reset. These registers are cleared by the SD_SYSCTL[25] SRC bit: SD_PSTATECMDI. SD_STATCC Interconnect and MMC command status management is reinitialized. Note: If a soft reset is issued when an interrupt is asserted, data may be lost. 0h (R/W) = Reset completed 1h (R/W) = Software reset for mmc_cmd line
24	SRA	R/W	0h	Software reset for all. This bit is set to 1 for reset , and released to 0 when completed. This reset affects the entire host controller except for the card detection circuit and capabilities registers. 0h (R/W) = Reset completed 1h (R/W) = Software reset for all the design
23-20	RESERVED	R	0h	

Table 17-37. SD_SYSCTL Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
19-16	DTO	R/W	0h	Data timeout counter value and busy timeout. This value determines the interval by which mmc_dat lines timeouts are detected. The host driver needs to set this bit field based on: The maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer). The data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card. The timeout clock base frequency (SD_CAPA [5:0] TCF bits). If the card does not respond within the specified number of cycles, a data timeout error occurs (SD_STAT[20] DTO bit). The SD_SYSCTL[19,16] DTO bit field is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write. 0h (R/W) = TCF x 2^{13} 1h (R/W) = TCF x 2^{14} Eh (R/W) = TCF x 2^{27} Fh (R/W) = Reserved
15-6	CLKD	R/W	0h	Clock frequency select. These bits define the ratio between a reference clock frequency (system dependant) and the output clock frequency on the mmc_clk pin of either the memory card (MMC, SD, or SDIO). 0h (R/W) = Clock Ref bypass 1h (R/W) = Clock Ref bypass 2h (R/W) = Clock Ref / 2 3h (R/W) = Clock Ref / 3 3FFh (R/W) = Clock Ref / 1023
5-3	RESERVED	R	0h	
2	CEN	R/W	0h	Clock enable. This bit controls if the clock is provided to the card or not. 0h (R/W) = The clock is not provided to the card . Clock frequency can be changed . 1h (R/W) = The clock is provided to the card and can be automatically gated when SD_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value). The host driver shall wait to set this bit to 1 until the Internal clock is stable (SD_SYSCTL[1] ICS bit).
1	ICS	R	0h	Internal clock stable (status)This bit indicates either the internal clock is stable or not. 0h (R/W) = The internal clock is not stable. 1h (R/W) = The internal clock is stable after enabling the clock (SD_SYSCTL[0] ICE bit) or after changing the clock ratio (SD_SYSCTL[15:6] CLKD bits).
0	ICE	R/W	0h	Internal clock enable. This register controls the internal clock activity. In very low power state, the internal clock is stopped. Note: The activity of the debounce clock (used for wake-up events) and the interface clock (used for reads and writes to the module register map) are not affected by this register. 0h (R/W) = The internal clock is stopped (very low power state). 1h (R/W) = The internal clock oscillates and can be automatically gated when SD_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value).

17.5.1.19 SD_STAT Register (Offset = 230h) [reset = 0h]

SD_STAT is shown in Figure 17-55 and described in Table 17-38.

Return to Summary Table.

The interrupt status regroups all the status of the module internal events that can generate an interrupt. SD_STAT[31:16] = Error Interrupt Status. SD_STAT[15:0] = Normal Interrupt Status. The error bits are located in the upper 16 bits of the SD_STAT register. All bits are cleared by writing a 1 to them. Additionally, bits 15 and 8 serve as special error bits. These cannot be cleared by writing a 1 to them. Bit 15 (ERRI) is automatically cleared when the error causing to ERRI to be set is handled. (that is, when bits 31:16 are cleared, bit 15 will be automatically cleared). Bit 8 (CIRQ) is cleared by writing a 0 to SD_IE[8] (masking the interrupt) and servicing the interrupt.

Table 17-38. SD_STAT Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	RESERVED	R	0h	
29	BADA	R/W	0h	Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: During a read access to the data register (SD_DATA) while buffer reads are not allowed (SD_PSTATE[11] BRE bit =0). During a write access to the data register (SD_DATA) while buffer writes are not allowed (SD_PSTATE[10] BWE bit=0). 0h (W) = Status bit unchanged 0h (R) = No interrupt 1h (W) = Status is cleared. 1h (R) = Bad access
28	CERR	R/W	0h	Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E (error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error SD_CSRE in set. There is no card error detection for autoCMD12 command. The host driver shall read SD_RSP76 register to detect error bits in the command response. 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Card error
27-26	RESERVED	R	0h	

Table 17-38. SD_STAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
25	ADMAE	R/W	0h	ADMA Error. This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the Host Controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor. 0h (W) = Status bit unchanged 0h (R) = No interrupt 1h (W) = Status is cleared. 1h (R) = ADMA error
24	ACE	R/W	0h	Auto CMD12 error. This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1. 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = AutoCMD12 error
23	RESERVED	R	0h	
22	DEB	R/W	0h	Data End Bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on mmc_dat line or at the end position of the CRC status in write mode. 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Data end bit error
21	DCRC	R/W	0h	Data CRC Error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command. 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Data CRC error
20	DTO	R/W	0h	Data timeout error. This bit is set automatically according to the following conditions: Busy timeout for R1b, R5b response type. Busy timeout after write CRC status. Write CRC status timeout. Read data timeout. 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Time out
19	CIE	R/W	0h	Command index error. This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable bit (SD_CMD[20] CICE). 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Command index error

Table 17-38. SD_STAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
18	CEB	R/W	0h	Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response. 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Command end bit error
17	CCRC	R/W	0h	Command CRC error. This bit is set automatically when there is a CRC7 error in the command response depending on the enable bit (SD_CMD[19] CCCE). 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Command CRC error
16	CTO	R/W	0h	Command timeout error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles. 0h (W) = Status bit unchanged 0h (R) = No error 1h (W) = Status is cleared. 1h (R) = Time Out
15	ERRI	R	0h	Error interrupt. If any of the bits in the Error Interrupt Status register (SD_STAT [31:16]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored. 0h (R/W) = No interrupt 1h (R/W) = Error interrupt event(s) occurred
14-11	RESERVED	R	0h	
10	BSR	R/W	0h	Boot Status Received Interrupt. This bit is set automatically when SD_CON[BOOT] is set 1 or 2 and a boot status is received on DAT[0] line. This interrupt is only useful for MMC card. 0h (W) = Status bit unchanged 0h (R) = No interrupt 1h (W) = Status is cleared. 1h (R) = Boot Status Received Interrupt occurred.
9	OBI	R	0h	Out-of-band interrupt (This interrupt is only useful for MMC card). This bit is set automatically when SD_CON[14] OBIE bit is set and an out-of-band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by SD_CON[13] OBIP bit. The out-of-band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation. 0h (W) = Status bit unchanged 0h (R) = No out-of-band interrupt 1h (W) = Status is cleared. 1h (R) = Interrupt out-of-band occurs

Table 17-38. SD_STAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	CIRQ	R	0h	Card interrupt. This bit is only used for SD and SDIO cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wake-up). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drives mmc_cmd line to zero during one cycle after data transmission end. All modes above are fully exclusive. The controller interrupt must be clear by setting SD_IE[8] CIRQ_ENABLE to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as SD_IE[8] CIRQ_ENABLE is set to 1. Writes to this bit are ignored. 0h (R/W) = No card interrupt 1h (R/W) = Generate card interrupt
7	CREM	R/W	0h	Card Removal. This bit is set automatically when SD_PSTATE[CINS] changes from 1 to 0. A clear of this bit doesn't affect Card inserted present state (SD_PSTATE[CINS]). 0h (W) = Status bit unchanged 0h (R) = Card State stable or debouncing 1h (R) = Card Removed 1h (W) = Status is cleared
6	CINS	R/W	0h	Card Insertion. This bit is set automatically when SD_PSTATE[CINS] changes from 0 to 1. A clear of this bit doesn't affect Card inserted present state (SD_PSTATE[CINS]). 0h (W) = Status bit unchanged 0h (R) = Card State stable or debouncing 1h (W) = Status is cleared. 1h (R) = Card inserted
5	BRR	R/W	0h	Buffer read ready. This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by the SD_BLK [10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it. Note: If the DMA receive-mode is enabled, this bit is never set instead a DMA receive request to the main DMA controller of the system is generated. 0h (W) = Status bit unchanged 0h (R) = Not ready to read buffer 1h (W) = Status is cleared. 1h (R) = Ready to read buffer

Table 17-38. SD_STAT Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
4	BWR	R/W	0h	Buffer write ready. This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by SD_BLK [10:0] BLEN. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer. Note: If the DMA transmit mode is enabled, this bit is never set instead, a DMA transmit request to the main DMA controller of the system is generated. 0h (W) = Status bit unchanged 0h (R) = Not ready to write buffer 1h (W) = Status is cleared. 1h (R) = Ready to write buffer
3	DMA	R/W	0h	DMA Interrupt. This status is set when an interrupt is required in the ADMA instruction and after the data transfer completion. 0h (W) = Status bit unchanged 0h (R) = DMA Interrupt detected 1h (W) = Status is cleared. 1h (R) = No DMA Interrupt
2	BGE	R/W	0h	Block gap event. When a stop at block gap is requested (SD_HCTL[16] SBGR bit), this bit is automatically set when transaction is stopped at the block gap during a read or write operation. 0h (W) = Status bit unchanged 0h (R) = No block gap event 1h (R) = Transaction stopped at block gap 1h (W) = Status is cleared
1	TC	R/W	0h	Transfer completed. This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (SD_HCTL[16] SBGR bit). 0h (W) = Status bit unchanged 0h (R) = No transfer complete 1h (W) = Status is cleared 1h (R) = Data transfer complete
0	CC	R/W	0h	Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (SD_PSTATE[0] CMDI bit) 0h (W) = Status bit unchanged 0h (R) = No command complete 1h (W) = Status is cleared 1h (R) = Command complete

17.5.1.20 SD_IE Register (Offset = 234h) [reset = 0h]

SD_IE is shown in Figure 17-56 and described in Table 17-39.

Return to Summary Table.

This register allows to enable/disable the module to set status bits, on an event-by-event basis. SD_IE[31:16] = Error Interrupt Status Enable. SD_IE[15:0] = Normal Interrupt Status Enable.

15	NULL	R	0h	Fixed to 0. The host driver shall control error interrupts using the error interrupt signal enable register. Writes to this bit are ignored.
14-11	RESERVED	R	0h	
10	BSR_SIGEN	R/W	0h	Boot Status signal status enable. A write to this register when SD_CON[BOOT] is cleared to 0 is ignored 0h (R/W) = Masked 1h (R/W) = Enabled
9	OBI_SIGEN	R/W	0h	Out-of-band interrupt signal status enable. A write to this register when SD_CON[14] OBIE is cleared to 0 is ignored. 0h (R/W) = Masked 1h (R/W) = Enabled
8	CIRQ_SIGEN	R/W	0h	Card interrupt signal status enable. A clear of this bit also clears the corresponding status bit. During 1-bit mode, if the interrupt routine does not remove the source of a card interrupt in the SDIO card, the status bit is reasserted when this bit is set to 1. This bit must be set to 1 when entering in smart idle mode to enable system to identity wake-up event and to allow controller to clear internal wake-up source. 0h (R/W) = Masked 1h (R/W) = Enabled
7	CREM_SIGEN	R/W	0h	Card Removal signal status enable This bit must be set to 1 when entering in smart idle mode to enable system to identity wake-up event and to allow controller to clear internal wake-up source. 0h (R/W) = Masked 1h (R/W) = Enabled
6	CINS_SIGEN	R/W	0h	Card Insertion signal status enable. This bit must be set to 1 when entering in smart idle mode to enable system to identity wake-up event and to allow controller to clear internal wake-up source. 0h (R/W) = Masked 1h (R/W) = Enabled
5	BRR_SIGEN	R/W	0h	Buffer read ready signal status enable 0h (R/W) = Masked 1h (R/W) = Enabled
4	BWR_SIGEN	R/W	0h	Buffer write ready signal status enable 0h (R/W) = Masked 1h (R/W) = Enabled
3	DMA_SIGEN	R/W	0h	DMA signal status enable 0h (R/W) = Masked 1h (R/W) = Enabled

Table 17-40. SD_ISE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
2	BGE_SIGEN	R/W	0h	Block gap event signal status enable 0h (R/W) = Masked 1h (R/W) = Enabled
1	TC_SIGEN	R/W	0h	Transfer completed signal status enable 0h (R/W) = Masked 1h (R/W) = Enabled
0	CC_SIGEN	R/W	0h	Command completed signal status enable 0h (R/W) = Masked 1h (R/W) = Enabled

17.5.1.22 SD_AC12 Register (Offset = 23Ch) [reset = 0h]

SD_AC12 is shown in Figure 17-58 and described in Table 17-41.

Return to Summary Table.

The host driver may determine which of the errors cases related to Auto CMD12 has occurred by checking this SD_AC12 register when an auto CMD12 error interrupt occurs. This register is valid only when auto CMD12 is enabled (SD_CMD[2] ACEN bit) and auto CMD12Error (SD_STAT[24] ACE bit) is set to 1. These bits are automatically reset when starting a new adtc command with data.

28	BUS_64BIT	R/W	0h	64 Bit System Bus Support. Setting 1 to this bit indicates that the Host Controller supports 64-bit address descriptor mode and is connected to 64-bit address system bus. 0h (R/W) = 32-bit System bus address 1h (R/W) = 64-bit System bus address
27	RESERVED	R	0h	
26	VS18	R/W	0h	Voltage support 1.8 V. Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via mmc_RESET signal). 0h (W) = 1.8 V not supported 0h (R) = 1.8 V not supported 1h (R) = 1.8 V supported 1h (W) = 1.8 V supported
25	VS30	R/W	0h	Voltage support 3.0V. Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via mmc_RESET signal). 0h (W) = 3.0 V not supported 0h (R) = 3.0 V not supported 1h (R) = 3.0 V supported 1h (W) = 3.0 V supported

Table 17-42. SD_CAPA Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
24	VS33	R/W	0h	Voltage support 3.3V. Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via mmc_RESET signal). 0h (W) = 3.3 V not supported 0h (R) = 3.3 V not supported 1h (R) = 3.3 V supported 1h (W) = 3.3 V supported
23	SRS	R	0h	Suspend/resume support (SDIO cards only). This bit indicates whether the host controller supports Suspend/Resume functionality. 0h (R/W) = The Host controller does not suspend/resume functionality. 1h (R/W) = The Host controller supports suspend/resume functionality.
22	DS	R	0h	DMA support. This bit indicates that the Host controller is able to use DMA to transfer data between system memory and the Host controller directly. 0h (R/W) = DMA not supported 1h (R/W) = DMA supported
21	HSS	R	0h	High-speed support. This bit indicates that the host controller supports high speed operations and can supply an up-to-52 MHz clock to the card. 0h (R/W) = DMA not supported 1h (R/W) = DMA supported
20	RESERVED	R	0h	
19	AD2S	R	0h	This bit indicates whether the Host Controller is capable of using ADMA2. It depends on setting of generic parameter MADMA_EN. 0h (R/W) = ADMA2 supported 1h (R/W) = ADMA2 not supported
18	RESERVED	R	0h	
17-16	MBL	R	0h	Maximum block length. This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. The host controller supports 512 bytes and 1024 bytes block transfers. 0h (R/W) = 512 bytes 1h (R/W) = 1024 bytes 2h (R/W) = 2048 bytes
15-14	RESERVED	R	0h	
13-8	BCF	R	0h	Base clock frequency for clock provided to the card. ARRAY(0x1bfe1b0)
7	TCU	R	0h	Timeout clock unit. This bit shows the unit of base clock frequency used to detect Data Timeout Error (SD_STAT[20] DTO bit). 0h (R/W) = kHz 1h (R/W) = MHz
6	RESERVED	R	0h	
5-0	TCF	R	0h	Timeout clock frequency. The timeout clock frequency is used to detect Data Timeout Error (SD_STAT[20] DTO bit). 0h (R/W) = The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register.

17.5.1.24 SD_CUR_CAPA Register (Offset = 248h) [reset = 0h]

SD_CUR_CAPA is shown in Figure 17-60 and described in Table 17-43.

Return to Summary Table.

This register indicates the maximum current capability for each voltage. The value is meaningful if the voltage support is set in the capabilities register (SD_CAPA). Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via mmc_RESET signal).

17.5.1.26 SD_ADMAES Register (Offset = 254h) [reset = 0h]

SD_ADMAES is shown in Figure 17-62 and described in Table 17-45.

Return to Summary Table.

When an ADMA Error Interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. For recovering the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows: ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address. ST_FDS: Current location set in the ADMA System Address register is the error descriptor address. ST_CADR: This sate is never set because do not generate ADMA error in this state. ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address. In the case of a write operation, the Host Driver should use ACMD22 to get the number of written block rather than using this information, since unwritten data may exist in the Host Controller. The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid = 0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.

2	LME	W	0h	ADMA Length Mismatch Error: While Block Count Enable is being set, the total data length specified by the Descriptor table is different from that specified by the Block Count and Block Length. Total data length cannot be divided by the block length. 0h (R/W) = No error 1h (R/W) = Error
1-0	AES	R/W	0h	ADMA Error State. This field indicates the state of ADMA when an error occurred during an ADMA data transfer. This field never indicates "10" because ADMA never stops in this state. 0h (R) = ST_STOP (Stop DMA). Contents of the SYS_SDR register 1h (W) = ST_STOP (Stop DMA). Points to the error descriptor. 2h (R) = Never set this state. (Not used) 3h (W) = ST_TFR (Transfer Data). Points to the 'next' of the error descriptor.

17.5.1.27 SD_ADMASAL Register (Offset = 258h) [reset = 0h]

SD_ADMASAL is shown in Figure 17-63 and described in Table 17-46.

Return to Summary Table.

This register holds the byte address of the executing command of the Descriptor table. The 32-bit Address Descriptor uses the lower 32 bits of this register. At the start of ADMA, the Host Driver shall set the start address of the Descriptor table.

Figure 17-63. SD_ADMASAL Register

Bit	Field	Type	Reset	Description
31-24	VREV	R	0h	Vendor Version Number. Bits [7:4] is the major revision, bits [3:0] is the minor revision. Examples: 10h for 1.0 21h for 2.1
23-16	SREV	R	0h	Specification Version Number. This status indicates the Standard SD Host Controller Specification Version. The upper and lower 4-bits indicate the version. 0h (R/W) = SD Host Specification Version 1.0
15-1	RESERVED	R	0h	
0	SIS	R	0h	Slot Interrupt Status. This status bit indicates the inverted state of interrupt signal for the module. By a power on reset or by setting a software reset for all (SD_SYSCTL[24] SRA), the interrupt signal shall be deasserted and this status shall read 0. 0h = Interrupt signal deasserted. 1h = Interrupt signal asserted.

Interprocessor Communication

This chapter describes the interprocessor communication of the device.

18.1 Mailbox

18.1.1 Introduction

18.1.1.1 Features

Global features of the Mailbox module are:

- OCP slave interface (L4) supports:
  - 32-bit data bus width
  - 8/16/32 bit access supported
  - 9-bit address bus width
  - Burst not supported
- 8 mailbox sub-modules
- Each mailbox sub module allows 1-way communication between 2 initiators
- Flexible mailbox/initiators assignment scheme
- 4 messages per mailbox sub-module
- 32-bit message width
- Support of 16/32-bit addressing scheme
- Non-intrusive emulation
- 4 interrupts (one per user: 1 to MPU Subsystem, 2 to PRU-ICSS, and 1 to Wakeup Processor)

18.1.1.2 Unsupported Features

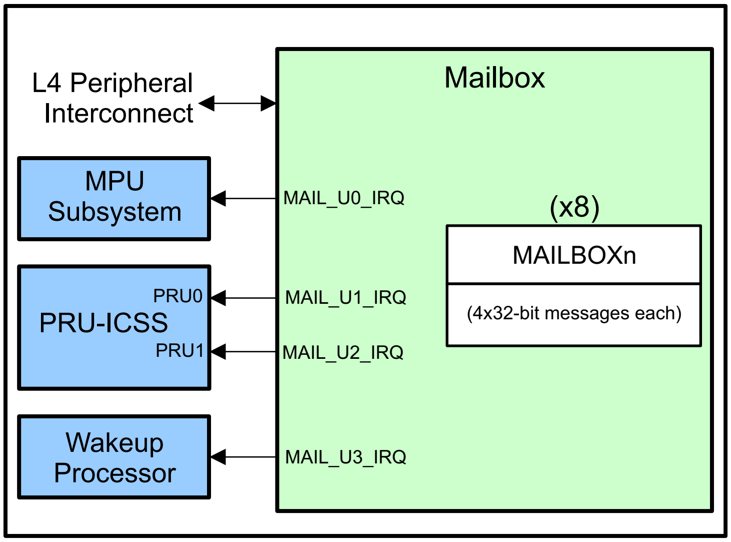
There are no unsupported features for Mailbox on this device.

18.1.2 Integration

This device contains a single instantiation of the Mailbox module at the system level. The mailbox function is made of eight sub-module mailboxes each supporting a 1-way communication between two initiators. The communication protocol from the sender to the receiver is implemented with mailbox registers using interrupts. The sender sends information to the receiver by writing to the mailbox. Interrupt signaling is used to notify the receiver a message has been queued or the sender for overflow situation.

The eight mailboxes are enough to handle communications between the MPU Subsystem, PRU-ICSS PRUs, and Wakeup Processor. Note that because the Wakeup Processor has access to only L4_Wakeup peripherals it does not have access to the Mailbox registers. A mailbox interrupt can still be sent to the Wakeup Processor to trigger message notification. The actual message payload must be placed in either the internal memory of the Wakeup Processor or in the Control Module Interprocessor Message registers (IPC_MSG_REG{0-15}).

Figure 18-1. Mailbox Integration



18.1.2.1 Mailbox Connectivity Attributes

The general connectivity for the Mailbox is shown in Table 18-1.

Table 18-1. Mailbox Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	L4PER_L4LS_GCLK
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	4 Interrupts mail_u0 (MBINT0) – to MPU Subsystem mail_u1 – to PRU-ICSS (PRU0) mail_u2 – to PRU-ICSS (PRU1) mail_u3 – to Wakeup Processor
DMA Requests	None
Physical Address	L4 Peripheral slave port

18.1.2.2 Mailbox Clock and Reset Management

The mailbox function operates from the L4 interface clock.

Table 18-2. Mailbox Clock Signals

Functional / Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk From PRCM

18.1.2.3 Mailbox Pin List

The Mailbox module does not include any external interface pins.

18.1.3 Functional Description

This device has the following mailbox instances:

- System mailbox

Table 18-3 shows Mailbox Implementation in this device, where u is the user number and m is the mailbox number.

Table 18-3. Mailbox Implementation

Mailbox Type	User Number(u)	Mailbox Number(m)	Messages per Mailbox
System mailbox	0 to 3	0 to 7	4

The mailbox module provides a means of communication through message queues among the users (depending on the mailbox module instance). The individual mailbox modules (8 for the system mailbox instance), or FIFOs, can associate (or de-associate) with any of the processors using the MAILBOX_IRQENABLE_SET_u (or MAILBOX_IRQENABLE_CLR_u) register.

The system mailbox module includes the following user subsystems:

- User 0: MPU Subsystem (u = 0)
- User 1: PRU_ICSS PRU0 (u = 1)
- User 2: PRU_ICSS PRU1 (u = 2)
- User 3: Wakeup Processor (u = 3)

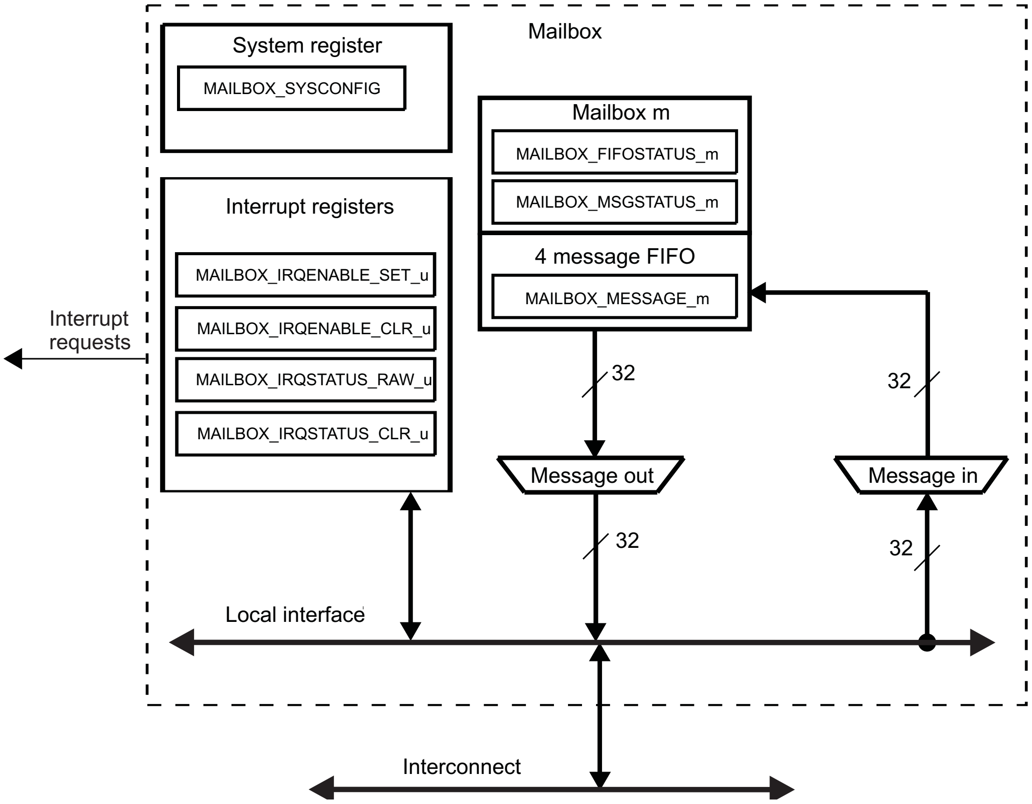
Each user has a dedicated interrupt signal from the corresponding mailbox module instance and dedicated interrupt enabling and status registers. Each MAILBOX_IRQSTATUS_RAW_u/MAILBOX_IRQSTATUS_CLR_u interrupt status register corresponds to a particular user.

For the system mailbox instance, a user can query its interrupt status register through the L4_STANDARD interconnect.

18.1.3.1 Mailbox Block Diagram

Figure 18-2 shows the mailbox block diagram.

Figure 18-2. Mailbox Block Diagram



18.1.3.2 Software Reset

The mailbox module supports a software reset through the MAILBOX_SYSCONFIG[0].SOFTRESET bit. Setting this bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Reading the MAILBOX_SYSCONFIG[0] SOFTRESET bit gives the status of the software reset:

- Read 1: the software reset is on-going
- Read 0: the software reset is complete

The software must ensure that the software reset completes before doing mailbox operations.

18.1.3.3 Power Management

Table 18-4 describes power-management features available for the mailbox module.

Table 18-4. Local Power Management Features

Feature	Registers	Description
Clock autogating	NA	Feature not available
Slave idle modes	MAILBOX_SYSCONFIG[3:2].SIDLEMODE	Force-idle, no-idle and smart-idle modes are available
Clock activity	NA	Feature not available
Master standby modes	NA	Feature not available
Global wake-up enable	NA	Feature not available
Wake-up sources enable	NA	Feature not available

The mailbox module can be configured using the MAILBOX_SYSCONFIG[3:2] SIDLEMODE bit field to one of the following acknowledgment modes:

- Force-idle mode (SIDLEMODE = 0x0): The mailbox module immediately enters the idle state on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state.
- No-idle mode (SIDLEMODE = 0x1): The mailbox module never enters the idle state.
- Smart-idle mode (SIDLEMODE = 0x2): After receiving a low-power-mode request from the PRCM module, the mailbox module enters the idle state only after all asserted output interrupts are acknowledged.

18.1.3.4 Interrupt Requests

An interrupt request allows the user of the mailbox to be notified when a message is received or when the message queue is not full. There is one interrupt per user. Table 18-5 lists the event flags, and their mask, that can cause module interrupts.

Table 18-5. Interrupt Events

Non-Maskable Event Flag[1]	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
MAILBOX_IRQSTATUS_RAW_u[0+m*2].NEWMSGSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[0+m*2].NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[0+m*2].		
MAILBOX_IRQSTATUS_RAW_u[0+m*2].NEWMSGSTATUSUUMBm	MAILBOX_IRQSTATUS_CLR_u[0+m*2].NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_CLR_u[0+m*2].NEWMSGSTATUSUUMBm	MAILBOX_IRQENABLE_SET_u[0+m*2].NEWMSGSTATUSUUMBm	Mailbox m receives a new message
MAILBOX_IRQSTATUS_RAW_u[1+m*2].NOTFULLSTATUSUMBm	MAILBOX_IRQSTATUS_CLR_u[1+m*2].NOTFULLSTATUSUMBm	MAILBOX_IRQENABLE_CLR_u[1+m*2].NOTFULLSTATUSUMBm	MAILBOX_IRQENABLE_SET_u[1+m*2].NOTFULLSTATUSUMBm	Mailbox m message queue is not full

(1) MAILBOX.MAILBOX_IRQSTATUS_RAW_u register is mostly used for debug purposes.

CAUTION

Once an event generating the interrupt request has been processed by the software, it must be cleared by writing a logical 1 in the corresponding bit of the MAILBOX_IRQSTATUS_CLR_u register. Writing a logical 1 in a bit of the MAILBOX_IRQSTATUS_CLR_u register will also clear to 0 the corresponding bit in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

An event can generate an interrupt request when a logical 1 is written to the corresponding unmask bit in the MAILBOX_IRQENABLE_SET_u register. Events are reported in the appropriate MAILBOX_IRQSTATUS_CLR_u and MAILBOX_IRQSTATUS_RAW_u registers.

An event stops generating interrupt requests when a logical 1 is written to the corresponding mask bit in the MAILBOX_IRQENABLE_CLR_u register. Events are only reported in the appropriate MAILBOX_IRQSTATUS_RAW_u register.

In case of the MAILBOX_IRQSTATUS_RAW_u register, the event is reported in the corresponding bit even if the interrupt request generation is disabled for this event.

18.1.3.5 Assignment

18.1.3.5.1 Description

To assign a receiver to a mailbox, set the new message interrupt enable bit corresponding to the desired mailbox in the MAILBOX_IRQENABLE_SET_u register. The receiver reads the MAILBOX_MESSAGE_m register to retrieve a message from the mailbox.

An alternate method for the receiver that does not use the interrupts is to poll the MAILBOX_FIFOSTATUS_m and/or MAILBOX_MSGSTATUS_m registers to know when to send or retrieve a message to or from the mailbox. This method does not require assigning a receiver to a mailbox. Because this method does not include the explicit assignment of the mailbox, the software must avoid having multiple receivers use the same mailbox, which can result in incoherency.

To assign a sender to a mailbox, set the queue-not-full interrupt enable bit of the desired mailbox in the MAILBOX_IRQENABLE_SET_u register, where u is the number of the sending user. However, direct allocation of a mailbox to a sender is not recommended because it can cause the sending processor to be constantly interrupted.

It is recommended that register polling be used to:

- Check the status of either the MAILBOX_FIFOSTATUS_m or MAILBOX_MSGSTATUS_m registers
- Write the message to the corresponding MAILBOX_MESSAGE_m register, if space is available

The sender might use the queue-not-full interrupt when the initial mailbox status check indicates the mailbox is full. In this case, the sender can enable the queue-not-full interrupt for its mailbox in the appropriate MAILBOX_IRQENABLE_SET_u register. This allows the sender to be notified by interrupt only when a FIFO queue has at least one available entry.

Reading the MAILBOX_IRQSTATUS_CLR_u register determines the status of the new message and the queue-not-full interrupts for a particular user. Writing 1 to the corresponding bit in the MAILBOX_IRQSTATUS_CLR_u register acknowledges, and subsequently clears, an interrupt.

CAUTION

Assigning multiple senders or multiple receivers to the same mailbox is not recommended.

18.1.3.6 Sending and Receiving Messages

18.1.3.6.1 Description

When a 32-bit message is written to the MAILBOX_MESSAGE_m register, the message is appended into the FIFO queue. This queue holds four messages. If the queue is full, the message is discarded. Queue overflow can be avoided by first reading the MAILBOX_FIFOSTATUS_m register to check that the mailbox message queue is not full before writing a new message to it. Reading the MAILBOX_MESSAGE_m register returns the message at the beginning of the FIFO queue and removes it from the queue. If the FIFO queue is empty when the MAILBOX_MESSAGE_m register is read, the value 0 is returned. The new message interrupt is asserted when at least one message is in the mailbox message FIFO queue. To determine the number of messages in the mailbox message FIFO queue, read the MAILBOX_MSGSTATUS_m register.

18.1.3.7 16-Bit Register Access

18.1.3.7.1 Description

So that 16-bit processors can access the mailbox module, the module allows 16-bit register read and write access, with restrictions for the MAILBOX_MESSAGE_m registers. The 16-bit half-words are organized in little endian fashion; that is, the least-significant 16 bits are at the low address and the most-significant 16 bits are at the high address (low address + 0x02). All mailbox module registers can be read or written to directly using individual 16-bit accesses with no restriction on interleaving, except the MAILBOX_MESSAGE_m registers, which must always be accessed by either single 32-bit accesses or two consecutive 16-bit accesses.

CAUTION

When using 16-bit accesses to the MAILBOX_MESSAGE_m registers, the order of access must be the least-significant half-word first (low address) and the most-significant half-word last (high address). This requirement is because of the update operation by the message FIFO of the MAILBOX_MSGSTATUS_m registers. The update of the FIFO queue contents and the associated status registers and possible interrupt generation occurs only when the most-significant 16 bits of a MAILBOX_MESSAGE_m are accessed.

18.1.4 Programming Guide

18.1.4.1 Low-level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the mailbox module.

18.1.4.1.1 Global Initialization

18.1.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the mailbox module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the mailbox.

See Section 18.1.2 for further information.

Table 18-6. Global Initialization of Surrounding Modules for System Mailbox

Surrounding Modules	Comments
PRCM	Mailbox functional/interface clock must be enabled.
Interrupt Controllers	MPU interrupt controller must be configured to enable the interrupt request generation to the MPU.

18.1.4.1.1.2 Mailbox Global Initialization

18.1.4.1.1.2.1 Main Sequence - Mailbox Global Initialization

This procedure initializes the mailbox module after a power-on or software reset.

Table 18-7. Mailbox Global Initialization

	Register/Bitfield/Programming Model	Value
Perform a software reset	MAILBOX_SYSCONFIG[0].SOFTRESET	1
Wait until reset is complete	MAILBOX_SYSCONFIG[0].SOFTRESET	0
Set idle mode configuration	MAILBOX_SYSCONFIG[3:2].SIDLEMODE	0x-

18.1.4.1.2 Operational Modes Configuration

18.1.4.1.2.1 Main Sequence - Sending a Message (Polling Method)

Table 18-8. Sending a Message (Polling Method)

Step	Register/Bitfield/Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0].FIFOFULLMB	=1h
Wait until at least one message slot is available	MAILBOX_FIFOSTATUS_m[0].FIFOFULLMB	=0h
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM	----h
ENDIF		

18.1.4.1.2.2 Main Sequence - Sending a Message (Interrupt Method)

Table 18-9. Sending a Message (Interrupt Method)

Step	Register/Bitfield/Programming Model	Value
IF : Is FIFO full ?	MAILBOX_FIFOSTATUS_m[0].FIFOFULLMB	=1h
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[1+ m*2]	1h
User(processor) can perform anothr task until interrupt occurs		
ELSE		
Write message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM	----h
ENDIF		

18.1.4.1.2.3 Main Sequence - Receiving a Message (Polling Method)

Table 18-10. Receiving a Message (Polling Method)

Step	Register/Bitfield/Programming Model	Value
IF : Number of messages is not equal to 0	MAILBOX_MSGSTATUS_m[2:0].NBOFMSGMB	!=0h
Read message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM	----h
ENDIF		

18.1.4.1.2.4 Main Sequence - Receiving a Message (Interrupt Method)

Table 18-11. Receiving a Message (Interrupt Method)

Step	Register/Bitfield/Programming Model	Value
Enable interrupt event	MAILBOX_IRQENABLE_SET_u[0 + m*2]	1h
User(processor) can perform anothr task until interrupt occurs		

18.1.4.1.3 Events Servicing

18.1.4.1.3.1 Sending Mode

Table 18-12 describes the events servicing in sending mode.

Table 18-12. Events Servicing in Sending Mode

Step	Register/Bitfield/Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	1
Write message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM	----h
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[1 + m*2]	1

18.1.4.1.3.2 Receiving Mode

Table 18-13 describes the events servicing in receiving mode.

Table 18-13. Events Servicing in Receiving Mode

Step	Register/Bitfield/Programming Model	Value
Read interrupt status bit	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	1
IF : Number of messages is not equal to 0 ?	MAILBOX_MSGSTATUS_m[2:0].NBOFMSGMB	!=0h
Read message	MAILBOX_MESSAGE_m[31:0].MESSAGEVALUEMBM	----h
ELSE		
Write 1 to acknowledge interrupt	MAILBOX_IRQSTATUS_CLR_u[0 + m*2]	1
ENDIF		

18.1.5 MAILBOX Registers

Table 18-14 lists the memory-mapped registers for the MAILBOX. All register offset addresses not listed in Table 18-14 should be considered as reserved locations and the register contents should not be modified.

18.1.5.41 MLB_IRQEN_SET_3 Register (offset = 138h) [reset = 0h]

Register mask: FFFFFFFFh

MLB_IRQEN_SET_3 is shown in Figure 18-43 and described in Table 18-55.

The interrupt enable register enables to unmask the module internal source of interrupt to the corresponding user. This register is write 1 to set.

18.2.1.1 SPINLOCK_REV Register (offset = 0h) [reset = 50020000h]

Register mask: FFFFFFFFh

SPINLOCK_REV is shown in Figure 18-45 and described in Table 18-58.

Read-only IP revision identifier (X.Y.R) used by software to determine features, bugs and compatibility of an instance of this the Spin Lock module.

Figure 18-45. SPINLOCK_REV Register

18.2.1.2 SPINLOCK_SYSCONFIG Register (offset = 10h) [reset = 11h]

Register mask: FFFFFFFFh

SPINLOCK_SYSCONFIG is shown in Figure 18-46 and described in Table 18-59.

This register controls the various parameters of the OCP interface. Note that several fields are present by read-only.

Bit	Field	Type	Reset	Description
31-9	RESERVED	R	0h	
8	CLOCKACTIVITY	R	0h	Indicates whether the module requires the OCP when in IDLE mode. 0h = OCP clock is not required by the module during IDLE mode and may be switched off. 1h = OCP clock is required by the module, even during idle mode.
7-5	RESERVED	R	0h	
4-3	SIDLEMODE	R	2h	Control of the slave interface power management IDLE request acknowledgement. 0h = IDLE request is acknowledged unconditionally and immediately. 1h = IDLE request is never acknowledged. 2h = IDLE request acknowledgement is based on the internal module activity. 3h = Reserved. Do not use.
2	ENWAKEUP	R	0h	Asynchronous wakeup gereration. 0h = Wakeup generation is disabled. 1h = Enable wakeup generation.
1	SOFTRESET	W	0h	Module software reset. 0h = No Description 1h = Start a soft reset sequence of the Spin Lock module.
0	AUTOGATING	R	1h	Internal OCP clock gating strategy. 0h = OCP clock is not gated when OCP interface is idle. 1h = Automatic internal OCP clock gating strategy is applied, based on the OCP interface activity.

18.2.1.3 SPINLOCK_SYSTS Register (offset = 14h) [reset = 1000001h]

Register mask: FFFFFFFFh

SPINLOCK_SYSTS is shown in Figure 18-47 and described in Table 18-60.

This register provides status information about this instance of the Spin Lock module.

18.2.1.4 SPINLOCK_REG_0 Register (offset = 800h) [reset = 0h]

Register mask: FFFFFFFFh

SPINLOCK_REG_0 is shown in Figure 18-48 and described in Table 18-61.

This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.

18.2.1.11 SPINLOCK_REG_7 Register (offset = 81Ch) [reset = 0h]

Register mask: FFFFFFFFh

SPINLOCK_REG_7 is shown in Figure 18-55 and described in Table 18-68.

This register is read when attempting to acquire a lock. The lock is automatically taken if it was not taken and the value returned by the read is zero. If the lock was already taken, then the read returns one. Writing a zero to this register frees the lock.

Timers

This chapter describes the timers for the device.

Topic **Page**

19.1 DMTimer

19.1.1 Introduction

The timer module contains a free running upward counter with auto reload capability on overflow. The timer counter can be read and written in real-time (while counting). The timer module includes compare logic to allow an interrupt event on a programmable counter matching value.

A dedicated output signal can be pulsed or toggled on overflow and match event. This output offers a timing stamp trigger signal or PWM (pulse-width modulation) signal sources. A dedicated output signal can be used for general purpose PORGPOCFG (directly driven by bit 14 of the TCLR register). A dedicated input signal is used to trigger automatic timer counter capture and interrupt event, on programmable input signal transition type. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged in one module interrupt line and one wake-up line. Each internal interrupt source can be independently enabled/disabled.

This module is controllable through the OCP peripheral bus.

As two clock domains are managed inside this module, resynchronization is done by special logic between the OCP clock domain and the Timer clock domain. At reset, synchronization logic allows utilization of all ratios between the OCP clock and the Timer clock. A drawback of this mode is that full-resynchronization path is used with access latency performance impact in terms of OCP clock cycles. In order to improve module access latency, and under restricted conditions on clocks ratios, write-posted mode can be used by setting the POSTED bit of the System Control Register (TSCR). Under this mode, write posted mode is enabled, meaning that OCP write command is granted before the write process completes in the timer clock domain. This mode allows software to do concurrent writes on Dual Mode timer registers and to observe write process completion (synchronization) at the software level by reading independent write posted status bits in the Write Posted Status Register (TWPS).

19.1.1.1 Features

The timer consists of the following features:

- Counter timer with compare and capture modes
- Auto-reload mode
- Start-stop mode
- Programmable divider clock source
- 16-32 bit addressing
- “On the fly” read/write registers
- Interrupts generated on overflow, compare and capture
- Interrupt enable
- Wake-up enable (only for Timer0)
- Write posted mode
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated output signal for general purpose use PORGPOCFG
- OCP interface compatible

The Timer resolution and interrupt period are dependent on the selected input clock and clock prescaler value. Example resolutions for common clock values are shown in Table 19-1.

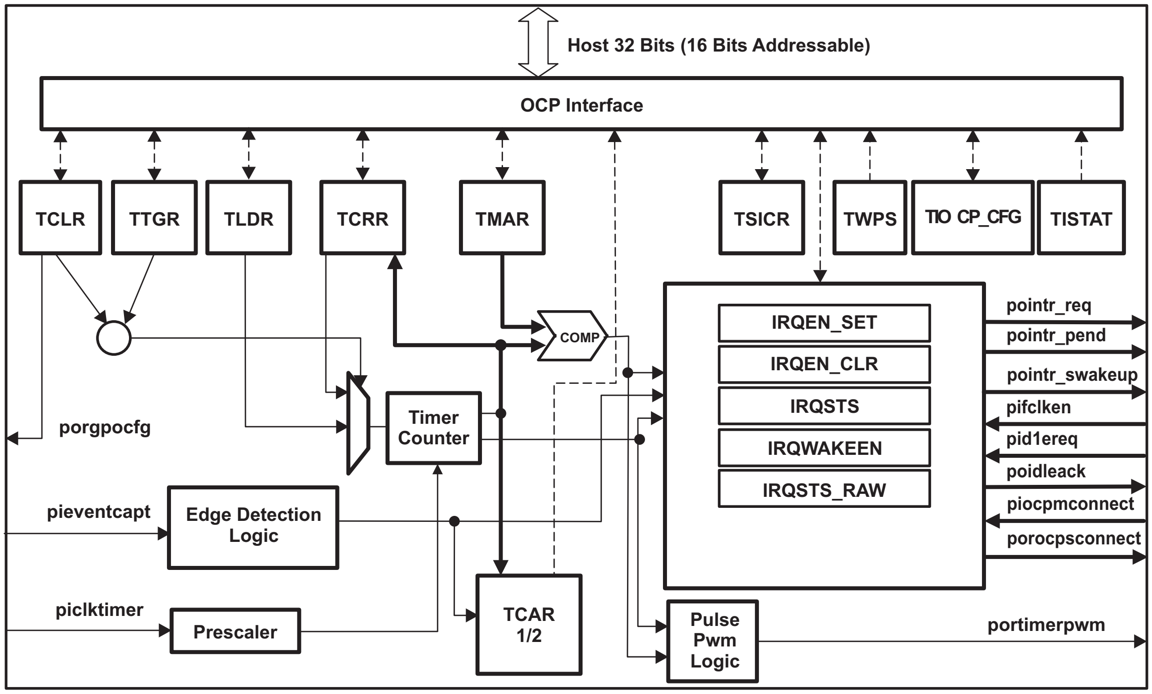
Table 19-1. Timer Resolution and Maximum Range

Clock	Prescaler	Resolution	Interrupt Period Range
32.768 KHz	1 (min)	31.25 us	31.25 us to ~36h 35m
	256 (max)	8 ms	8 ms to ~391d 22h 48m
25 MHz	1 (min)	40 ns	40 ns to ~171.8s
	256 (max)	10.24 us	~20.5 us to ~24h 32m

19.1.1.2 Functional Block Diagram

Figure 19-1 shows a block diagram of the timer.

Figure 19-1. Timer Block Diagram



19.1.2 Integration

The integration for each timer is shown in the following figures:

- Timer0: Figure 19-2
- Timer2–7: Figure 19-3
- Timer8–11: Figure 19-4

Figure 19-2. Timer0 Integration

19.1.2.1 Timer Connectivity Attributes

Table 19-2. Timer[0] Connectivity Attributes

Attributes	Type
Power domain	Wakeup domain
Clock Domain	PD_WKUP_L4_WKUP_GCLK (Interface/OCP) PD_WKUP_TIMER0_GCLK (Func)
Reset Signals	WKUP_DOM_RST_N
Idle/Wakeup Signals	Smart Idle Slave Wakeup
Interrupt Requests	1 to MPU Subsystem (TINT0), Wakeup Processor, EDMA SWAKEUP to Wakeup Processor
DMA Requests	None
Physical Address	L4 Wakeup slave port

Table 19-3. Timer[2–11] Connectivity Attributes

Attributes	Type
Power Domain	Peripheral Domain
Clock Domain	PD_PER_L4LS_GCLK (OCP) Functional Clocks: PD_PER_TIMER2_GCLK (Timer 2) PD_PER_TIMER3_GCLK (Timer 3) PD_PER_TIMER4_GCLK (Timer 4) PD_PER_TIMER5_GCLK (Timer 5) PD_PER_TIMER6_GCLK (Timer 6) PD_PER_TIMER7_GCLK (Timer 7) PD_PER_TIMER8_GCLK (Timer 8) PD_PER_TIMER9_GCLK (Timer 9) PD_PER_TIMER10_GCLK (Timer 10) PD_PER_TIMER11_GCLK (Timer 11)
Reset Signals	PER_DOM_RST_N
Idle/Wakeup Signals	Smart Idle (No wakeup capabilities)
Interrupt Requests	1 per timer module to MPU Subsystem (TINT2 - TINT7) Also to EDMA for Timer 2–Timer 7 Also to TSC_ADC event capture mux for Timer 4–Timer7
DMA Requests	Interrupt requests are redirected as DMA requests: 1 per instance (TINTx)
Physical Address	L4 Peripheral slave port

19.1.2.2 Timer Clock and Reset Management

The DMTimer0 functional clock is sourced from the on-chip ~32.768 kHz oscillator (CLK_RC32K).

Each DMTimer[2–7] functional clock is selected within the PRCM using the associated CLKSEL_TIMERx_CLK register from the following possible sources:

- The 24-MHz (typ) system clock (CLK_M_OSC)
- The PER PLL generated 32.768 KHz clock (CLK_32KHZ)
- The TCLKIN external timer input clock.

Each DMTimer[8-11] functional clock is selected within the PRCM using the associated CLKSEL_TIMERx_CLK register from the following possible sources:

- The 24-MHz (typ) system clock (CLK_M_OSC)
- The PER PLL generated 32.768 KHz clock (CLK_32KHZ)
- The TCLKIN external timer input clock

19.1.2.3 Timer Clock Signals

Table 19-4. Timer[0, 2-7] Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
		Timer[0] Clock Signals	
PICLKOCP Interface clock	26 MHz	CLK_M_OSC	pd_wkup_l4_wkup_gclk from PRCM
PICLKTIMER Functional clock	26 MHz	CLK_RC32K	pd_wkup_timer0_gclk from PRCM
		Timer[2–7] Clock Signals	
PICLKOCP Interface clock	100 MHz	CORE_CLKOUTM4 / 2	pd_per_l4ls_gclk from PRCM
PICLKTIMER Functional clock	26 MHz	CLK_M_OSC CLK_32KHZ (PER_CLKOUTM2 / 5859.375) TCLKIN	pd_per_timer2_gclk pd_per_timer3_gclk pd_per_timer4_gclk pd_per_timer5_gclk pd_per_timer6_gclk pd_per_timer7_gclk from PRCM

Clock Signal	Max Freq	Reference / Source	Comments
PICLKOCP Interface clock	100 MHz	CORE_CLKOUTM4/2	pd_perl4ls_gclk from PRCM
PICLKTIMER Functional clock	26 MHz	CLK_M_OSC CLK_32KHZ (PER_CLKOUTM2 / 5859.375) TCLKIN	pd_per_timer8_gclk pd_per_timer9_gclk pd_per_timer10_gclk pd_per_timer11_gclk

19.1.2.4 Timer Pin List

The timer PIEVENTCAPT input and PORTIMERPWM output signals are muxed onto a single TIMER I/O pad. The pad direction (and hence the pin function) are controlled from within the DMTimer module using the PORGPOCFG signal as an output enable.

Table 19-6. Timer Pin List

Pin	Type	Description
TCLKIN	I	External timer clock source
TIMER0	I/O	Timer 0 trigger input or PWM output
TIMER4	I/O	Timer 4 trigger input or PWM output
TIMER5	I/O	Timer 5 trigger input or PWM output
TIMER6	I/O	Timer 6 trigger input or PWM output
TIMER7	I/O	Timer 7 trigger input or PWM output

19.1.3 Functional Description

The general-purpose timer is an upward counter. It supports 3 functional modes:

- Timer mode
- Capture mode
- Compare mode

By default, after core reset, the capture and compare modes are disabled.

19.1.3.1 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the Timer Control Register (TCLR ST bit). The Timer Counter Register (TCRR) can be loaded when stopped or on the fly (while counting). TCRR can be loaded directly by a TCRR Write access with the new timer value. TCRR can also be loaded with the value held in the Timer Load Register (TLDR) by a trigger register (TTGR) Write access. The TCRR loading is done regardless of the value written to TTGR. The value of the timer counter register (TCRR) can be read when stopped or captured on the fly by a TCRR Read access. The timer is stopped and the counter value is cleared to “0” when the module’s reset is asserted. The timer is maintained in stop after reset is released. When the timer is stopped, TCRR is frozen. The timer can be restarted from the frozen value unless TCRR has been reloaded with a new value.

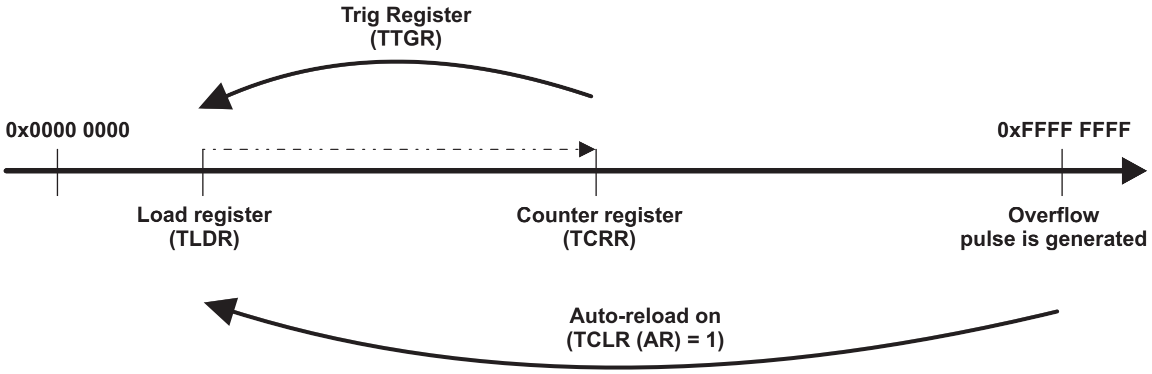
In the one shot mode (TCLR AR bit = 0), the counter is stopped after counting overflow (counter value remains at zero).

When the auto-reload mode is enabled (TCLR AR bit = 1), the TCRR is reloaded with the Timer Load Register (TLDR) value after a counting overflow.

It is not recommended to put the overflow value (FFFF FFFFh) in TLDR because it can lead to undesired results.

An interrupt can be issued on overflow if the overflow interrupt enable bit is set in the timer Interrupt Enable Register (IRQEN_SET OVF_IT_FLAG bit = 1). A dedicated output pin (PORTIMERPWM) is programmed through TCLR (TRG and PT bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs.

Figure 19-5. TCRR Timing Value



19.1.3.2 Capture Mode Functionality

The timer value in TCRR can be captured and saved in TCAR1 or TCAR2 function of the mode selected in TCLR through the field CAPT_MODE when a transition is detected on the module input pin (PIEVENTCAPT). The edge detection circuitry monitors transitions on the input pin (PIEVENTCAPT).

Rising transition, falling transition or both can be selected in TCLR (TCM bit) to trigger the timer counter capture. The module sets the IRQSTS (TCAR_IT_FLAG bit) when an active transition is detected and at the same time the counter value TCRR is stored in one of the timer capture registers TCAR1 or TCAR2 as follows:

- If TCLR's CAPT_MODE field is 0 then, on the first enabled capture event, the value of the counter register is saved in TCAR1 register and all the next events are ignored (no update on TCAR1 and no interrupt triggering) until the detection logic is reset or the interrupt status register is cleared on TCAR's position writing a 1 in it.
- If TCLR's CAPT_MODE field is 1 then, on the first enabled captured event, the counter value is saved in TCAR1 register and, on the second enabled capture event, the value of the counter register is saved in TCAR2 register. All the other events are ignored (no update on TCAR1/2 and no interrupt triggering) until the detection logic is reset or the interrupt status register is cleared on TCAR's position writing a 1 in it. This mechanism is useful for period calculation of a clock if that clock is connected to the PIEVENTCAPT input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The TCAR_IT_FLAG bit of IRQSTS (previously 1) is cleared. The timer functional clock (input to prescaler) is used to sample the input pin (PIEVENTCAPT). Negative or positive pulses can be detected when the pulse time exceeds the functional clock period. An interrupt can be issued on transition detection if the capture interrupt enable bit is set in the Timer Interrupt Enable Register IRQEN_SET (TCAR_IT_FLAG bit).

In Figure 19-6, the TCM value is 01 and CAPT_MODE is 0 - only rising edge of the PIEVENTCAPT will trigger a capture in TCAR and only TCAR1 will update.

In Figure 19-7, the TCM value is 01 and CAPT_MODE is 1 - only rising edge of the PIEVENTCAPT will trigger a capture in TCAR1 on first enabled event and TCAR2 will update on the second enabled event.

Figure 19-6. Capture Wave Example for CAPT_MODE = 0

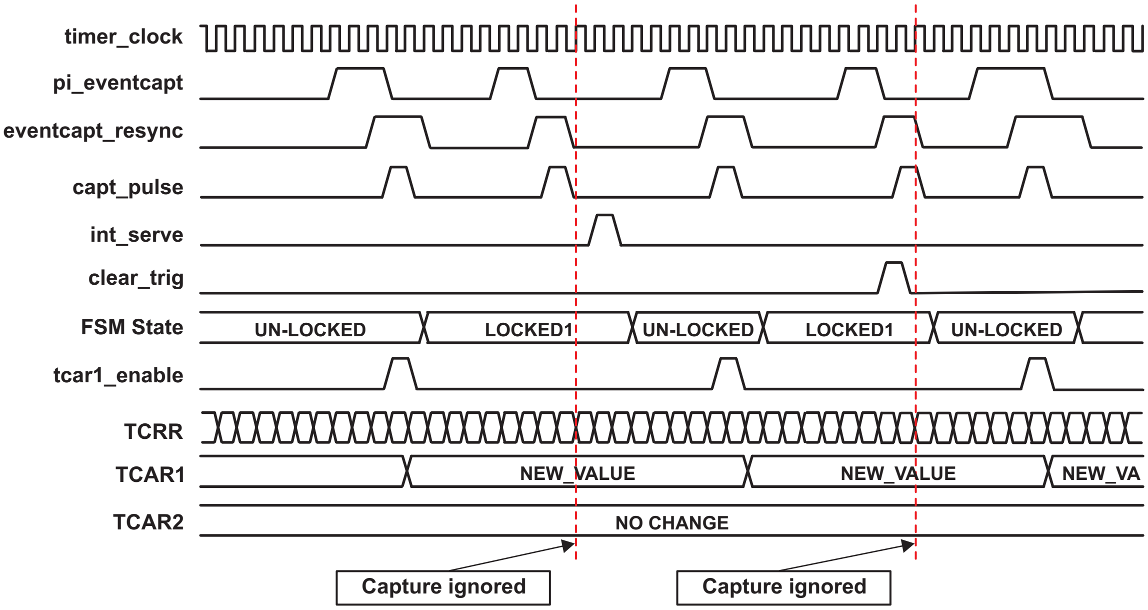


Figure 19-7. Capture Wave Example for CAPT_MODE = 1

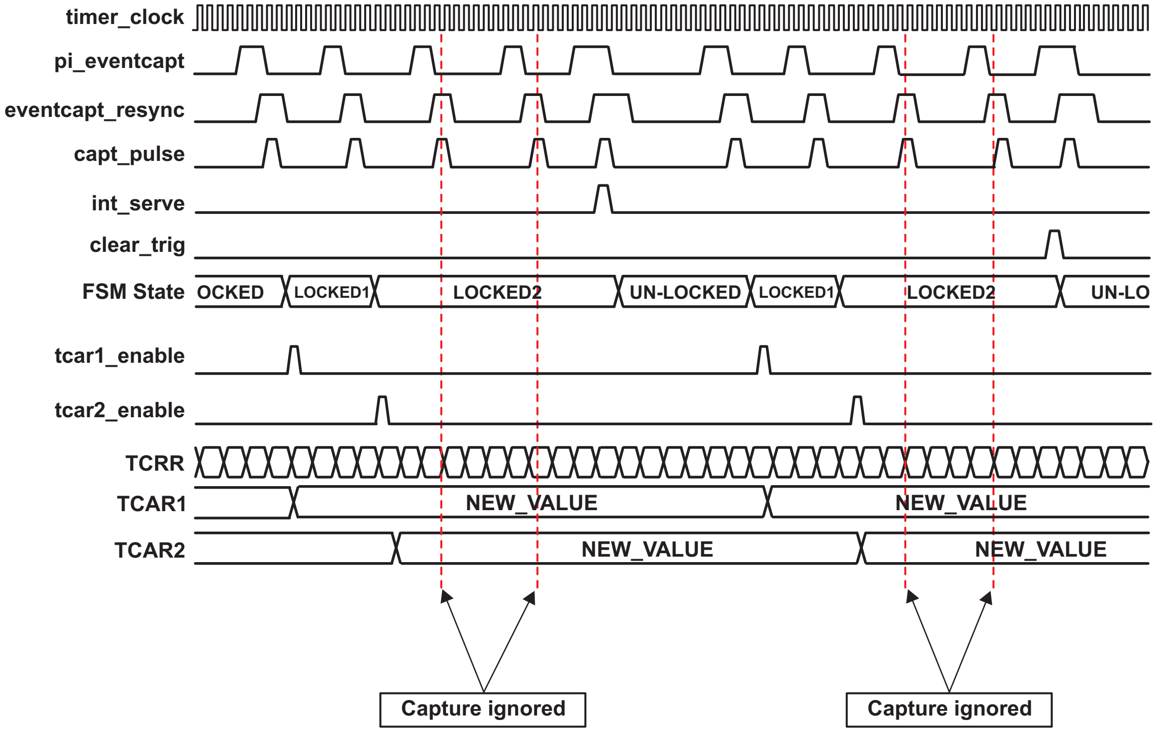

19.1.3.3 Compare Mode Functionality

When Compare Enable TCLR (CE bit) is set to 1, the timer value (TCRR) is permanently compared to the value held in timer match register (TMAR). TMAR value can be loaded at any time (timer counting or stop). When the TCRR and the TMAR values match, an interrupt can be issued if the IRQEN_SET (MAT_EN_FLAG bit) is set. The correct implementation is to write a compare value in TMAR register before setting TCLR (CE bit) to avoid any unwanted interrupts due to a reset value matching effect.

The dedicated output pin (PORTIMERPWM) can be programmed through TCLR (TRG and PT bits) to generate one positive pulse (TIMER clock duration) or to invert the current value (toggle mode) when an overflow and a match occur.

19.1.3.4 Prescaler Functionality

A prescaler counter can be used to divide the timer counter input clock frequency. The prescaler is enabled when TCLR bit 5 is set (PRE). The 2n division ratio value (PTV) can be configured in the TCLR register. The prescaler counter is reset when the timer counter is stopped or reloaded on the fly.

Table 19-7. Prescaler Functionality

Contexts	Prescaler Counter	Timer Counter
Overflow (when Auto-reload on)	Reset	TLDR
TCRR Write	Reset	TCRR
TTGR Write	Reset	TLDR
Stop	Reset	Frozen

19.1.3.5 Pulse-Width Modulation

The timer can be configured to provide a programmable pulse-width modulation (PORTIMERPWM) output. The PORTIMERPWM output pin can be configured to toggle on a specified event. TCLR (TRG bits) determines on which register value the PORTIMERPWM pin toggles. Either overflow or match can be used to toggle the PORTIMERPWM pin, when a compare condition occurs.

In case of overflow and match mode, the match event will be ignored from the moment the mode was set-up until the first overflow event occurs (see Figure 19-7).

The TCLR (SCPWM bit) can be programmed to set or clear the PORTIMERPWM output signal while the counter is stopped or the triggering is off only. This allows fixing a deterministic state of the output pin when modulation is stopped. The modulation is synchronously stopped when the TRG bit is cleared and an overflow has occurred.

In the following timing diagram, the internal overflow pulse is set each time (FFFF FFFFFh – TLDR + 1) value is reached, and the internal match pulse is set when the counter reaches TMAR register value. According to TCLR (TRG and PT bits) programming value, the timer provides pulse or PWM on the output pin (PORTIMERPWM).

The TLDR and TMAR registers must keep values smaller than the overflow value (FFFF FFFFh) with at least 2 units. In case the PWM trigger events are both overflow and match, the difference between the values kept in TMAR register and the value in TLDR must be at least 2 units. When match event is used, the compare mode TCLR (CE) must be set.

In Figure 19-8, TCLR (SCPWM bit) is cleared to 0. In Figure 19-9, TCLR (SCPWM bit) is set to 1.

Figure 19-8. Timing Diagram of Pulse-Width Modulation with SCPWM = 0

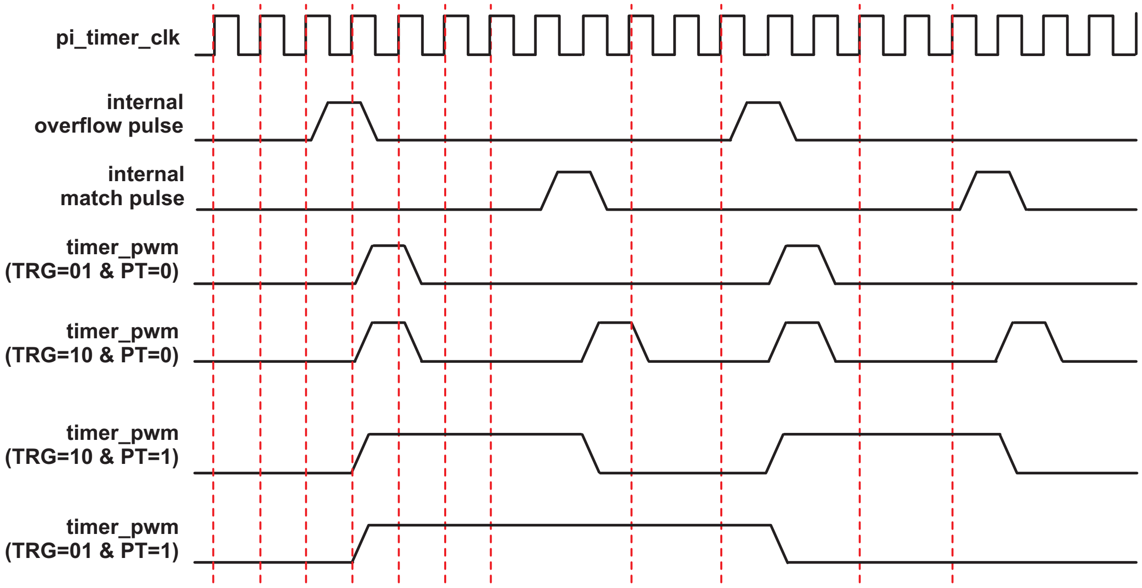

Figure 19-9. Timing Diagram of Pulse-Width Modulation with SCPWM = 1

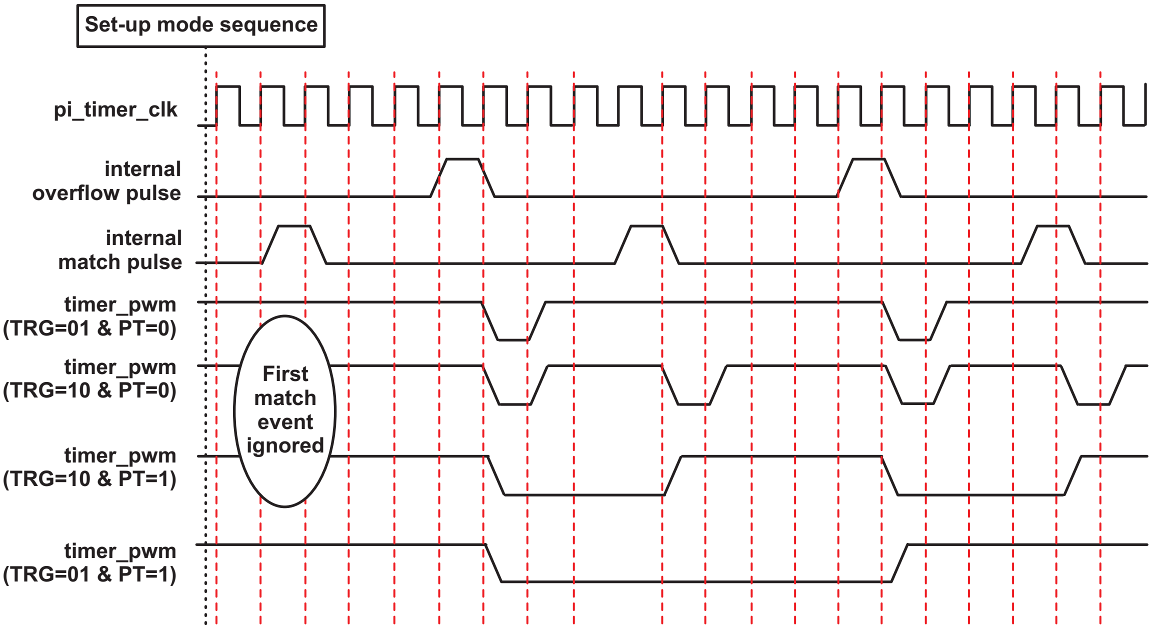


19.1.3.6 Timer Counting Rate

The timer counter is composed of a prescaler stage and a timer counter. Prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio can be managed by accessing the ratio definition field of the control register (PTV and PRE of TCLR). See Table 19-8.

The timer rate is defined by:

- The value of the prescaler fields (PRE and PTV of TCLR register)
- The value loaded into the Timer Load Register (TLDR).

Table 19-8. Prescaler Clock Ratios Value

PRE	PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32
1	5	64
1	6	128
1	7	256

The timer rate equation is as follows:

(FFFF FFFFh – TLDR + 1) × timer Clock period × Clock Divider (PS)

With timer Clock period = 1/ timer Clock frequency and PS = 2(PTV + 1).

As an example, if we consider a timer clock input of 32 kHz, with a PRE field equal to 0, the timer output period is:

Table 19-9. Value and Corresponding Interrupt Period

TLDR	Interrupt period
0000 0000h	37 h
FFFF 0000h	2 s
FFFF FFF0h	500 us
FFFF FFFEh	62.5 us

19.1.3.7 Dual Mode Timer Under Emulation

To configure the Timer to stop during emulation suspend events (for example, debugger breakpoints), set up the Timer and the Debug Subsystem:

1. Set TIOCP_CFG.EMUFREE=0. This will allow the Suspend_Control signal from the Debug Subsystem (Chapter 31) to stop and start the Timer. Note that if EMUFREE=1, the Suspend_Control signal is ignored and the Timer is free running regardless of any debug suspend event. This EMUFREE bit gives local control from a module perspective to gate the suspend signal coming from the Debug Subsystem.
2. Set the appropriate xxx_Suspend_Control register = 0x9, as described in Section 31.1.1.1, *Debug Suspend Support for Peripherals*. Choose the register appropriate to the peripheral you want to suspend during a suspend event.

19.1.3.8 Accessing Registers

All registers are 32-bit wide, accessible via OCP interface with 16-bit or 32-bit OCP access (Read/Write). The 32-bit registers write update in 16 bits access must be LSB16 first and the second write access must be MSB16. For the write operation, the module allows skipping the MSB access if the user does not need to update the 16 MSB bits of the register, but only for the OCP registers (TIDR, TIOCP_CFG, IRQSTS_RAW, IRQSTS, IRQEN_SET, IRQEN_CLR, IRQWAKEEN and TSICR). The write operation on any functional register (TCLR, TCRR, TLDR, TTGR and TMAR) must be complete (the MSB must be written even if the MSB data is not used).

19.1.3.8.1 Programming the Timer Registers

The TLDR, TCRR, TCLR, TIOCP_CFG, IRQSTS, IRQEN_SET, IRQEN_CLR, IRQWAKEEN, TTGR, TSICR and TMAR registers write is done synchronously with OCP clock, by the host, using the OCP bus protocol.

19.1.3.8.2 Reading the Timer Registers

The counter register (TCRR) is a 32-bit “atomic datum” and 16-bit capture is done on the 16-bit LSB first to allow atomic LSB16 + MSB16 capture. Atomic capture is also performed for the TCAR1 and TCAR2 registers as they may change due to internal processes.

19.1.3.8.3 OCP Error Generation

The timer module responds with error indication in the following cases:

Error on write transactions

- Assert the PORSRESP = ERR signal in the same cycle as PORSCMDACCEPTED.
- Use the ERR code for PORSRESP during the response phase.

Error on read transactions

- Assert the PORSRESP = ERR signal in the same cycle as PORSCMDACCEPTED.
- Use the ERR code for PORSRESP during the response phase. PORSDATA in this case is not valid.

Table 19-10. OCP Error Reporting

Error Type	Response: SRESP = ERR
Unsupported PIOCPMCMD command	Yes
Address error: Read or write to a non-existing internal address	No
Read to write-only registers and write to read-only registers	No
Unaligned address (PIOCPMADDR ≠ 00) on read/write transaction	Yes
Unsupported PIOCPMBYTEEN on read/write transaction	Yes

NOTE: Byte enable “0000” is a supported byte enable.

19.1.3.9 Posted Mode Selection

A choice between the two synchronization modes will be made taking into account the frequency ratio and the stall periods that can be supported by the system, without impacting the global performance.

The posted mode selection applies only to functional registers that require synchronization on/from timer clock domain. For write operation, the registers affected by this posted/non-posted selection are: TCLR, TLDR, TCRR, TTGR and TMAR. For read operation, the register affected by this posted/non-posted selection are: TCRR, TCAR1 and TCAR2.

The OCP clock domain synchronous registers TIDR, TIOCP_CFG, TISTAT, IRQSTS, IRQSTS_RAW, IRQEN_SET, IRQEN_CLR, IRQWAKEEN, TWPS and TSICR are not affected by the posted/non-posted mode selection; the write/read operation is effective and acknowledged (command accepted) after one OCP clock cycle from the command assertion.

19.1.3.10 Write Registers Access

19.1.3.10.1 Write Posted

This mode can be used only if the functional frequency range is freq (timer) < freq (OCP)/4.

This mode is used if TSICR (POSTED bit) is set to 1 in the timer control register.

This mode uses a posted-write scheme to update any internal register. The write transaction is immediately acknowledged on the OCP interface, although the effective write operation will occur later, due to a resynchronisation in the timer clock domain. This has the advantage of not stalling either the interconnect system, or the CPU that requested the write transaction. For each register, a status bit is provided, that is set if there is a pending write access to this register.

In this mode, it is mandatory that the CPU checks the status bit prior to any write access. In case a write is attempted to a register with a previous access pending, the previous access is discarded without notice (this can lead to unexpected results also).

There is one status bit per register, accessible in the Timer Write Posted Status Register. When the timer module operates in this mode, there is an automatic sampling of the current timer counter value, in an OCP-synchronized capture register. Consequently, any read access to the timer counter register does not add any re-synchronization latency; the current value is always available.

A register read following a write posted register (on the same register) is not ensured to read the previous write value if the write posted process is not completed. Software synchronization should be used to avoid a non-coherent read.

The drawback of this automatic update mechanism is that it assumes a given relationship between the OCP interface frequency and the timer functional frequency.

This posted period is defined as the interval between the posted write access request and the reset of the posted bit in TWPS register, and can be quantified:

T (reset posted max.) = 3 OCP clock + 2.5 TIMER clock

The time when the write accomplishes is:

T (write accomplish) = 1 OCP clock + 2.5 TIMER clock

19.1.3.10.2 Write Non-Posted

This mode is functional regardless of the ratio between the OCP interface frequency and the functional clock frequency. The recommended functional frequency range is freq (timer) >= freq (OCP)/4.

This mode is used if TSICR (POSTED bit) is cleared to 0 in the timer control register.

This mode uses a non posted-write scheme to update any internal register. That means the write transaction will not be acknowledged on the OCP interface, until the effective write operation occurs, after the resynchronisation in the timer clock domain. The drawback is that both the interconnect system and the CPU are stalled during this period.

- The latency of the interrupt serving is increased, as the interconnect system and CPU are stalled.
- An interconnect logic, including time-out logic to detect erroneous transactions, can generate an unwanted system abort event.

The stall period is defined as the interval between the non-posted write access request and the rise of the command accept signal and can be quantified:

T (stall max.) = 3 OCP clock + 2.5 TIMER clock

The time when the write accomplishes is:

T (write accomplish) = 1 OCP clock + 2.5 TIMER clock

A register read following a write to the same register is always coherent.

19.1.3.11 Read Registers Access

19.1.3.11.1 Read Posted

This mode can be used only if the functional frequency range is freq (timer) < freq (OCP)/4.

This mode is used if TSICR (POSTED bit) is set to 1 in the timer control register.

This mode uses a posted-read scheme, for reading any internal register. The read transaction is immediately acknowledged on the OCP interface, and the value to be read has been previously resynchronised. This has the advantage of not stalling either the interconnect system, or the CPU that requested the read transaction.

19.1.3.11.2 Read Non-Posted

This mode is functional whatever the ratio between the OCP interface frequency and the functional clock frequency. Recommended functional frequency range is freq (timer) >= freq (OCP)/4.

This mode is used if TSICR (POSTED bit) is cleared to 0 in the timer control register.

This mode uses a non posted-read scheme, for reading any internal register. The read transaction will not be acknowledged on the OCP interface, until the effective read operation occurs, after the resynchronisation in the timer clock domain. The drawback is that both the interconnect system and the CPU are stalled during this period.

- The latency of the interrupt serving is increased, as the interconnect system and the CPU are stalled.
- An interconnect system including time-out logic to detect erroneous transactions can generate an unwanted system abort event.

This mode applies only to three registers: TCRR, TCAR1 and TCAR2, which need resynchronisation from functional to OCP clock domains.

The stall period is defined as the interval between the non-posted read access request and the rise of the command accept signal and can be quantified:

T (stall max.) = 3 OCP clock + 2.5 TIMER clock

The time when the value is sampled is:

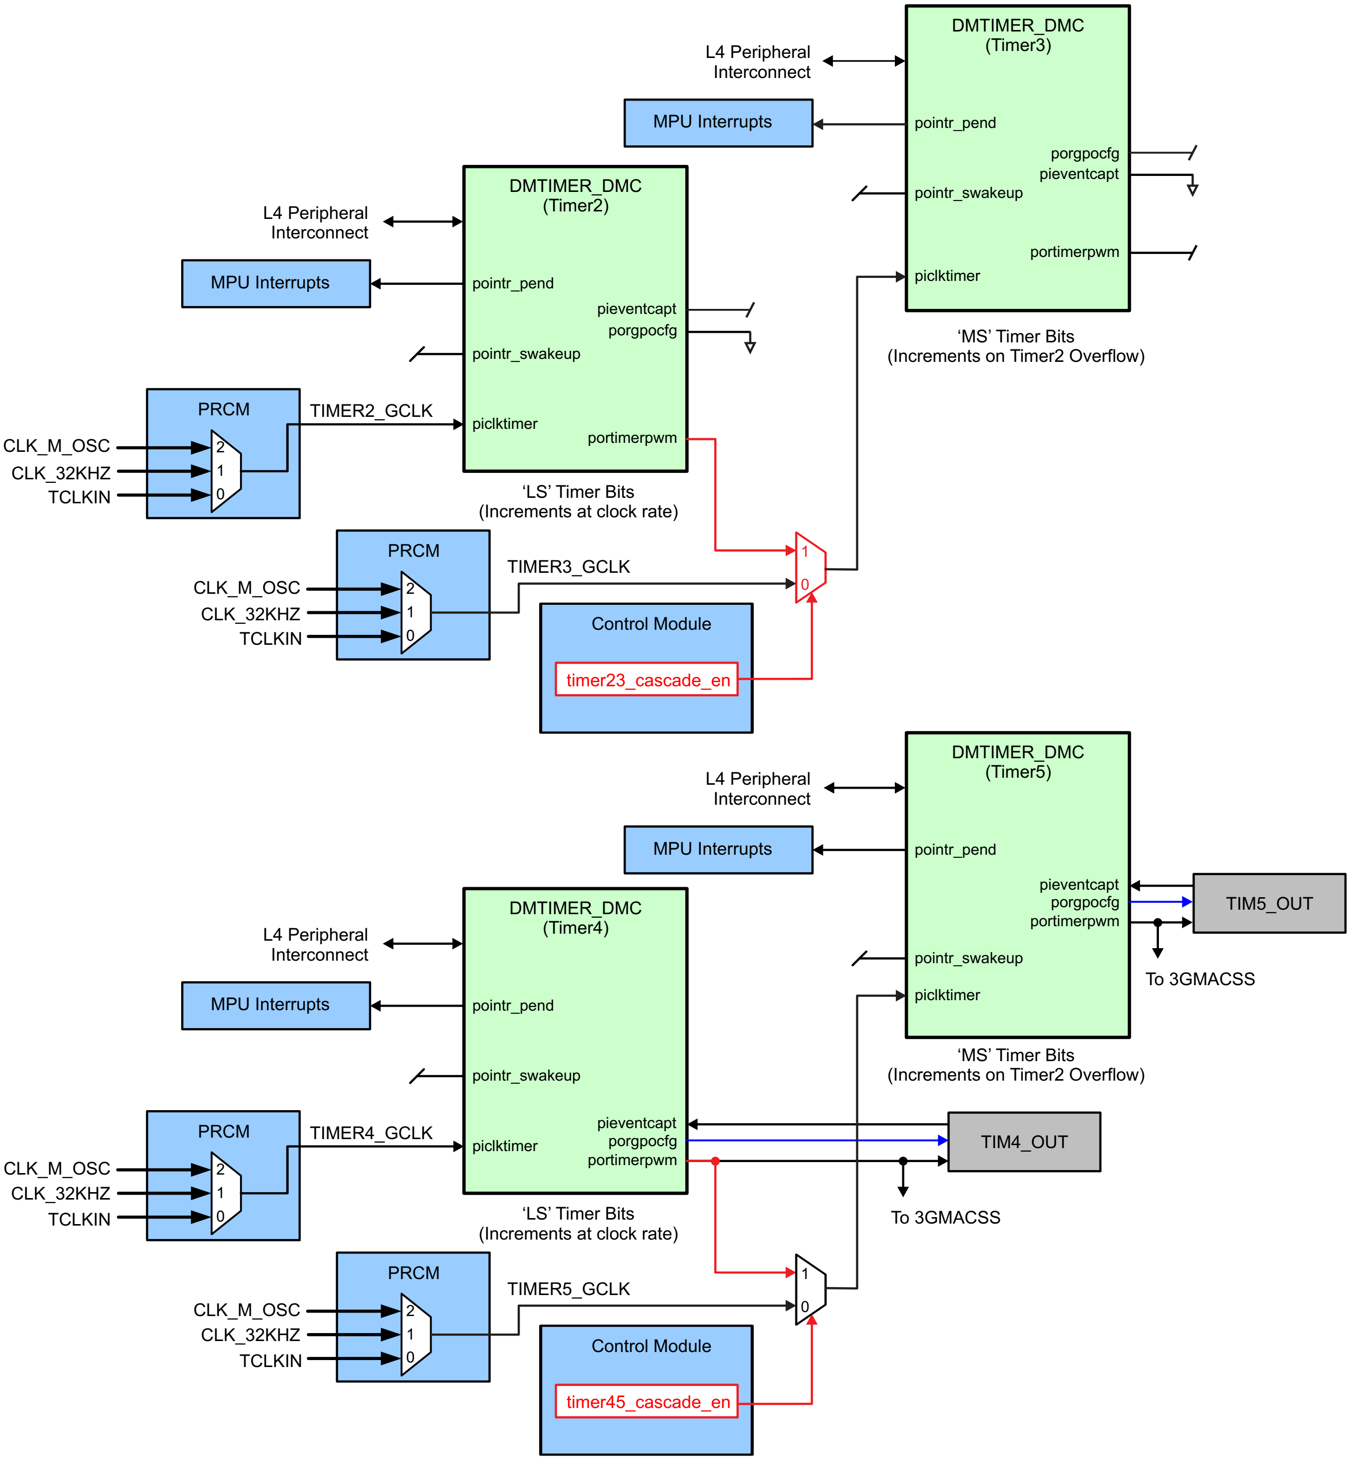
T (read sample) = 1 OCP clock + 2.5 TIMER clock

19.1.3.12 Timer Cascading

In order to provide a 64-bit timer option, the device includes logic to cascade two pairs of Timer modules: DMTIMER2-3 provide a 64-bit internal timer and DMTIMER4-5 provide a 64-bit timer with output capability. The cascade logic consists of an additional mux on the clock input of the second timer in each pair to allow it to be clocked with the output of the first timer in each pair. Cascade mode is selected through the TIMER_CASCADE_CTRL register in the Control Module.

For cascading to work, the LS module must be set to generate only one pulse on the output (PT=0) on overflow (TRG = 01). In this way, the MS Timer counter is incremented each time the LS Timer overflows. (Another configuration option is: PT=1 and TRG = 10).

Figure 19-10. Timer Cascading Details

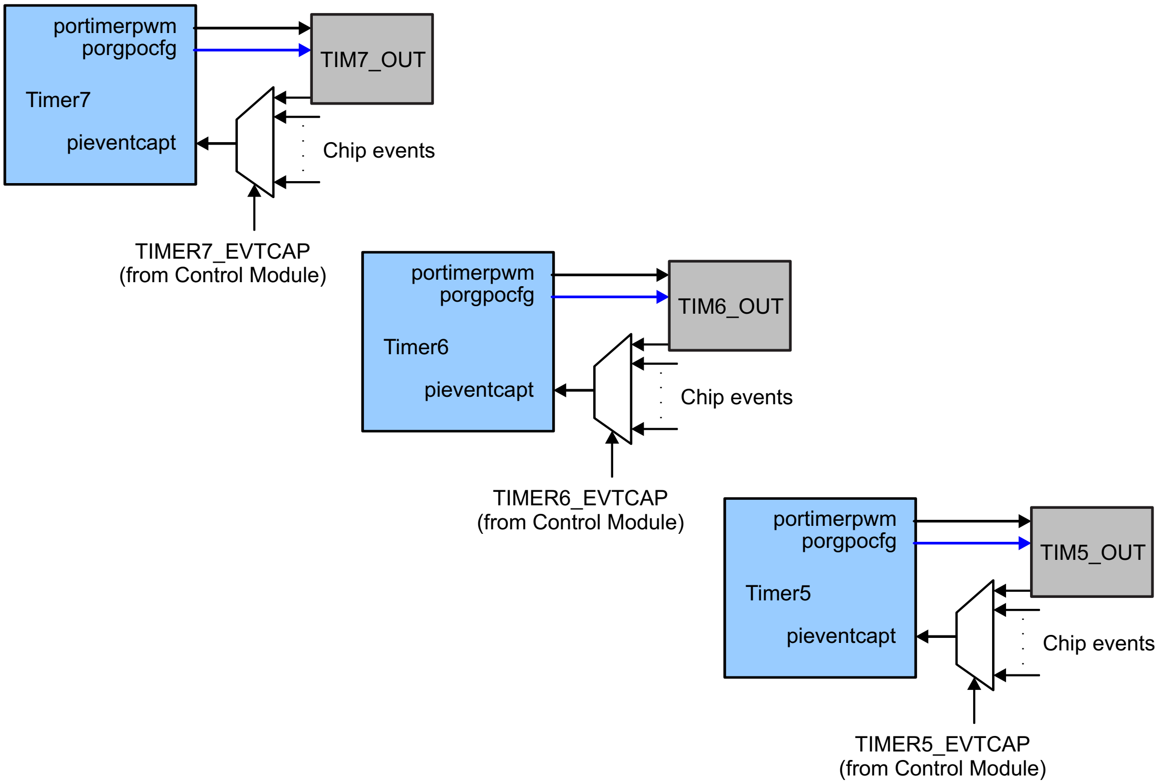


NOTE: Red lines indicate new logic.

19.1.3.13 Timer Synchronization

The timers provide synchronization signals to allow them to be synchronized to other modules or events. This feature is enabled only for Timer0-1 and Timer4-7. On Timer0, Timer1, and Timer4, only the external pin may be used for synchronization. On Timer5-7, the capture events may be selected from among 31 different pins or internal interrupt signals. The event is selected using the corresponding TIMERx_EVTCAPT field of the TIMER_EVT_CAP register in the Control Module.

Figure 19-11. Timer Sync Event Detail



19.1.4 DMTIMER Registers

Table 19-11 lists the memory-mapped registers for the DMTIMER. All register offset addresses not listed in Table 19-11 should be considered as reserved locations and the register contents should not be modified.

Table 19-11. DMTIMER Registers

Offset	Acronym	Register Name	Section
0h	DMTIMER_TIDR		Section 19.1.4.1
10h	DMTIMER_TIOCP_CFG		Section 19.1.4.2

19.1.4.1 DMTIMER_TIDR Register (Offset = 0h) [reset = 4FFF0301h]

Register mask: FFFFFFFFh

DMTIMER_TIDR is shown in Figure 19-12 and described in Table 19-12.

Return to Summary Table.

This read only register contains the revision number of the module. A write to this register has no effect. This Register is used by software to track features, bugs, and compatibility.

Bit	Field	Type	Reset	Description
31-4	RESERVED	R	0h	
3-2	IDLEMODE	R/W	0h	Power management, req/ack control 0h (R/W) = Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, i.e. regardless of the IP module's internal requirements. Backup mode, for debug only. 1h (R/W) = No-idle mode: local target never enters idle state. Backup mode, for debug only. 2h (R/W) = Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wakeup events. 3h (R/W) = Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state. Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented.
1	EMUFREE	R/W	0h	Sensitivity to emulation (debug) suspend event from Debug Subsystem. 0h (R/W) = The timer is frozen during a debug suspend event. 1h (R/W) = The timer runs free. Debug suspend event is ignored.
0	SOFTRESET	R/W	0h	Software reset. 0h (R/W) = Read 0 : reset done, no pending action Write 0 : no action 1h (R/W) = Read 1 : initiate software reset Write 1 : Reset ongoing

19.1.4.3 DMTIMER_IRQ_EOI Register (Offset = 20h) [reset = 0h]

Register mask: FFFFFFFFh

DMTIMER_IRQ_EOI is shown in Figure 19-14 and described in Table 19-14.

Return to Summary Table.

Software End-Of-Interrupt: Allows the generation of further pulses on the interrupt line, if an new interrupt event is pending, when using the pulsed output. Unused when using the level interrupt line (depending on module integration).

19.2 DMTimer 1ms

19.2.1 Introduction

This peripheral is a 32-bit timer offering:

- Counter timer with compare and capture modes
- Auto-reload mode
- Start-stop mode
- Generate 1 ms tick with 32768-Hz functional clock
- Programmable divider clock source
- 16–32 bit addressing
- On-the-fly read/write registers
- Interrupts generated on overflow, compare and capture
- Interrupt enable
- Wake-up enable
- Write posted mode
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated output signal for general purpose use PORGPOCFG
- OCP interface compatible

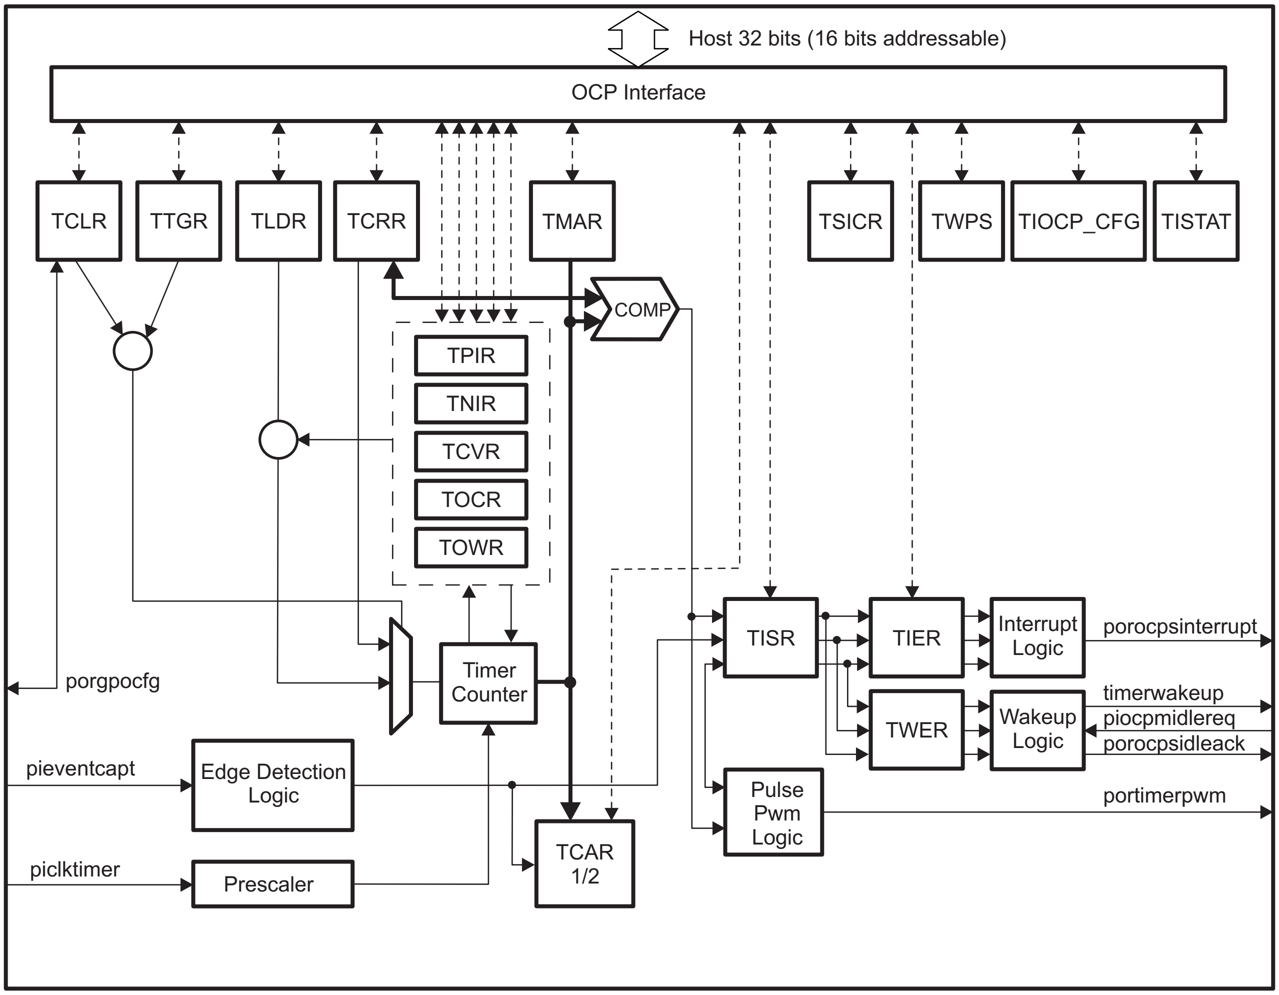
The timer module contains a free running upward counter with auto reload capability on overflow. The timer counter can be read and written on the fly (while counting). The timer module includes compare logic to allow interrupt event on programmable counter matching value.

A dedicated output signal can be pulsed or toggled on overflow and match event. This output offers timing stamp trigger signal or PWM (pulse width modulation) signal sources. A dedicated output signal can be used for general purpose PORGPOCFG (directly driven by the bit 14 of the TCLR register). A dedicated input signal is used to trigger automatic timer counter capture and interrupt event, on programmable input signal transition type. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged in one module interrupt line and one wake-up line. Each internal interrupt source can be independently enabled/disabled with a dedicated bit of TIER register for the interrupt features and a dedicated bit of TWER for the wake-up.

This module is controllable through the OCP peripheral bus.

As two clocks domains are managed inside this module, resynchronization is done by special logic between OCP clock domain and Timer clock domain. At reset, synchronization logic allows utilization of all ratios between OCP clock and Timer clock. Drawback of this mode is that full-resynchronization path is used with access latency performance impact in terms of OCP clock cycles. In order to improve module access latency, and under restricted conditions on clocks ratios (cf. 7.1 Write posted), write-posted mode can be used by setting POSTED bit of System Control register (TSICR). Under this mode, write posted mode is enabled, meaning that OCP write command is granted before the write process completes in the timer clock domain. This mode allows software (SW) to do concurrent writes on Dual Mode timer registers and to observe write process completion (synchronization) at SW level by reading independent write posted status bits in the Write Posted Status Register (TWPS).

Figure 19-29. Block Diagram



19.2.2 Integration

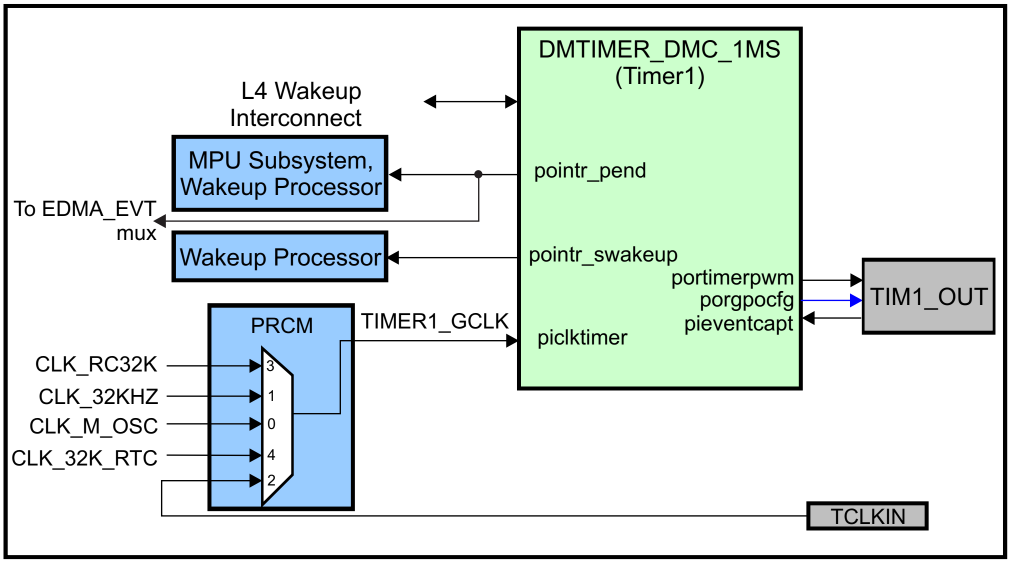


Figure 19-30. DMTimer 1 ms Integration

19.2.2.1 Timer Connectivity Attributes

Table 19-29. Timer1 Connectivity Attributes

Attributes	Type
Power Domain	Wakeup Domain
Clock Domain	PD_WKUP_L4_WKUP_GCLK (OCP) PD_WKUP_TIMER1_GCLK (Func)
Reset Signals	WKUP_DOM_RST_N
Idle/Wakeup Signals	Smart Idle / Slave Wakeup
Interrupt Requests	1 to MPU Subsystem (TINT1_1MS), Wakeup Processor, EDMA SWAKEUP to Wakeup Processor
DMA Requests	None
Physical Address	L4 Wakeup slave port

19.2.2.2 Timer Clock and Reset Manangement

The DMTimer 1ms timer functional clock can be selected from one of the following sources using the CLKSEL_TIMER1MS_CLK register in the PRCM:

- The 24 MHz (typ) system clock (CLK_M_OSC)
- The PER PLL generated 32.768 KHz clock (CLK_32KHZ)
- The TCLKIN external timer input clock
- The on-chip ~32.768 KHz oscillator (CLK_RC32K)
- The external 32.768 KHz crystal/clock (CLK_32K_RTC)

19.2.2.3 Timer Clock Signals

Table 19-30. Timer Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
Timer1 (1ms) Clock Signals			
PICLKOCP Interface clock	26 MHz	CLK_M_OSC	pd_wkup_l4_wkup_gclk from PRCM
PICLKTIMER Functional clock	26 MHz	CLK_M_OSC CLK_32KHZ (PER_CLKOUTM2 / 5859.375) TCLKIN CLK_RC32K CLK_32K_RTC	pd_wkup_timer1_gclk from PRCM

19.2.2.4 Timer Pin List

The timer PIEVENTCAPT input and PORTIMERPWM output signals are muxed onto a single TIMER I/O pad. The pad direction (and hence the pin function) are controlled from within the DMTimer module using the PORGPOCFG signal as an output enable.

Table 19-31. Timer Pin List

Pin	Type	Description
TIMER1	I/O	Timer 1 trigger input or PWM output.

19.2.3 Functional Description

The general-purpose timer is an upward counter. It supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

By default, after core reset, the capture and compare modes are disabled.

19.2.3.1 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the Timer Control Register (TCLR ST bit). The Timer Counter Register (TCRR) can be loaded when stopped or on the fly (while counting). TCRR can be loaded directly by a TCRR Write access with the new timer value. TCRR can also be loaded with the value held in the Timer Load Register (TLDR) by a trigger register (TTGR) Write access. The TCRR loading is done regardless of the value written to the TTGR register. The timer counter register TCRR value can be read when stopped or captured on the fly by a TCRR Read access. The timer is stopped and the counter value set to “0” when the module’s reset is asserted. The timer is maintained in stop after reset is released. When the timer is stopped, TCRR is frozen. The timer can be restarted from the frozen value unless TCRR has been reloaded with a new value.

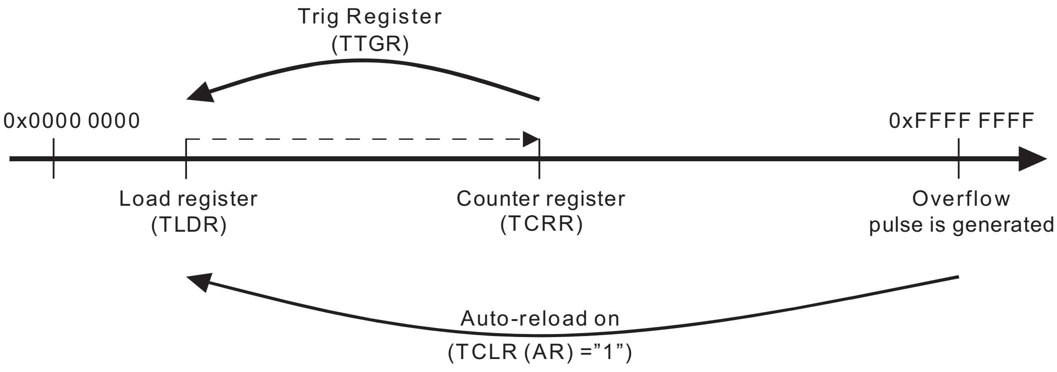
In the one shot mode (TCLR AR bit =”0”), the counter is stopped after counting overflow (counter value remains at zero).

When the auto-reload mode is enabled (TCLR AR bit =”1”), the TCRR is reloaded with the TLDR value after a counting overflow.

It is not recommended to put the overflow value (0xFFFFFFFF) in TLDR because it can lead to undesired results.

An interrupt can be issued on overflow if the overflow interrupt enable bit is set in the timer Interrupt Enable Register (TIER OVF_IT_ENA bit =”1”). A dedicated output pin (PORTIMERPWM) is programmed through TCLR (TRG and PT bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs.

Figure 19-31. TCRR Timing Value



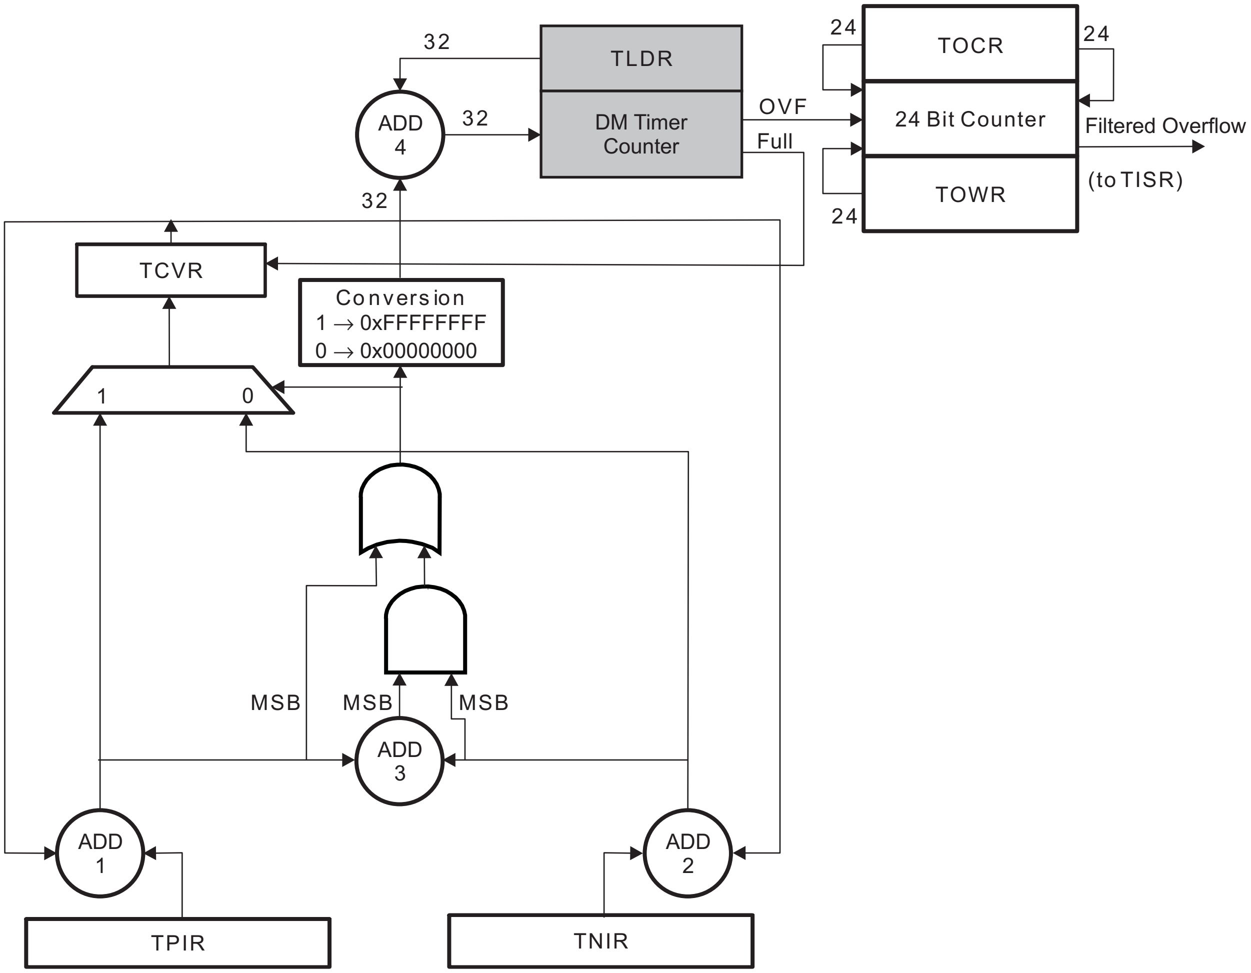
19.2.3.1.1 1 ms Tick Generation

To minimize the error between a true 1ms tick and the tick generated by the 32768 Hz timer, the sequencing of the sub-1ms periods and the over-1ms periods must be shuffled.

An additional block (1ms block) is used to correct this error.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The value of the Timer Positive Increment register (TPIR) and Timer Negative Increment register (TNIR) only need to be defined by the user. An auto adaptation mechanism is used to simplify the programming model.

Figure 19-32. 1ms Module Block Diagram



The TPIR, TNIR, TCVR and adders Add1–3 are used to define whether the next value loaded in the TCRR will be the value of the TLDR (sub-period value) or the value of TLDR – 1 (over-period value).

The following table shows the value loaded in TCRR according to the sign of the result of Add1, Add2 and Add3. MSB = ‘0’ means a positive value, MSB = ‘1’ means a negative value.

Table 19-32. Value Loaded in TCRR to Generate 1ms Tick

Add1 MSB	Add2 MSB	Add3 MSB	TCRR
0	0	0	TLDR
0	0	1	TLDR
0	1	0	TLDR
0	1	1	TLDR - 1
1	0	0	N.A.
1	0	1	N.A.
1	1	0	TLDR - 1
1	1	1	TLDR - 1

The values of TPIR and TNIR registers are calculated with formula:

Positive Increment Value = ((INTEGER[Fclk * Ttick] + 1) * 1e6) - (Fclk * Ttick * 1e6)
Negative Increment Value = (INTEGER[Fclk * Ttick] * 1e6) - (Fclk * Ttick * 1e6)

where:

Fclk – clock frequency (KHz)
Ttick – tick period (ms)

The Timer Overflow Counter Register (TOCR) and the Timer Overflow Wrapping Register (TOWR) are used for interrupt filtering. When the timer overflows, it increments the 24 bit TOCR register. When the 24-bit TOCR register value matches the value in the 24 bit TOWR register and timer overflow is asserted, the TOCR is reset and an interrupt is generated to TISR.

With the Conversion block in reset state (Positive Increment register, Negative Increment register and Counter Value register are all zeroed), the programming model and the behavior of the DMtimer_dmc1ms remain unchanged.

For 1 ms tick with a 32768-Hz clock:

TPIR = 232000
TNIR = -768000
TLDR = 0xFFFFFFE0

NOTE: Any value of the tick period can be generated with the appropriate values of the TPIR, TNIR and TLDR registers.

By default, the TPIR, TNIR, TCVR, TOCR, TOWR registers and the associated logic are in reset mode (all 0s) and have no action on the programming model of the DMtimer_dmc1ms.

19.2.3.2 Capture Mode Functionality

The timer value in TCRR can be captured and saved in TCAR1 or TCAR2 function of the mode selected in TCLR through the field CAPT_MODE when a transition is detected on the module input pin (PIEVENTCAPT). The edge detection circuitry monitors transitions on the input pin (PIEVENTCAPT).

Rising transition, falling transition or both can be selected in TCLR (TCM bit) to trigger the timer counter capture. The module sets the TISR (TCAR_IT_FLAG bit) when an active transition is detected and at the same time the counter value TCRR is stored in one of the timer capture registers TCAR1 or TCAR2 as follows:

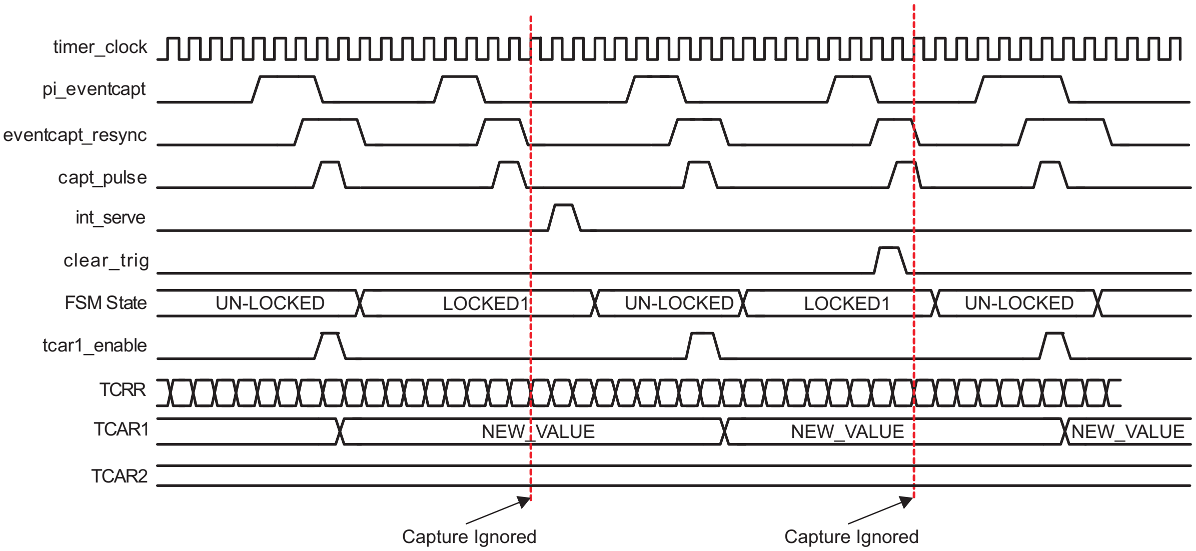
- If TCLR’s CAPT_MODE field is “0” then, on the first enabled capture event, the value of the counter register is saved in TCAR1 register and all the next events are ignored (no update on TCAR1 and no interrupt triggering) until the detection logic is reset or the interrupt status register is cleared on TCAR’s position by writing a “1” to it.
- If TCLR’s CAPT_MODE field is “1” then, on the first enabled captured event, the counter value is saved in TCAR1 register and, on the second enabled capture event, the value of the counter register is saved in TCAR2 register. If capture interrupt is enabled, the interrupt will be asserted on the second event capture. All the other events are ignored (no update on TCAR1/2 and no interrupt triggering) until the detection logic is reset or the interrupt status register is cleared on TCAR’s position writing a “1” in it. This mechanism is useful for period calculation of a clock if that clock is connected to the PIEVENTCAPT input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served. The TCAR_IT_FLAG bit of TISR (previously ‘1’) is cleared by writing a "1" to it or when the edge detection mode bits TCLR (TCM bit) passed from the No Capture Mode detection to any other modes. The timer functional clock (input to prescaler) is used to sample the input pin (PIEVENTCAPT). Negative or positive input pulses can be detected when the pulse time exceeds the functional clock period. An interrupt can be issued on transition detection if the capture interrupt enable bit is set in the Timer Interrupt Enable Register TIER (TCAR_IT_ENA bit).

See the following examples:

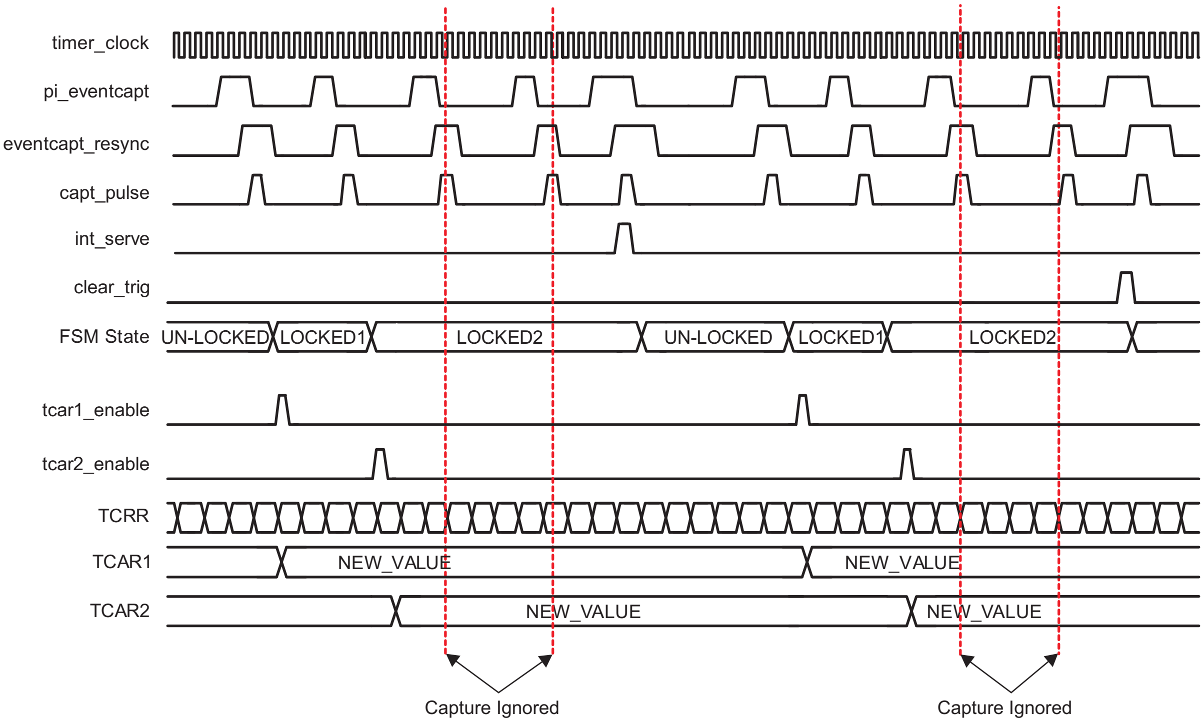
In the next wave, the TCM value is “01” and CAPT_MODE is “0”- only rising edge of the PIEVENTCAPT will trigger a capture in TCAR and only TCAR1 will update.

Figure 19-33. Capture Wave Example for CAPT_MODE 0



In the following example, the TCM value is “01” and CAPT_MODE is “1”- only rising edge of the PIEVENTCAPT will trigger a capture in TCAR1 on first enabled event and TCAR2 will update on the second enabled event.

Figure 19-34. Capture Wave Example for CAPT_MODE 1



19.2.3.3 Compare Mode Functionality

When Compare Enable TCLR (CE bit) is set to “1”, the timer value (TCRR) is permanently compared to the value held in timer match register (TMAR). TMAR value can be loaded at any time (timer counting or stop). When the TCRR and the TMAR values match, an interrupt can be issued if the TIER (MAT_IT_ENA bit) is set. The correct implementation is to write a compare value in TMAR register before setting TCLR (CE bit) to avoid any unwanted interrupts due to a reset value matching effect.

The dedicated output pin (PORTIMERPWM) can be programmed through TCLR (TRG and PT bits) to generate one positive pulse (TIMER clock duration) or to invert the current value (toggle mode) when an overflow and a match occur.

19.2.3.4 Prescaler Functionality

A prescaler counter can be used to divide the timer counter input clock frequency. The prescaler is enabled when TCLR bit 5 is set (PRE). The 2n division ratio value (PTV) can be configured in the TCLR register.

The prescaler counter is reset when the timer counter is stopped or reloaded on the fly.

Table 19-33. Prescaler/Timer Reload Values Versus Contexts

Contexts	Prescaler Counter	Timer Counter
Overflow (when Auto-reload on)	reset	TLDR
TCRR Write	reset	TCRR
TTGR Write	reset	TLDR
Stop	reset	Frozen

19.2.3.5 Pulse-Width Modulation

The timer can be configured to provide a programmable pulse-width modulation (PORTIMERPWM) output. The PORTIMERPWM output pin can be configured to toggle on a specified event. TCLR (TRG bits) determines on which register value the PORTIMERPWM pin toggles. Either overflow or match can be used to toggle the PORTIMERPWM pin, when a compare condition occurs.

In case of overflow and match mode, the match event will be ignored from the moment the mode was set-up until the first overflow event occurs

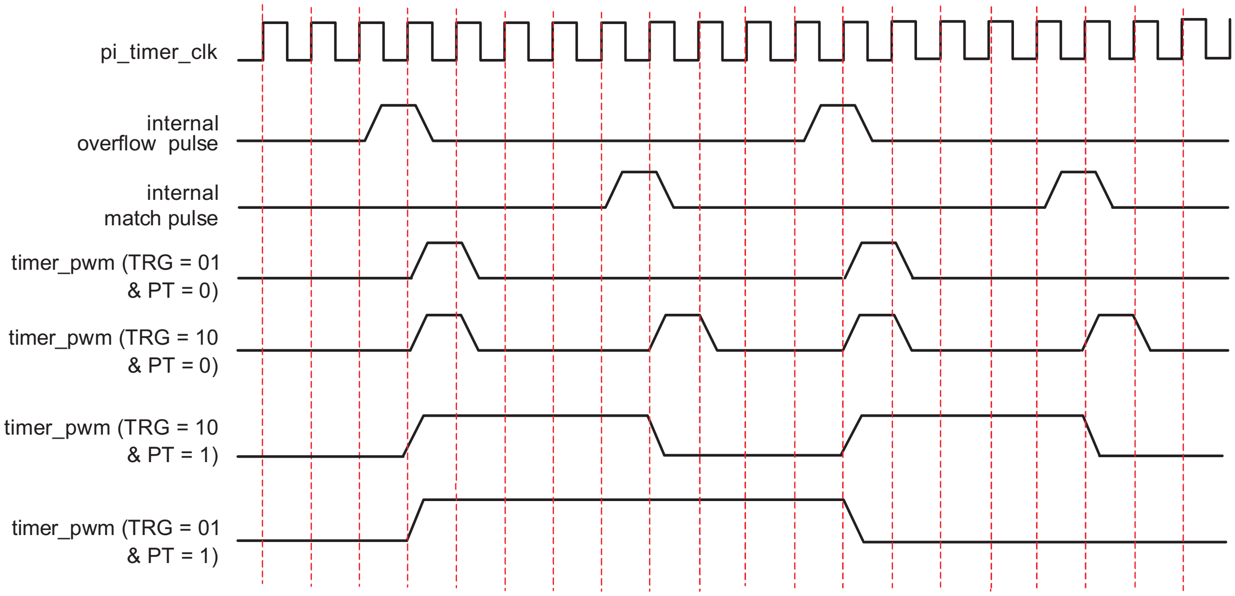
The TCLR (SCPWM bit) can be programmed to set or clear the PORTIMERPWM output signal while the counter is stopped or the triggering is off only. This allows fixing a deterministic state of the output pin when modulation is stopped. The modulation is synchronously stopped when TRG bit is cleared and an overflow has occurred.

In the following timing diagram, the internal overflow pulse is set each time (0xFFFF FFFFF – TLDR +1) value is reached, and the internal match pulse is set when the counter reaches TMAR register value. According to TCLR (TRG and PT bits) programming value, the timer provides pulse or PWM on the output pin (PORTIMERPWM).

The TLDR and TMAR registers must keep values smaller than the overflow value (0xFFFFFFFF) with at least 2 units. In case the PWM trigger events are both overflow and match, the difference between the values kept in TMAR register and the value in TLDR must be at least 2 units. When match event is used, the compare mode TCLR (CE) must be set.

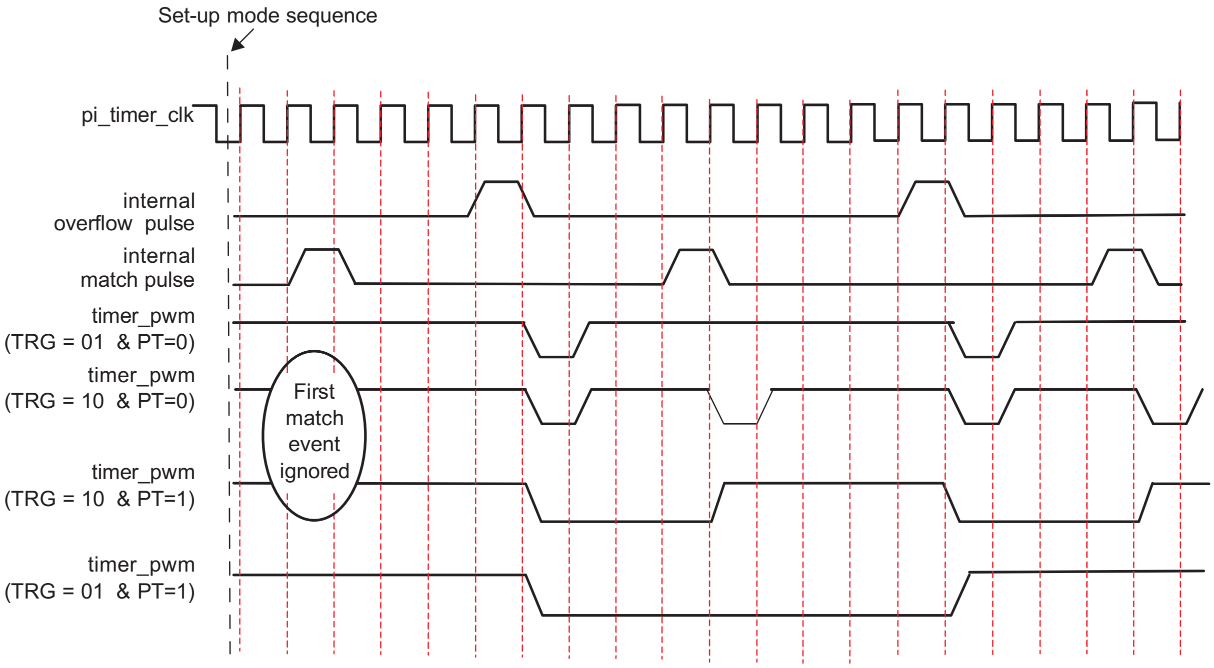
On the following wave TCLR (SCPWM bit) is set to ‘0’.

Figure 19-35. Timing Diagram of Pulse-Width Modulation, SCPWM Bit = 0



On the next wave TCLR (SCPWM bit) is set to ‘1’.

Figure 19-36. Timing Diagram of Pulse-Width Modulation, SCPWM Bit = 1



19.2.3.6 Timer Interrupt Control

The timer can issue an overflow interrupt, a timer match interrupt and a timer capture interrupt. Each internal interrupt source can be independently enabled/disabled in the Interrupt Enable Register (TIER). When the interrupt event has been issued, the associated interrupt status bit is set in the Timer Status Register (TISR). The pending interrupt event is reset when the set status bit is overwritten by a “1” value. Reading the Interrupt Status Register and writing the value back allows for a fast acknowledge interrupt process.

19.2.3.7 Sleep Mode Request and Acknowledge

Upon a Sleep mode request issued by the host processor (the Idle Request PIOCPMIDLEREQ signal is active), the timer module will enter Sleep mode according to the IdleMode field of the System configuration register (see TIOCP_CFG).

If the IdleMode field sets No-Idle mode, the Timer does not enter Sleep mode and the Idle acknowledge signal (POROCPSIDLEACK) is never asserted.

If the IdleMode field sets Force-Idle mode, the timer enters Sleep mode independently of the internal module state and the Idle acknowledge signal (POROCPSIDLEACK) is unconditionally asserted.

If the IdleMode field sets Smart-Idle mode, the timer module evaluates its internal capability to have the interface/functional clock switched off. Depending on the ClockActivity field, setting the timer module evaluates the internal activity and asserts the Idle acknowledge signal (POROCPSIDLEACK), entering in Sleep mode, ready to issue a wake-up request.

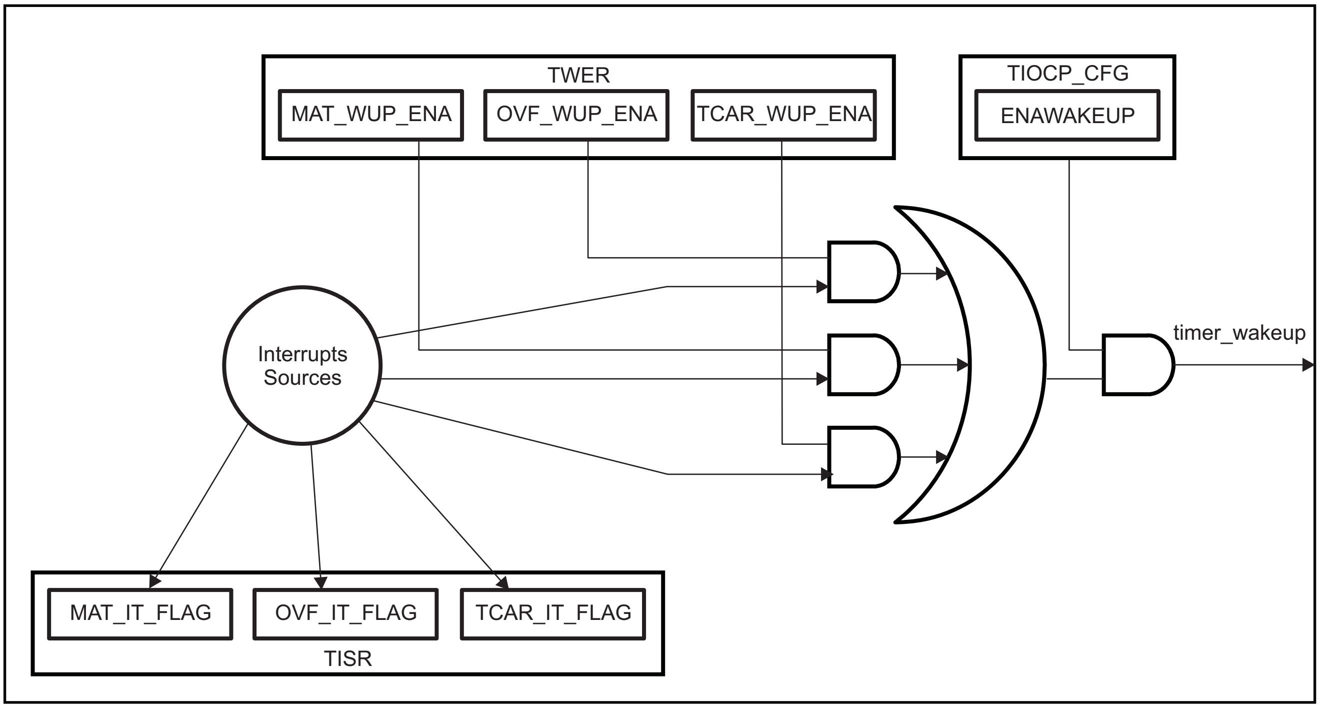
The following table describes the Smart Idle behavior according to the clock activity setting:

Table 19-34. SmartIdle - Clock Activity Field Configuration

Clock Activity	Functional Clock	OCP Clock	Module Behavior
11	ON	ON	The Idle acknowledge signal is asserted when there are no pending activities on the OCP clock domain, without evaluating the pending activities on the functional clock domain. (The module will enter in Sleep mode and if a pending interrupt event is finished during Idle mode the wake-up signal will be asserted).
10	ON	OFF	
01	OFF	ON	The Idle acknowledge signal is asserted when there are no pending activities on the functional and OCP clock domains (Improved latency in assertion of Idle acknowledge). The Wake-up capability of the module is disabled.
00	OFF	OFF	

This wake-up request is effectively sent only if the field ENAWAKEUP of TIOCP_CFG enables the timer wake-up capability. When the system is awaken, the Idle Request signal goes inactive and the wake-up request signal is also de-asserted.

Figure 19-37. Wake-up Request Generation



19.2.3.7.1 Wake-up Line Release

When the host processor receives a wake-up request issued by the timer peripheral, the interface clock is re-activated: the host processor deactivates the PIOCPMIDLEREQ, the timer deactivates the POROCPSIDLEACK signal and then the host can read the corresponding bit in TISR to find out which interrupt source has triggered a wake-up request. After acknowledging the wake-up request, the processor resets the status bit and releases the interrupt line by writing a ‘1’ in the corresponding bit of the TISR register.

19.2.3.8 Timer Counting Rate

The dmtimer’s counter is composed of a prescaler stage and a timer counter.

The prescaler clock ratio can be managed by accessing the ratio definition field of the control register (PTV and PRE of TCLR).

The timer rate is defined by:

- The value of the prescaler fields (PRE and PTV of TCLR register)
- The value loaded into the Timer Load Register (TLDR).

Table 19-35. Prescaler Clock Ratios Value

PRE	PTV	Divisor (PS)
0	X	1
1	0	2
1	1	4
1	2	8
1	3	16
1	4	32

Table 19-35. Prescaler Clock Ratios Value (continued)

PRE	PTV	Divisor (PS)
1	5	64
1	6	128
1	7	256

The timer rate equation is as follows:

(0xFFFF FFFF – TLDR + 1) x timer Clock period x Clock Divider (PS)

With timer Clock period = 1/ timer Clock frequency and PS = 2(PTV + 1).

As example, if we consider a timer clock input of 32 KHz, with a PRE field equals to “0”, the timer output period is:

Table 19-36. Value and Corresponding Interrupt Period

TLDR	Interrupt Period
0x0000 0000	37 h
0xFFFF 0000	2 s
0xFFFF FFF0	500 us
0xFFFF FFFE	62.5 us

19.2.3.9 Timer Behavior During Emulation

To configure the Timer to stop during emulation suspend events (for example, debugger breakpoints), set up the Timer and the Debug Subsystem:

1. Set TIOCP_CFG.EMUFREE=0. This will allow the Suspend_Control signal from the Debug Subsystem (Chapter 31) to stop and start the Timer. Note that if EMUFREE=1, the Suspend_Control signal is ignored and the Timer is free running regardless of any debug suspend event. This EMUFREE bit gives local control from a module perspective to gate the suspend signal coming from the Debug Subsystem.
2. Set the appropriate xxx_Suspend_Control register = 0x9, as described in Section 31.1.1.1, *Debug Suspend Support for Peripherals*. Choose the register appropriate to the peripheral you want to suspend during a suspend event.

19.2.4 DMTIMER_1MS Registers

Table 19-37 lists the memory-mapped registers for the DMTIMER_1MS. All register offset addresses not listed in Table 19-37 should be considered as reserved locations and the register contents should not be modified.

5	EMUFREE	R/W	0h	Sensitivity to emulation (debug) suspend event from Debug Subsystem. 0h (R/W) = Timer counter frozen during a debug suspend event. 1h (R/W) = Timer counter free-running. Debug suspend event is ignored.
4-3	IDLEMODE	R/W	0h	Power Management, req/ack control 0h (R/W) = Force-idle. An idle request is acknowledged unconditionally 1h (R/W) = No-idle. An idle request is never acknowledged 2h (R/W) = Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module. The module may generate wakeup events when in idle state. 3h (R/W) = reserved do not use
2	ENAWAKEUP	R/W	0h	Wake-up feature global control 0h (R/W) = No wakeup line assertion in idle mode 1h (R/W) = Wakeup line assertion enabled in smart-idle mode
1	SOFTRESET	Rreturns0s/W	0h	Software reset. This bit is automatically reset by the hardware. During reads, it always return 0 0h (R/W) = Normal mode 1h (R/W) = The module is reset
0	AUTOIDLE	R/W	0h	Internal OCP clock gating strategy 0h (R/W) = OCP clock is free-running 1h (R/W) = Automatic OCP clock gating strategy is applied, based on the OCP interface activity

19.2.4.3 DMTIMER_1MS_TISTAT Register (offset = 14h) [reset = 0h]

Register mask: FFFFFFFEh

DMTIMER_1MS_TISTAT is shown in Figure 19-40 and described in Table 19-40.

This register provides status information about the module, excluding the interrupt status information

19.3 Sync Timer (32k)

19.3.1 Introduction

The SyncTimer32K module is a 32-bit counter clocked by the falling edge of a 32-kHz clock. The timer is reset to its default value when its input pin, NRESPWRON, is active low (on a global cold reset). When NRESPWRON is released, and after three 32-kHz clock periods, the counter will start counting on the falling edge of the clock. When the highest count value is reached, the counter wraps to zero and continues counting without any extra delay. Counting can be temporarily stopped by asserting MSUSPEND (active low).

19.3.1.1 Sync Timer (32k) Features

The general features of the SyncTimer32K module are:

- Counter Register (32 bit) is an incremented counter
- Counter Register is incremented on falling edge of 32KHz clock.
- Counter Register can be cleared by NRESPWRON assertion.
- Counter Register can be stopped using MSUSPEND
- Hardware revision of the module can be read by OCP interface (ID_TIM).
- Counter Register value can be read by OCP interface with 32-bit OCP read access or 16-bit OCP access.
  - In case of 16-bit access, a shadow register will be updated on 16-bit LSB read command. This means that, to read a coherent value and avoid side effect, OCP 16-bit LSB command must be performed before OCP 16-bit MSB.
  - In addition, to keep coherency of the data, no interleaved accesses (from different OCP registers) are allowed.
- OCP 2.0 support
- WR and WRNP are supported and treated the same way

19.3.1.2 Unsupported Features

The SyncTimer32K module does not support the following features.

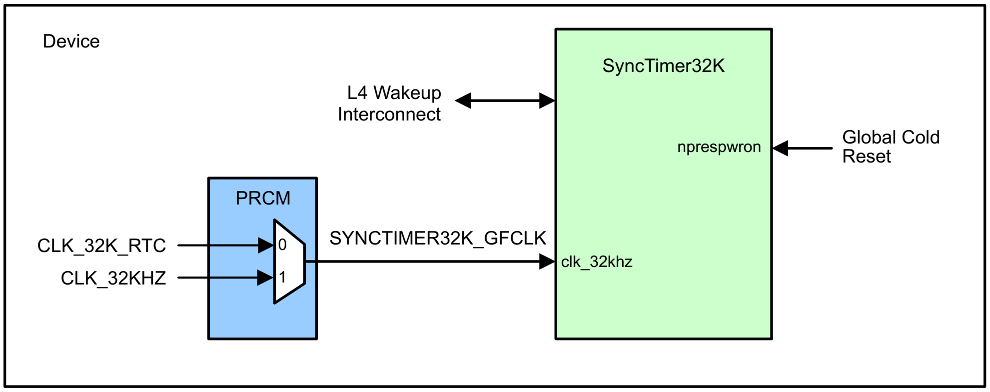
Table 19-58. Unsupported timer_32k Features

Feature	Reason
External event counter reset	Reset input not pinned out

19.3.2 Integration

This device contains a single SyncTimer32K module in the wake-up domain. Figure 19-58 shows the integration of the SyncTimer32K module in this device.

Figure 19-58. SyncTimer32K Integration



19.3.2.1 SyncTimer32K Connectivity Attributes

The general connectivity attributes for the SyncTimer32k module are shown in Table 19-59.

Table 19-59. timer_32k Connectivity Attributes

Attributes	Type
Power Domain	Wakeup domain
Clock Domain	PD_WKUP_L4_WKUP_AON_GCLK (OCP) SYNCTIMER32K_GFCLK (Functional)
Reset Signals	WKUP_DOM_RST_N

Physical Address	L4 wakeup slave port

19.3.2.2 SyncTimer32K Clock and Reset Management

The functional clock source (CLK_32KHZ input) is selected by the CLKSEL_SYNCTIMER_CLK register of the PRCM from:

- The RTC oscillator (CLK_32K_RTC)
- The PER PLL generated 32.768 KHz clock (CLK_32KHZ)

Table 19-60. SyncTimer32K Clock Signals

Clock Signal	Maximum Frequency	Reference Source	Comments
ocp_clk Interface clock	26 MHz	CLK_M_OSC	pd_wkup_l4_kwup_aon_gclk from PRCM
clk_32khz Functional clock	32.768 kHz	CLK_32K_RTC CLK_32KHZ (PER_CLKOUTM2 / 5859.375)	synctimer32k_gfclk from PRCM

19.3.2.3 SyncTimer32K Pin List

The SyncTimer32K has a single external interface signal.

Table 19-61. SyncTimer32K Pin List

Pin	Type	Description
NRESPWRON	I	Clear timer (when low)

19.3.3 Functional Description

The SyncTimer32K is a synchronized 32-bit counter clocked by the falling edge of a 32-kHz system clock. It is reset with asynchronous power on reset (NRESPWRON). When NRESPWRON is released, and after three 32-kHz clock periods, the counter starts counting from the reset value of the counter register on the falling edge of the 32-kHz clock. After reaching its maximum value, the counter wraps to zero and starts counting again.

19.3.3.1 OCP Interfacing

The SyncTimer32K has a 32-bit OCP interface. Due to the ocp_clk versus the clock of the peripheral frequency ratio, the ocp_clk is used to resynchronize the counter value for any ocp access.

The OCP bus interface handles:

- OCP bus peripheral address decoding
- Counter value read transaction synchronization to ensure the data correctness despite the asynchronous OCP and counter clocks
- OCP scmdaccept flag generation, synchronous with ocp_clk rising edge

19.3.3.2 Reading the Counter Register (CR)

Internal synchronization logic allows reading the counter value while the counter is running. Since the OCP is completely asynchronous with the 32-kHz clock, some synchronization is done, so as to make sure that the CR value is not read while it is being incremented. The synchronous logic ensures the read transaction correctness by synchronizing the counter register read access on the ocp_clk clock signal.

The counter register is a 32-bit “atomic datum” and has 16-bit capture. To read the value of CR correctly, the first OCP read access has to be to the lower 16-bit, followed by OCP read access to the upper 16-bit. Software performs a 32-bit access on the register while the device performs two consecutive 16-bit transactions. The time latency to read a synchronized register is one ocp_clk period.

In 16-bit mode, the following sequence must be followed to read the CR register properly:

a. Perform an OCP Read Transaction to read the lower 16-bit of the CR register.

   When the CR is read and synchronized, the lower 16-bit ‘LSB’ are driven onto the “ocp_sdata” bus and the upper 16-bit of the CR ‘MSB’ register are stored in a temporary register.

b. Perform an OCP Read Transaction to Read the upper 16-bit of the CR register.

   During this read, the value of the upper 16-bit ‘MSB’ that has been stored in a temporary register is forwarded onto the “ocp_sdata” bus.

19.3.3.3 Interrupt Control

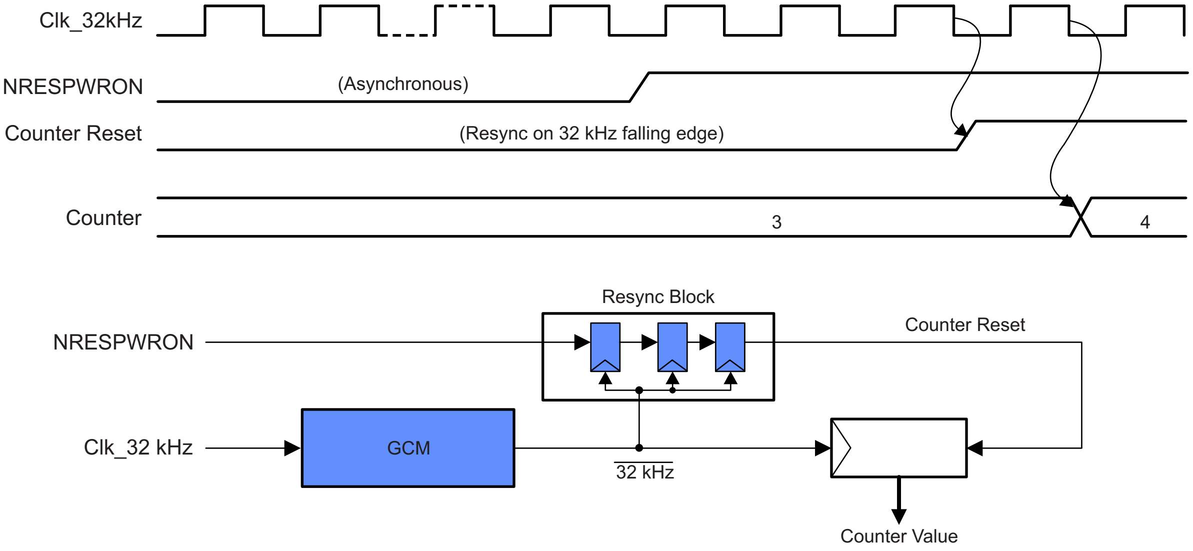
The SyncTimer32K has no interrupt outputs.

19.3.3.4 Reset

The NRESPWRON signal that is resynchronized three times on the rising edge of the inverted 32-kHz clock is used to synchronously reset the CR register.

The ocp_reset_n signal is used to asynchronously reset the OCP interface.

Figure 19-59. Reset Resynchronization Timing



19.3.4 SYNCTIMER Registers

Table 19-62 lists the memory-mapped registers for the SYNCTIMER. All register offset addresses not listed in Table 19-62 should be considered as reserved locations and the register contents should not be modified.

19.4 Real-Time Clock (RTC)

19.4.1 Introduction

The real-time clock is a precise timer which can generate interrupts on intervals specified by the user. Interrupts can occur every second, minute, hour, or day. The clock itself can track the passage of real time for durations of several years, provided it has a sufficient power source the whole time.

The basic purpose for the RTC is to keep time of day. The other equally important purpose of RTC is for Digital Rights management. Some degree of tamper proofing is needed to ensure that simply stopping, resetting, or corrupting the RTC does not go unnoticed so that if this occurs, the application can re-acquire the time of day from a trusted source. The final purpose of the RTC is to wake the rest of chip up from a power down state.

Alarms are available to interrupt the CPU at a particular time, or at periodic time intervals, such as once per minute or once per day. In addition, the RTC can interrupt the CPU every time the calendar and time registers are updated, or at programmable periodic intervals.

19.4.1.1 Features

The real-time clock (RTC) provides the following features:

- 100-year calendar (xx00 to xx99)
- Counts seconds, minutes, hours, day of the week, date, month, and year with leap year compensation
- Binary-coded-decimal (BCD) representation of time, calendar, and alarm
- 12-hour clock mode (with AM and PM) or 24-hour clock mode
- Alarm interrupt
- Periodic interrupt
- Single interrupt to the CPU
- Supports external 32.768-kHz crystal or external clock source of the same frequency

19.4.1.2 Unsupported RTC Features

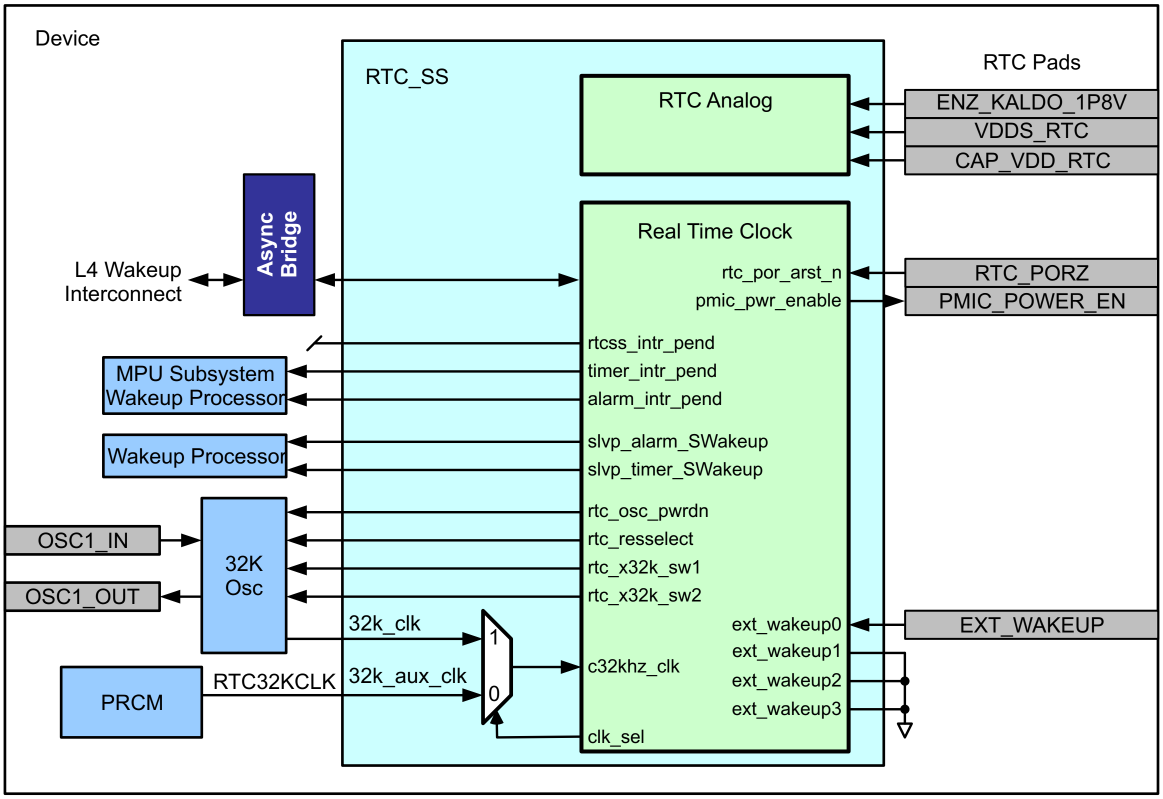
This device supports only a single RTC external wake-up event.

19.4.2 Integration

This device includes a Real-Time Clock Subsystem (RTCSS) module to allow easy tracking of time and date and the generation of real time alarms.

The integration of the RTC is shown in .

Figure 19-63. RTC Integration



19.4.2.1 RTC Connectivity Attributes

The general connectivity for the RTC module in the device is shown in Table 19-66.

Table 19-66. RTC Module Connectivity Attributes

Attributes	Type
Power Domain	RTC
Clock Domain	PD_RTC_L4_RTC_GCLK (Interface/OCP) PD_RTC_RTC32KCLK (Func) CLK_32K_RTC (Func)
Reset Signals	RTC_DOM_RST_N
Idle/Wakeup Signals	Smart Idle
Interrupt Requests	4 Interrupts Alarm interrupt to MPU Subsystem (RTCINT) and Wakeup Processor Timer interrupt to MPU Subsystem (RTCALARMINT) and Wakeup Processor Alarm wakeup to Wakeup Processor Timer wakeup to Wakeup Processor
DMA Requests	None
Physical Address	L4 Wakeup slave port

19.4.2.2 RTC Clock and Reset Management

The RTC functional clock (c32khz_clk input) is sourced by default from the CLK32_KHZ clock derived from the Peripheral PLL. It can also be sourced from the 32-KHz oscillator through a clock mux within and controlled by the RTC_SS.

Table 19-67. RTC Clock Signals

Clock Signal	Max Freq	Reference / Source	Comments
ocp_clk (Interface clock)	26 MHz	CLK_M_OSC	pd_rtc_l4_rtc_gclk From PRCM
rtc_32K_clk_rtc_32k_clk (Oscillator functional clock)	32.768 KHz	OSC1_IN	CLK_32K_RTC From OSC1_IN
rtc_32k_clk_rtc_32k_aux_clk (Internal functional clock)	32.768 KHz	PER_CLKOUTM2 / 5859.3752	pd_rtc_rtc_32kclk From PRCM

19.4.2.3 RTC Pin List

The RTC module does not include any external interface pins.

Table 19-68. RTC Pin List

Pin	Type	Description
RTC_PORz	I	RTC Power On Reset
EXT_WAKEUP	I	External wakeup
PMIC_POWER_EN	O	Power enable control for external power management IC
Analog Signals		
ENZ_KALDO_1P8V	I	Enable 1.8V LDO
VDDS_RTC	P	1.8V Voltage Supply
CAP_VDD_RTC	A	Decoupling Cap when internal 1.8 V LDO is enabled, 1.1 V supply when internal 1.8 V LDO is disabled.

19.4.3 Functional Description

This section defines the module interrupt capabilities and requirements.

19.4.3.1 Functional Block Diagram

Figure 19-64 shows the RTC module block diagram. Figure 19-65 shows a functional block diagram of the RTC.

Figure 19-64. RTC Block Diagram

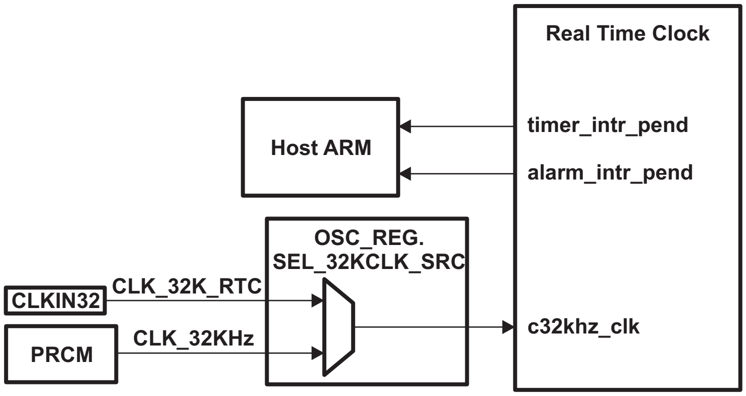


Figure 19-65. RTC Functional Block Diagram

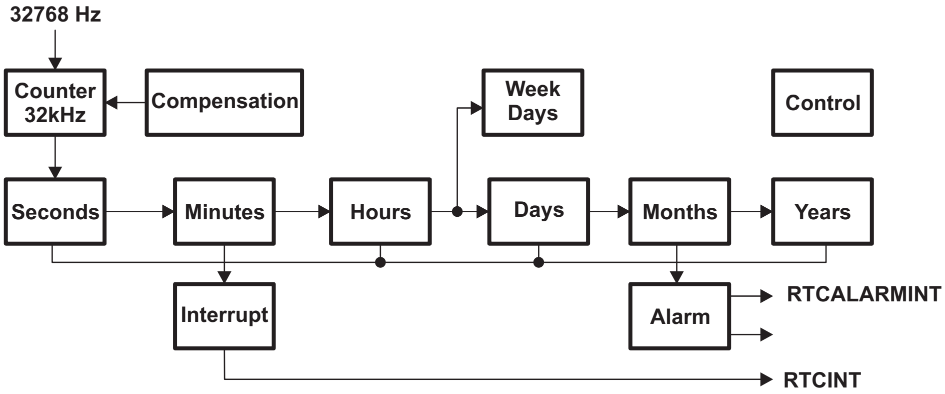


19.4.3.2 Clock Source

The clock reference for the RTC can be sourced from an external crystal (used with the 32K RTC Oscillator), an external 32KHz oscillator, or from the Peripheral PLL. The RTC has an internal oscillator buffer to support direct operation with a crystal. The crystal is connected between pins RTC_XTALIN and RTC_XTALOUT. RTC_XTALIN is the input to the on-chip oscillator and RTC_XTALOUT is the output from the oscillator back to the crystal. The oscillator can be enabled or disabled by using the RTC_OSC_REG register. For more information about the RTC crystal connection, see your device-specific data manual.

An external 32.768-kHz clock oscillator may be used instead of a crystal. In such a case, the clock source is connected to RTC_XTALIN, and RTC_XTALOUT is left unconnected.

The source of the 32-KHz clock is selected using the OSC_CLK.SEL_32KCLK_SRC bit.

If the RTC is not used, the RTC_XTALIN pin should be held low and RTC_XTALOUT should be left unconnected. The RTC_disable bit in the control register (CTRL_REG) can be set to save power; however, the RTC_disable bit should not be cleared once it has been set. If the application requires the RTC module to stop and continue, the STOP_RTC bit in CTRL_REG should be used instead.

19.4.3.3 Signal Descriptions

Table 19-69 lists the signals and their descriptions for the RTC.

Table 19-69. RTC Signals

Signal	I/O	Description
RTC_XTALIN	I	RTC time base input signal. RTC_XTALIN can either be driven with a 32.768-kHz reference clock, or RTC_XTALIN and RTC_XTALOUT can be connected to an external crystal. This signal is the input to the RTC internal oscillator.
RTC_XTALOUT	O	RTC time base output signal. RTC_XTALOUT is the output from the RTC internal oscillator. If a crystal is not used as the time base for RTC_XTALIN, RTC_XTALOUT should be left unconnected.

19.4.3.4 Interrupt Support

19.4.3.4.1 CPU Interrupts

The RTC generates two interrupt outputs:

- timer_intr (RTCINT) is a timer interrupt.
- alarm_intr (RTCALARMINT) is an alarm interrupt.

NOTE: Both interrupt outputs support high-level and high-pulse.

19.4.3.4.2 Interrupt Description

19.4.3.4.2.1 Timer Interrupt RTCINT (timer_intr)

The timer interrupt can be generated periodically: every second, every minute, every hour, or every day (see INTRS_REG[1:0] for a description of how to set this up). The IT_TIMER bit of the interrupt register enables this interrupt. The timer interrupt is active-low.

The RTC_STS_REG[5:2] are only updated at each new interrupt and occur according to Table 19-70. For example, bit 2 (SEC) will always be set when one second has passed. It will also be set when one minute has passed since the completion of one minute also marks the completion of one second (from 59 seconds to 60 seconds). The same holds true for hours and days: each of them will also correspond to the passing of a second.

Conversely, bit 5 (DAY) will always be set when a day has passed. It might also be set when an hour, minute, or second has passed. However, this only occurs when the elapsed hour, minute, or second corresponds to the start of a new day.

Table 19-70. Interrupt Trigger Events

	One day has passed	One hour has passed	One minute has passed	One second has passed
STS_REG[5] (DAY)	1	0/1 (1)	0/1 (1)	0/1 (1)
STS_REG[4] (HOUR)	1	1	0/1 (1)	0/1 (1)
STS_REG[3] (MIN)	1	1	1	0/1 (1)
STS_REG[2] (SEC)	1	1	1	1

(1) This event is only triggered when the elapsed time unit (for example, Day) corresponds to the passage of another unit (for example, Seconds). For example, when the clock ticks from 00:23:59:59 (days : hours : minutes : seconds) to 01:00:00:00.

19.4.3.4.2.2 Alarm Interrupt RTCALARMINT (alarm_intr)

The alarm interrupt can be generated when the time set into TC ALARM registers is exactly the same as in the TC registers. This interrupt is then generated if the IT_ALARM bit of the interrupts register is set. This interrupt is low-level sensitive. RTC_STS_REG[6] indicates that IRQ_ALARM_CHIP has occurred. This interrupt is disabled by writing ‘1’ into the RTC_STS_REG[6].

To set up an alarm:

- Modify the ALARM_SECONDS, ALARM_MINUTES, ALARM_HOURS, ALARM_DAY, ALARM_WEEK, ALARM_MONTH, and ALARM_YEAR registers to the exact time you want an alarm to generate.
- Set the IT_ALARM bit in the RTC_INTRS register to enable the alarm interrupt.

19.4.3.5 Programming/Usage Guide

19.4.3.5.1 Time/Calendar Data Format

The time and calendar data in the RTC is stored as binary-coded decimal (BCD) format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. Although most of the time/calendar registers have 4 bits assigned to each BCD digit, some of the register fields are shorter since the range of valid numbers may be limited. For example, only 3 bits are required to represent the day of the week (WEEKS_REG) since only BCD numbers 1 through 7 are required. The following time and calendar registers are supported (BCD Format):

Note that the ALARM registers which share the names above also share the same BCD formatting.

- SECOND - Second Count (00-59)
- MINUTE - Minute Count (00-59)
- HOUR - Hour Count (12HR: 01-12; 24HR: 00-23)
- DAY - Day of the Month Count (01-31)
- WEEK - Day of the Week (0-6: SUN = 0)
- MONTH - Month Count (01-12; JAN = 1)
- YEAR - Year Count (00-99)

19.4.3.5.2 Register Access

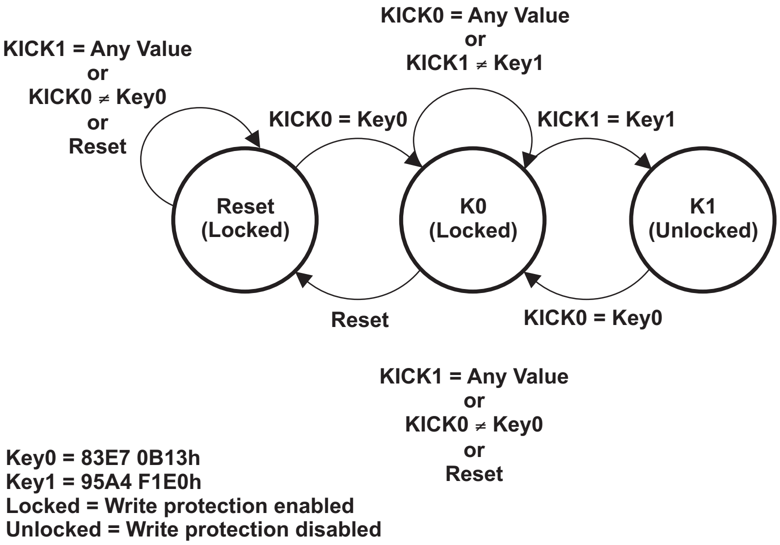
The three register types are as follows and each has its own access constraints:

- TC and TC alarm registers
- General registers
- Compensation registers

19.4.3.5.3 OCP MMR Spurious WRT Protection

The module also contains a kicker mechanism (Figure 19-66) to prevent any spurious writes from changing the register values. This mechanism requires two MMR writes to the Kick0 and Kick1 registers with exact data values before the kicker lock mechanism is released. Once released, the MMRs are writeable. The Kick0 data is 83E7 0B13h; the Kick1 data is 95A4 F1E0h. Note that it remains in an unlocked state until an OCP reset or invalid data pattern is written to one of the Kick0 or Kick1 registers.

Figure 19-66. Kick Register State Machine Diagram



- S0 is the Reset/Idle state
- S1 is an OCP wrt cycle of 83E7 0B13h at Kick0 completed state
- S2 is the UNLOCK MMR WRT state
- S0 -> S1 when OCP wrt cycle of 83E7 0B13h at Kick0
- S1 -> S2 when OCP wrt cycle of 95A4 F1E0h at Kick1
- S1 -> S0 when OCP reset event
- S2 -> S0 when OCP reset event OR OCP wrt cycle of NOT 83E7 0B13h at Kick0 OR OCP wrt cycle at Kick1
- S2 ->S1 when OCP wrt cycle of 83E7 0B13h at Kick0

19.4.3.5.4 Reading the Timer/Calendar (TC) Registers

The TC registers have a read-show register. The reading of the Seconds register will update all of the TC registers. For example, the Year will only get updated on a reading of the Seconds register. The time/calendar registers are updated every second as the time changes. During a read of the SECONDS register, the RTC copies the current values of the time/date registers into shadow read registers. This isolation assures that the CPU can capture all the time/date values at the moment of the SECONDS read request and not be subject to changing register values from time updates.

If desired, the RTC also provides a one-time-triggered minute-rounding feature to round the MINUTE:SECOND registers to the nearest minute (with zero seconds). This feature is enabled by setting the ROUND_30S bit in the control register (CTRL); the RTC automatically rounds the time values to the nearest minute upon the next read of the SECONDS register.

NOTE: Software should always read the Seconds register first. However, the software does not have to poll any status bit to determine when to read the TC registers. Table 19-71 defines the TC set that gets shadowed.

Table 19-71. RTC Register Names and Values

Time Unit	Range	Remarks
Year	00 to 99	
Month	01 to 12	
Day	01 to 31	Months 1, 3, 5, 7, 8, 10, 12
	01 to 30	Months 4, 6, 9, 11
	01 to 29	Month 2 (leap year)
	01 to 28	Month 2 (common year)
Week	00 to 06	Day of week
Hour	00 to 23	24 hour mode
	01 to 12	AM/PM mode
Minute	00 to 59	
Seconds	00 to 59	

19.4.3.5.4.1 Rounding Seconds

Time can be rounded to the closest minute, by setting the ROUND_30S bit of the control register. When this bit is set, TC values are set to the closest minute value at the next second. The ROUND_30S bit will be automatically cleared when rounding time is performed.

Example:

- If current time is 10H59M45S, round operation will change time to 11H00M00S.
- If current time is 10H59M29S, round operation will change time to 10H59M00S.

19.4.3.5.5 Modifying the TC Registers

To write correct data from/to the TC and TC alarm registers and read the TC alarm registers, the ARM must first read the BUSY bit of the STS register until BUSY is equal to zero. Once the BUSY flag is zero, there is a 15 µs access period in which the ARM can program the TC and TC alarm registers. Once the 15 µs access period passes, the BUSY flag has to be read again from the STS register as described previously. If the ARM accesses the TC registers outside of the access period, then the access is not guaranteed.

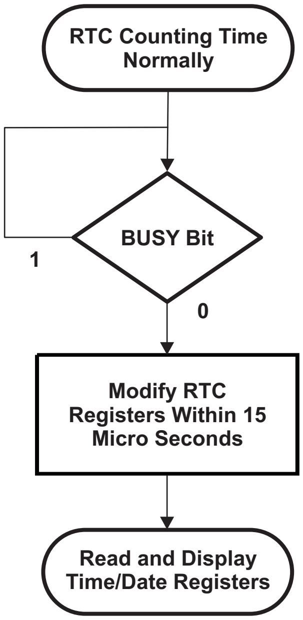
The ARM can access the STS_REG and CTRL_REG at any time, with the exception of CTRL_REG[5] which can only be changed when the RTC is stopped. The ARM can stop the RTC by clearing the STOP_RTC bit of the control register. After clearing this bit, the RUN bit in the STS_REG (bit 1) needs to be checked to verify the RTC has in fact stopped. Once this is confirmed, the TC values can be updated. After the values have been updated, the RTC can be re-started by resetting the STOP_RTC bit.

NOTE: After writing to a TC register, the user must wait 4 OCP clock cycles before reading the value from the register. If this wait time is not observed and the TC register is accessed, then old data will be read from the register.

CAUTION

In order to remove any possibility of interrupting the register's read process, thus introducing a potential risk of violating the authorized 15-microsecond access period, it is strongly recommended that you disable all incoming interrupts during the register read process.

Figure 19-67. Flow Control for Updating RTC Registers



19.4.3.5.5.1 General Registers

The ARM can access the STS_REG and the CTRL_REG at any time (except the CTRL_REG[5] bit which must be changed only when the RTC is stopped). For the INTRS_REG, the ARM should respect the available access period to prevent false interrupts.

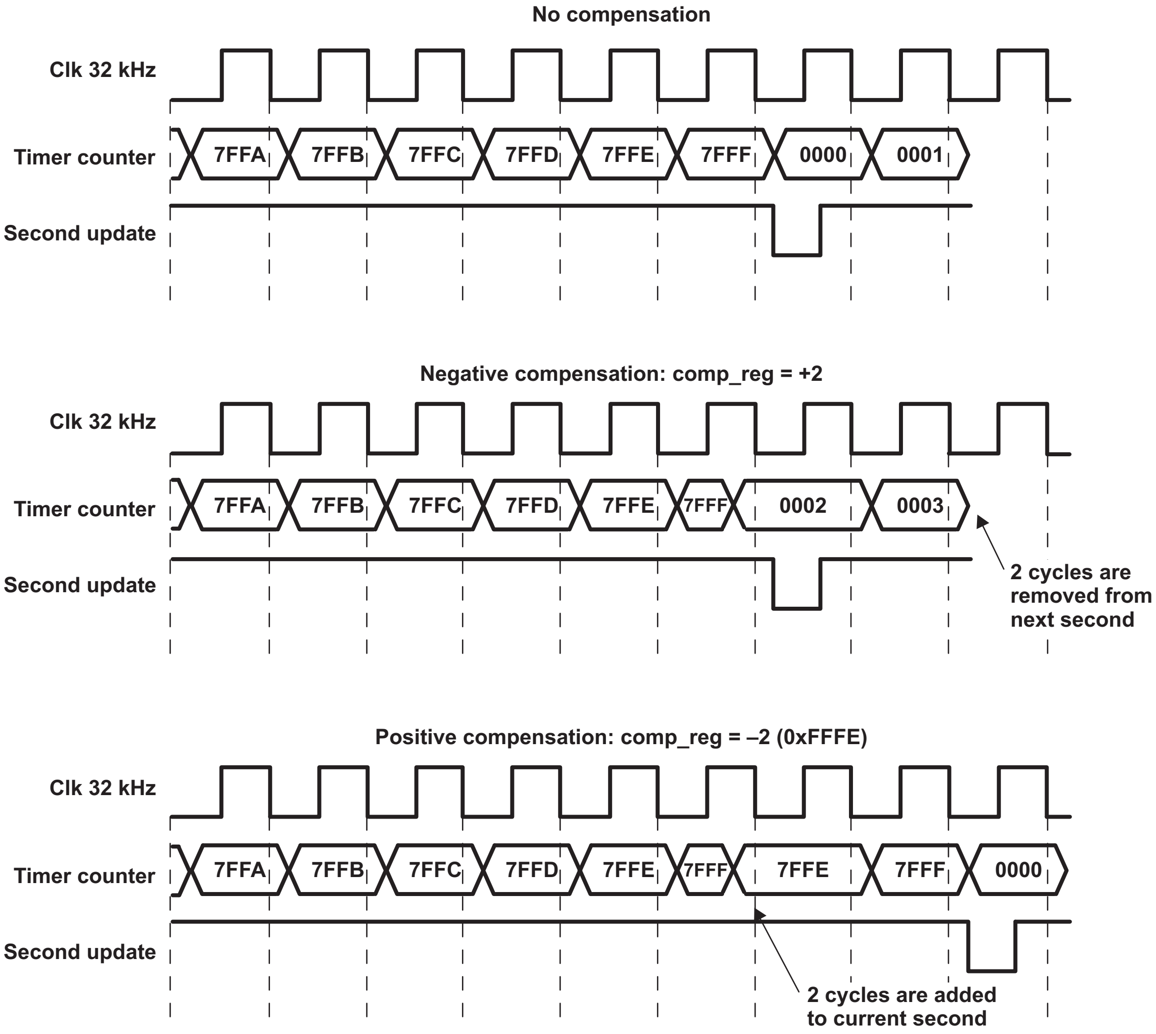
The RTC_DISABLE bit of the CTRL register must only be used to completely disable the RTC function. When this bit is set, the 32 kHz clock is gated, and the RTC is frozen. From this point, resetting this bit to zero can lead to unexpected behavior. In order to save power, this bit should only be used if the RTC function is unwanted in the application.

19.4.3.5.6 Crystal Compensation

To compensate for any inaccuracy of the 32 kHz oscillator, the ARM can perform a calibration of the oscillator frequency, calculate the drift compensation versus one-hour period, and load the compensation registers with the drift compensation value. Auto compensation is enabled by AUTO_COMP_EN bit in the RTC_CTRL register. If the COMP_REG value is positive, compensation occurs after the second change event. COMP_REG cycles are removed from the next second. If the COMP_REG value is negative, compensation occurs before the second change event. COMP_REG cycles are added to the current second. This enables compensation with a 1 32-kHz period accuracy each hour. The waveform below summarizes positive and negative compensation effect.

Access to the COMP_MSB_REG and COMP_LSB_REG registers must respect the available access period. These registers should not be updated during compensation (first second of each hour), but it is alright to update them during the second preceding a compensation event. For example, the ARM could load the compensation value into these registers after each hour event, during an available access period.

Figure 19-68. Compensation Illustration



19.4.3.6 Scratch Registers

The RTC provides three general-purpose registers (SCRATCHx_REG) that can be used to store 32-bit words -- these registers have no functional purpose for the RTC. Software using the RTC may find the SCRATCHx registers to be useful in indicating RTC states. For example, the SCRATCHx_REG registers may be used to indicate write-protection lock status or unintentional power downs. To indicate write-protection, the software should write a unique value to one of the SCRATCHx_REG registers when write-protection is disabled and another unique value when write-protection is enabled again. In this way, the lock-status of the registers can be determined quickly by reading the SCRATCH register. To indicate unintentional power downs, the software should write a unique value to one of the SCRATCHx_REG registers when RTC is configured and enabled. If the RTC is unintentionally powered down, the value written to the SCRATCH register is cleared. For more information, see Section 19.4.5, *RTC Registers*.

19.4.3.7 Power Management

The RTC supports the power idle protocol. It has two SWakeup ports: one for the alarm event and one for a timer event.

When the RTC is in IDLE mode, the OCP clock is turned off and the 32 kHz clock remains on. The time and calendar continue to count in IDLE mode. When the RTC is placed back in FUNCTIONAL mode, the TC registers can be read.

The Alarm SWakeup event can be used to wakeup the RTC when it is in IDLE state. In order to do so, the alarm needs to be set and enabled before RTC enters the IDLE state. Once this is done, the SWakeup will occur when the alarm event triggers.

NOTE: Since SWakeup is not periodic, using it to wake up the RTC when in IDLE state is not recommended. Please use Alarm SWakeup instead.

19.4.3.8 Power Management—System Level (PMIC Mode)

The RTC genertates pmic_power_en control which can be used to control an external PMIC.

Table 19-72. pmic_power_en Description

Port	Direction	Function
rtc_pwronrstn	Input	Not optional. RTC true power on domain reset. Only assert when RTC has lost power. Always de-assert when RTC voltage is greater than Vmin. The port remains de-asserted during normal operations.
pmic_power_en	Output	Optional. Can be used to control an external PMIC. 0 = OFF 1 = ON (reset state) ON → OFF (Turn OFF) By ALARM2 event OFF → ON (Turn ON) By ALARM event OR ext_wakeup event
ext_wakeup	Input	

19.4.4 Use Cases

The following list includes high-level steps to start using the RTC:

1. Enable the module clock domains (for details on which clock domain, see Section 19.4.2, *Integration*).
2. Enable the RTC module using CTRL_REG.RTC_disable.
3. Enable the 32K clock from PER PLL, if using the internal RTC oscillator.
4. Write to the kick registers (KICK0R, KICK1R) in the RTC.
5. Configure the timer in RTCSS for desired application (set time and date, alarm wakeup, and so on).
6. Start the RTC (in CTRL_REG.STOP_RTC).

19.4.5 RTC Registers

Table 19-73 lists the memory-mapped registers for the RTC. All register offset addresses not listed in Table 19-73 should be considered as reserved locations and the register contents should not be modified.

Table 19-73. RTC Registers

Offset	Acronym	Register Name	Section
0h	RTCSS_SECONDS_REG	Seconds Register	Section 19.4.5.1
4h	RTCSS_MINUTES_REG	Minutes Register	Section 19.4.5.2

19.4.5.1 RTCSS_SECONDS_REG Register (Offset = 0h) [reset = 0h]

RTCSS_SECONDS_REG is shown in Figure 19-69 and described in Table 19-74.

The SECONDS_REG is used to program the required seconds value of the current time. Seconds are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. If the seconds value is 45, then the value of SEC0 is 5 and value of SEC1 is 4.

19.4.5.2 RTCSS_MINUTES_REG Register (Offset = 4h) [reset = 0h]

RTCSS_MINUTES_REG is shown in Figure 19-70 and described in Table 19-75.

The MINUTES_REG is used to program the minutes value of the current time. Minutes are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. If the minutes value is 32, then the value of MIN0 is 2 and value of MIN1 is 3.

19.4.5.3 RTCSS_HOURS_REG Register (Offset = 8h) [reset = 0h]

RTCSS_HOURS_REG is shown in Figure 19-71 and described in Table 19-76.

The HOURS_REG is used to program the hours value of the current time. Hours are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. In 24Hr time mode if you want to set the hour as 18, then HOUR0 is set as 8 and HOUR1 is set as 1.

19.4.5.4 RTCSS_DAYS_REG Register (Offset = Ch) [reset = 1h]

RTCSS_DAYS_REG is shown in Figure 19-72 and described in Table 19-77.

The DAYS_REG is used to program the day of the month value of the current date. Days are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. If the day value of the date is 28, DAY0 is set as 8 and DAY1 is set as 2.

19.4.5.5 RTCSS_MONTHS_REG Register (Offset = 10h) [reset = 1h]

RTCSS_MONTHS_REG is shown in Figure 19-73 and described in Table 19-78.

The MONTHS_REG is used to set the month in the year value of the current date. Months are stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. Usual notation is taken for month value: 1 = January, 2 = February, continuing until 12 = December.

19.4.5.6 RTCSS_YEARS_REG Register (Offset = 14h) [reset = 0h]

RTCSS_YEARS_REG is shown in Figure 19-74 and described in Table 19-79.

The YEARS_REG is used to program the year value of the current date. The year value is represented by only the last 2 digits and is stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. The year 1979 is programmed as 79 with YEAR0 set as 9 and YEAR1 set as 7.

19.4.5.7 RTCSS_WEEKS_REG Register (Offset = 18h) [reset = 0h]

RTCSS_WEEKS_REG is shown in Figure 19-75 and described in Table 19-80.

The WEEKS_REG is used to program the day of the week value of the current date. The day of the week is stored as BCD format. In BCD format, the decimal numbers 0 through 9 are encoded with their binary equivalent. Sunday is treated as 0, Monday 1, and ending at Saturday with 6.

19.4.5.14 RTCSS_CTRL_REG Register (Offset = 40h) [reset = 0h]

RTCSS_CTRL_REG is shown in Figure 19-82 and described in Table 19-87.

The RTC_CTRL_REG contains the controls to enable/disable the RTC, set the 12/24 hour time mode, to enable the 30 second rounding feature, and to STOP/START the RTC. The SET_32_COUNTER bit must only be used when the RTC is frozen. The RTC_DISABLE bit must only be used to completely disable the RTC function. When this bit is set, the 32 kHz clock is gated and the RTC is frozen. From this point, resetting this bit to zero can lead to unexpected behavior. This bit should only be used if the RTC function is unwanted in the application, in order to save power. MODE_12_24: It is possible to switch between the two modes at any time without disturbing the RTC. Read or write is always performed with the current mode. Auto compensation is enabled by the AUTO_COMP bit. If the COMP_REG value is positive, compensation occurs after the second change event. COMP_REG cycles are removed from the next second. If the COMP_REG value is negative, compensation occurs before the second change event. COMP_REG cycles are added to the current second. This enables it to compensate with one 32-kHz period accuracy each hour. The ROUND_30S bit is a toggle bit; the ARM can only write 1 and the RTC clears it. If the ARM sets the ROUND_30S bit and then reads it, the ARM reads 1 until the round-to-the-closest-minute is performed at the next second. The ARM can stop the RTC by clearing the STOP_RTC bit (owing to internal resynchronization, the RUN bit of the status register (STATUS_REG) must be checked to ensure that the RTC is frozen), then update TC values, and re-start the RTC by resetting the STOP_RTC bit.

Bit	Field	Type	Reset	Description
2	AUTO_COMP	R/W	0h	Enable oscillator compensation mode. 0h (R/W) = No auto compensation 1h (R/W) = Auto compensation enabled
1	ROUND_30S	R/W	0h	Enable one-time rounding to nearest minute on next time register read. 0h (R/W) = No update 1h (R/W) = Time is rounded to the nearest minute
0	STOP_RTC	R/W	0h	Stop the RTC 32-kHz counter. 0h (R/W) = RTC is frozen 1h (R/W) = RTC is running

19.4.5.15 RTCSS_STS_REG Register (Offset = 44h) [reset = 0h]

RTCSS_STS_REG is shown in Figure 19-83 and described in Table 19-88.

The RTC_STATUS_REG contains bits that signal the status of interrupts, events to the processor. Status for the alarm interrupt and timer events are notified by the register. The alarm interrupt keeps its low level until the ARM writes 1 in the ALARM bit of the RTC_STATUS_REG register. ALARM2: This bit will indicate the status of the alarm interrupt. Writing a 1 to the bit clears the interrupt. ALARM: This bit will indicate the status of the alarm interrupt. Writing a 1 to the bit clears the interrupt. 1D_EVENT1: This bit will indicate if a day event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller. 1H_EVENT1: This bit will indicate if an hour event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller. 1M_EVENT1: This bit will indicate if a minute event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller. 1S_EVENT1: This bit will indicate if a second event has occurred. An interrupt will be generated to the processor based on the masking of the interrupt controller. RUN: This bit will indicate if RTC is frozen or it is running. The RUN bit shows the real state of the RTC. Indeed, because the STOP_RTC signal is resynchronized on 32-kHz clock the action of this bit is delayed. BUSY: This bit will give the status of RTC module. The Time and alarm registers can be modified only when this bit is 0. The timer interrupt is a negative edge sensitive low-level pulse (1 OCP cycle duration).

Table 19-88. RTCSS_STS_REG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-8	RESERVED	R	0h	
7	ALARM2	R/W	0h	Indicates that an alarm2 interrupt has been generated. Software needs to wait 31 us before it clears this status to allow pmic_pwr_enable 1 ' 0 transmission.
6	ALARM	R/W	0h	Indicates that an alarm interrupt has been generated
5	1D_EVT	R	0h	One day has occurred
4	1H_EVT	R	0h	One hour has occurred
3	1M_EVT	R	0h	One minute has occurred
2	1S_EVT	R	0h	One second has occurred
1	RUN	R	0h	RTC is frozen or is running. 0h (R/W) = RTC is frozen 1h (R/W) = RTC is running
0	BUSY	R	0h	Status of RTC module. 0h (R/W) = Updating event in more than 15 s 1h (R/W) = Updating event

19.4.5.16 RTCSS_INTRS_REG Register (Offset = 48h) [reset = 0h]

RTCSS_INTRS_REG is shown in Figure 19-84 and described in Table 19-89.

The RTC_INTERRUPTS_REG is used to enable or disable the RTC from generating interrupts. The timer interrupt and alarm interrupt can be controlled using this register. The ARM must respect the BUSY period to prevent spurious interrupt. To set a period timer interrupt, the respective period value must be set in the EVERY field. For example, to set a periodic timer interrupt for every hour, the EVERY field has to be set to 2. Along with this the IT_TIMER bit also has to be set for the periodic interrupt to be generated. IT_ALARM bit has to be set to generate an alarm interrupt.
